A cinematograph engineer, M. L. Lobel, who is well known in France, has recently completed the construction of an automatic film-printing equipment, the plans of which had been interrupted by the war. The machine consists, on the one hand, of a high-speed Prestotype printer without any intermittent movement, the negative film and sensitive positive band moving together horizontally at a uniform rate, which, without allowing for any masking, is from 1,500 to 3,000 images per minute. The printer is used in conjunction with a device which automatically varies the strength of the light according to the change of density in the negative band. This is done by providing notches in suitable positions on the edge of the negative film. The coming into position of a notch makes an electric contact which operates the light-varying device. The different strengths of light are produced by throwing an appropriate number of resistances into the lamp circuit, and these successive strengths of light are determined in advance by means of contact pins, which are fixed to a grating having eight vertical bars corresponding with resistances and forty horizontal bars corresponding with successive sections of the film negative. Errors are avoided in the positioning of these contacts by use of a perforated card which is laid upon the distribution table. This card is perforated to correspond with the densities of the various sections of the negative, and thus has only to be used, as a kind of stencil, in order to assure the necessary automatic variation of the light during printing.

A New Three-Colour Camera.

A new camera for the taking of the three-colour sensation negatives in rapid succession with one lens has just been constructed by M. H. Liabeuf, who has had a long experience in the making of cinematograph cameras, and during the war as a member of the Aerial Photographic Service invented an ingenious inclinometer for aerial cameras.

The three plates of 13 by 18 cm. size occupy the three faces of a prism of equilateral triangular section, the three screens being mounted on a disc, by which each is brought in turn in front of the lens. The special features of the camera are, first, the Maltese-cross mechanism, by which the plates and the screens are rapidly moved. In a portrait studio, under ordinary daylight (April), the three negatives have been made in two seconds on commercial panchromatic plates. The other feature is the daylight loading of the camera; the exposed plates can be removed and replaced by fresh without recourse to a dark-room.

L. P. Clerc.

DEATH OF MR. FRIESE-GREENE.

The daily newspapers have already given wide publicity to the sudden death, on Thursday in last week, May 5, of Mr. W. Friese-Greene, well known within the circles of photography, if not by the general public, as the inventor and maker of the first practical

The Late W. Friese-Greene.

cinematograph camera. Mr. Friese-Greene was present at a meeting of a film-exhibiting trade association, at which Lord Beaverbrook occupied the chair. He had risen to make a short speech, was taken suddenly ill, and expired within five minutes. He was in his 66th year.

There is no question that Friese-Greene was the pioneer in the creation of cinematography. The work of Muybridge, Marey, and others, which immediately preceded his invention, had for its object the recording of phases of movement. Various complicated cameras, usually fitted with a whole series of lenses, were designed for that purpose. The conception of means for the reproduction of movement, as perceived by the eye, was perhaps not original with Friese-Greene, but he certainly was the first man to make a camera which achieved this object. His patent specification, filed on June 21, 1889, in conjunction with an engineer named Evans, described the first practical instrument for taking photographs on an intermittently-moved flexible sensitive material. This camera was shown at the Bath Photographic Society early in 1890, and was exhibited by Mr. Friese-Greene at the Chester meeting of the Photographic Convention in July of the same year. It there attracted very little attention, for the contemporary reports described it simply as a camera for taking a series of photographs in rapid succession. Apparently the projector by which positives from the band negative were to be shown on the screen, and which Friese-Greene had already constructed during the early part of 1890, could not be used, on account of some derangement suffered in course of conveyance to Chester. The reproduction of the movement recorded by the camera, could it have been shown, would no doubt have demonstrated to members of the Convention the importance of the discovery. But already there were other inventors at work on the same problem, Edison in America, who was the practical introducer of perforated film; in France MM. Lumière, the inventors of the first efficient projecting machine, and Birt Acres, who was close on the heels of the French experimenters. A few years later it only remained for an imaginative Frenchman, M. Pathé, to conceive the idea of arranging for the acting of stories to be transferred to the cinematograph film. The technical work of Friese-Greene and those who followed him had then been done with sufficient completeness to allow of the cinematograph entering upon the enormous industrial development in the field of popular entertainment which the past few years have witnessed.

In a world of ideal justice, Friese-Greene should have made a handsome fortune; instead of which he died in poverty. Although we knew him well, and occasionally visited his workshops first at Chelsea and afterwards at Brighton, we knew little of the work which occupied him except that it seemed always to be connected with some fresh invention. Although he was an ingenious mechanician he had, so we judge, the very slightest acquaintance with the scientific elements of chemistry and physics. He impressed one as a child at play in a wonderful garden, made happy by discovering something fresh and incurably optimistic that some day and somehow or other fortune would fall into his lap. When it continuously failed to fall, a strain of oriental fatalism in his character preserved his cheerfulness; he forgot the disappointment and looked again to the future.

Apart from cinematography pure and simple his name is associated with early work in the production of stereoscopic cinematograph effects on the screen by means of viewing instruments fitted with filters of complementary colours. He was constantly engaged on experimental work in colour photography and colour cinematography, but as he scarcely ever wrote anything on the subject his labours can only be judged by the details published in patent specifications. One invention of his, which we believe was one of the most unfortunate from the financial standpoint, was that of inkless printing. It was proposed to impregnate printing paper with certain salts, which were decomposed by contact with metal type forming part of an electrical circuit. The decomposition products thus formed the impression on, or rather in, the paper. We believe a good deal of money was spent in the fruitless development of this invention, and, if rumour is correct, a certain disregard of company law brought the inventor into difficulties.

Naturally from those who in the cinematograph industry have made large fortunes, a debt of gratitude is due to Friese-Greene, and it is satisfactory to find that the cinematograph trade are interesting themselves in the circumstances of the dependents which he left behind. Posthumous honour has been more rapid than it is in most cases of this kind, but the tragic circumstances of his death have focussed attention upon the pioneer work of thirty years ago which, until a few days since, had almost been forgotten.

The Carbro Process.—An improved form of the Carbro process for the making of carbon prints from bromide prints or enlargements is described in a leaflet just published by the Autotype Company, 74, New Oxford Street, London, W.C.1. The working formulæ given in this leaflet are due to an amateur experimenter, Mr. F. Garon, and provide the improved facilities that the time of immersion in the bleaching or pigmenting both is now the same for all the Autotype tissues, with the exception of red chalk, namely, three minutes. Also, the quality of the resulting print is very much under control by simply varying the time of immersion in the second bath, which contains acetic acid, hydrochloric acid, and formaldehyde. A copy of the leaflet will be sent free on application.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

A Reliable Intensifier.

Although the usual mercuric chloride bleach intensifier, followed by darkening in either ammonia or sodium sulphite, has such a wide popularity among photographers, there are times when (either from the extremely poisonous nature of the mercury bath, or from the fact that negatives intensified in this way cannot be regarded as being anything like permanent) a reliable intensifier, giving absolutely permanent negatives, is required.

The method consists simply in making use of the ordinary ferricyanide-bromide bleach and sodium-sulphide sepia toning bath for intensifying negatives. Provided the negative has been thoroughly fixed and well washed, and the sulphide bath *freshly made up*, it will darken to a rich black image with identically the same degree of intensification as that given by the bichloride of mercury intensifier. It is very important that the sulphide should be obtained from a reliable source, such as Johnson's, of Finsbury (I have no ulterior interest in naming this firm), and also that the solution (normal strength) should be freshly made up. A stale sulphide bath, or impure sulphide, will only produce an image of a weak yellow-brown colour, with very serious loss of quality. In order that the bleaching may not take an unnecessarily long time, it is a good plan to make up the ferricyanide and bromide bleaching bath a little stronger than is required for toning prints. It goes without saying that, provided the negative is bleached right through, thoroughly darkened and properly washed, the results, after intensifying, may be regarded as being absolutely permanent. I claim no originality for this method, but it is not so well known as it might be. I therefore trust that fellow photographers will find it useful in their work.—A. J. Sweeney.

Exhibitions.

PORTRAITS BY WALTER THOMAS.

Mr. Walter Thomas, whose pictorial work has been a familiar feature at photographic exhibitions for as long as we can remember, is exhibiting at 147, New Bond Street (Davis Galleries) during the present month a collection of his sketches in charcoal and pastel and of portraits of legal luminaries. The latter are shown in special reference to Mr. Thomas's adoption, after a long life spent in legal circles, of professional portraiture, and particularly of at-home portraiture. In introducing himself to the public there is therefore a special fitness in his showing portraits of eminent lawyers, among them one of the Lord Chief Justice (Lord Justice Lawrence) taken a few days ago since his succession to Lord Reading. In landscape work, with pencil or camera, Mr. Thomas's style has always been that of the fresh, vigorous, outdoor school, taking a pleasure in the effects of Nature and, as regards his photographs, prizing the characteristic qualities of photography. That same outlook is exhibited in his portraiture. One finds here no indulgence in tricks and fakes of lighting such as may tickle a jaded palate, but often have the result of spoiling the portrait as a likeness. The lighting is in many cases evidently that of an ordinary room, yet—or should we say "yet"?—Mr. Thomas has obtained astonishingly virile and striking portraits, which owe their quality to the photography and not to retouching. A skilled technician as he is, Mr Thomas exhibits a sure hand in dealing with difficult subjects; for example, the portrait of the Lord Chief Justice shows marvellously fine technique in its monochrome rendering of the red robe and other insignia of office. Other portraits in the collection are those of Mr. Kemp, K.C., Recorder of Hull; Mr. Waugh, K.C., Recorder of Sheffield; Mr. Comptson, K.C., Recorder of Leeds; and Mr. Mitchel-Innes, K.C., Recorder of Middlesbrough. Men are evidently subjects in which Mr. Thomas takes a special pleasure, but the collection includes some charming studies of children, and is lightened by some of Mr. Thomas's pastel and pencil drawings of landscapes. The professional making of at-home photographs is a branch of portraiture which in this country has been largely neglected. Rightly or wrongly, from their point of view professional photographers have preferred to hold aloof from it. Mr. Thomas, however, intends to base his professional work on it, and since his artistic taste and technical skill assure beforehand the making of notable portraits, he has our best wishes in his enterprise.

FORTHCOMING EXHIBITIONS.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, April 11 to 16 :—

Reproduction Process.—No. 10,586. Photographic reproduction. Daylight Film Corporation and E. C. R. Marks.

Apparatus.—No. 10,962. Photographic apparatus. J. Evans.

Preserving Sensitised Surfaces.—No. 10,847. Method of and container for preserving sensitised surfaces. F. P. McColl.

Colour Photography.—No. 10,773. Colour sensitised supports for colour photography, etc., and treatment thereof. M. Martinez.

Camera Stands.—No. 10,612. Folding stands for photographic cameras, etc. Newman and Guardia, Ltd., and T. Peacock.

Distance Photography.—No. 11,018. Means for enabling images of pictures, moving objects, etc., to be visualised and photographed at a distance. W. A. Powell.

Photogrammetry.—No. 10,635. Photogrammetric survey. U. Nistri.

Cinematography.—No. 10,824. Portable cinematograph apparatus. N. E. Barber.

Cinematography.—No. 10,551. Method of winding and using cinematograph films. A. C. Broom.

Cinematography.—No. 11,124. Cinematography, etc. H. E. Coston and Holam, Ltd.

Cinematography.—No. 10,954. Picture films and apparatus for direct observation and projection of the same. C. Lepine.

Cinematography.—No. 10,529. Cinematograph, etc., screens. A. M. McLeod and A. L. Turner.

£1,000 Professional Portrait Competition.—The competition which is being announced by Messrs. Wellington and Ward is something quite fresh in the annals of photographic contests. £1,000 is offered in money prizes for the most beautiful portraits of ladies. And the essentially novel feature is that the sitter will receive a substantial proportion of the prize. Thus, the first prize is of £300 to the photographer, and £200 to the sitter; the second £200 to the photographer, and £100 to the sitter; whilst the third is £150 to the photographer, and £50 to the sitter. The competition is open to all bonâ fide professional photographers carrying on a business in the United Kingdom. All photographs must be printed on Wellington papers, from negatives made on Wellington plates. Messrs. Wellington and Ward have thus had the object of interesting the public through the photographer, and their idea must certainly have the effect of stimulating an interest in professional photographic portraiture. It is specially emphasised that the prizes will be awarded for the beauty of the photographs, and not necessarily for that of the sitters. It is desired to lay stress on the fact that the ordinary sitter will have as good a chance of winning one of the prizes as the member of a beauty chorus. Full particulars of the competition are available on application to Messrs. Wellington and Ward, Elstree, Herts.

New Books.

Le Guide de l'Operateur dans la Photogravure. By Louis Villemaire. Paris: Dunod. 12 francs.

This is a strictly practical manual on photo-engraving in monochrome and colours. M. Villemaire is instructor in the Estienne School in Paris, where instruction in photo-mechanical processes is given to apprentices in the printing trade. Thus, his text is closely in touch, from first to last, with practical manipulation, though not to the exclusion of methods of calculation where these come within his province. For example, he devotes a chapter to the use of the slide rule in making the optical calculations required in copying to scale. For the most part, however, he applies himself to the preparation and handling of the wet collodion plate, printing on metal by the fish-glue and other processes, the use of the screen in the half-tone process and the details of negative making and printing in three-colour block-making. The book is a very complete formulary for the developers, intensifiers, reducers, sensitisers, etc., employed in these processes, and it is evident that throughout, the author is writing of methods with which he is familiar by daily use.

The Electrical Transmission of Photographs. By Marcus J. Martin. London: Sir Isaac Pitman and Sons. 6s. net.

The reproduction of a photograph or drawing from one part to another of an electric circuit, and still more the viewing of a distant object by electrical means, are inventions of the utmost fascination even to the non-technical mind, and every now and again are the subject of articles prophesying the speedy revolution of the present methods of producing illustrated newspapers. Mr. Martin, in this volume, gives a sober and not too technical account of the stages through which these processes have passed, and of the limits within which at the present day they are capable of application in practice. Those limits, determined by different causes, continue to narrow the scope of such processes to a very considerable degree. We have still a long way to go before the telegraphed photograph is a more rapid method than the conveyance of the exposed plate on a motor bicycle. Nevertheless, the subject is of such novelty, and the possibilities which it holds in view include such far-reaching effects, that this straight-forward story of the technical means, chiefly electrical, by which such results are possible, will be read with more than ordinary interest. In a final chapter the author gives sufficiently detailed instructions and drawings for the making of a machine for experimental use in photo-telegraphy.

Air-Brush Technique.—The current issue, No. 181, of the "Photo-Miniature," is a manual on the use of the air-brush, which we are sure will do much to popularise this tool of the professional colourist and "finisher" of photographs among amateur workers, and very likely will tell many an experienced user of the air-brush one or two things which he did not know before. Our little contemporary, as always, is practical, yet contrives to make even the technical exercises of air-brush colouring a species of interesting adventure. A brief historical introduction which it gives reminds us that the air-brush originated in the United States, about 1886. Apparently all the air-brushes which are in successful use are of American design. Our own Aerograph is not an exception, for its inventor, Mr. C. L. Burdick, is an American, who, however, has made his home here for many years, and has established air-brush work in many industrial directions. The manual before us, while not attempting the profuse illustration of that by Mr. Stine, which we noticed a few months ago ("B.J.," November 12, 1920), is a thoroughly practical little work which leads the colourist by easy paths, and moreover shows the usefulness of the air-brush in other photographic operations, for example, in applying sensitising solutions. The "Photo-Miniature" is obtainable in this country from Messrs. Houghtons, price 1s. 8d.; in America, from Messrs. Tennant and Ward, 103, Park Avenue, New York, price 40 cents.

New Apparatus.

Salex Folding Focal Plane Camera. Sold by the City Sale and Exchange, 54, Lime Street, London, E.C.3.

These are distinctive models of folding camera, distinctive in the sense that they are fitted with focal-plane shutters, and thus provide the user of a highly portable instrument with the facility of making very rapid exposures. Two sizes of the camera are at present available, namely, vest-pocket and 3½ × 2½. As the drawing shows, the lens front is held by the customary system of spring struts, and is exceedingly rigid. A direct-vision lens finder comes into operation by raising the plate seen on the camera front. When lowered this plate serves as a protective shield for the lens. The camera is fitted with an *f*/5.5 anastigmat, and in both sizes has a focussing scale. The shutter has a quick wind, and is very easily adjusted for its full range of speeds by altering the width of the slit. This is done first by bringing one edge of the slit against the thousandth second mark on the scale; a stud on the

camera back is then pressed in and the winding knob of the shutter at the same time drawn slightly out, when the slit can be made wider or narrower as required. The shutter can be opened to the full width of the plate for focussing, but is not made for time exposures. For these, a very handy little separate attachment, in the shape of a flap shutter is provided to fit on the lens, and is operated by Antinous release. In the case of the 3½ × 2½ size, the Antinous release of this attachment can also be used for release of the focal plane shutter. The cameras are made for the use of either single metal plate holders or film pack adapter, and at the prices at which the vest pocket instrument is supplied, six single slides, as well as a film pack adapter, are included. This price is £6 17s. 6d. In 3½ × 2½ size the price of the outfit, including six single slides, is £8 17s. 6d., film pack adapter, 15s. extra. The instruments are exceedingly portable, and we have no doubt that amateur workers anxious to extend their field of work beyond the capacity of the speed of between-lens shutter will find them an excellent choice.

Photo Glovlettes.—Messrs. Fallowfield, 146, Charing Cross Road, London, W.C.2, have just introduced an improvement on the ordinary glove in the shape of these so-called "Glovlettes," which are a kind of skeleton glove, that is to say, the parts of the glove which ordinarily cover the palm and back of the hand are cut away. The article thus consists of a set of four rubber fingers

and a thumb, which is held in position on the hand by an elastic round the wrist. The "Glovlette" is much more conveniently put on, and while it affords a full degree of protection to the fingers from contact with photographic solutions, leaves the hands freer and cooler in use. No doubt many who are unable to wear the ordinary rubber glove in consequence of "that stuffy feeling" will find no objection to this new pattern, which certainly can be recommended to anyone susceptible to the action of developing or other solutions. The "Glovlettes" are supplied in two ladies' sizes and three men's sizes, price 5s. per pair.

New Materials.

PORTRAIT MOUNTS.—In sending us the latest list of their mounts and mounting boards, Messrs. Bartons, Cosway Works, Finch Road, Birmingham, give us the opportunity once again of renewing our acquaintance with the many excellent styles of their design and manufacture. We have on many occasions in the past had to write in terms of warm commendation in noticing these productions, for Messrs. Bartons' plainly keep a very high standard before them and are constantly discovering fresh forms in which to embody their ideas of tasteful mounts. The present collection of specimens only serves to confirm us in the good opinions we have previously held. It includes a great variety of most pleasing styles, mounts which owe their æsthetic qualities both to the delicate colours of the mounting papers, their refined figuring, and the skilful reserve with which the minimum amount of embellishment is added. The mounts are chiefly of the folder pattern, in accordance with the prevailing fashion, but a number include a species of combination of the old cut-out mount with the modern folder. Many of them are specially adapted for the use of the double-weight printing papers now much in vogue. We can recommend any portrait photographer who is not acquainted with these manufactures to see for himself the very artistic mountings which Messrs. Bartons' provide.

Commercial & Legal Intelligence.

NEW COMPANIES.

PHOTO-WORK, LTD.—This private company was registered on May 3 with a capital of £1,000 in £1 shares. Objects: To carry on the business of photographers, artists, art dealers, enlargers, gilders, picture-frame makers, etc. The subscribers (each with one share) are: B. H. Richardson, 22, Briggate, Brighouse, solicitor, and W. G. Robertshaw, 22, Briggate, Brighouse. The first directors are not named. Registered office: 22, Briggate, Brighouse.

INTERNATIONAL FIREPROOF CONDENSER AND LENS CO., LTD.—This private company was registered on May 3 with a capital of £1,000 in £1 shares. Objects: To exploit a patent condenser invented by A. Wood, and to carry on the business of patentees, engineers, glass makers, manufacturers of glassware, optical instruments, cinematograph accessories, machines, furniture, etc. The first directors are: J. H. G. Cutts, 126, Kenilworth Court, Putney, S.W., theatrical and entertainment producer; J. A. Ottway, 17, Blakesley Avenue, Ealing, W., optical instrument manufacturer; and A. Wood, "Llanberis," Haslemere Avenue, West Ealing, W. Qualification: One share. Remuneration as fixed by the company. Secretary: W. H. Davies. Registered office: 122 and 123, Moorgate Station Chambers, Moorgate Street, E.C.

HULL PHOTOGRAPHIC SOCIETY.—At the annual meeting Mr. R. Proudlove, M.Sc., B.Sc., was elected president, and Messrs. Anthony Wright, 73, Lairgate, Beverley, and Edgar Mennell, 10a, Spring Street, Hull, joint honorary secretaries.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, MAY 17.

Portsmouth Camera Club. "The Cornish Riviera." J. C. Thompson.

Scottish C.W.S.C.C. (Glasgow). Lecturette—"Flower Studies."

WEDNESDAY, MAY 18.

Bradford Photographic Society. Excursion to Tong Park.

Croydon Camera Club. "Croydon Waters." J. A. Sinclair.

FRIDAY, MAY 20.

R.P.S. Pictorial Group. "The Choice of a Lens." A. C. Banfield.

SATURDAY, MAY 21.

Rotherham Photographic Society. Excursion to York.

Scottish C.W.S.C.C. (Glasgow). Outing to Bothwell Castle.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, May 10, the president, Dr. G. H. Rodman, in the chair.

A note on "The Theory of the Screen in Half-Tone Work," by M. L. P. Clerc, was read, or rather presented in a more popular form, by Mr. Renwick in reference to the presentation by M. Clerc of a model to the Society illustrating his theory. The note was a brief abstract of the method of charting the field of a plate, receiving an image through the cross-line screen of the process camera, in such a way as to indicate the form of the dot elements composing the image. M. Clerc's note, in fact, closely followed his exposition of this subject in his manual, "Les Reproductions Photomecaniques."

A paper by Professor The Svedberg was also read by Mr. Renwick. It dealt with the action on the silver-bromide grains of dry-plates of alpha and beta particles. Professor Svedberg prefaced his notes on this subject by a brief discussion of the possible ultimate causes of the characteristic action of light on gelatine emulsion, which is represented by the form of the H. & D. curve. One such possible cause was diminution of the light by successive layers of grains; another was difference in the size and sensitiveness of grains; a third was the characteristic property of individual grains, and a fourth the behaviour, in this way, of classes of grains, the curve thus representing the sum of the effects on grains affected in different ways. The paper contained a mathematical examination of these various theories and was illustrated by curves of experimental results.

Mr. Renwick usefully added some notes on the relation of size of emulsion grain to sensitiveness, and stated that from the experience of twenty years in the making and examination of emulsions he was convinced that these qualities were not inter-dependent; in other words, that extreme sensitiveness was not incompatible with great fineness of grain.

Then followed Mr. K. C. D. Hickman, who, with much wit and good humour, related the story of a failure in the attempt to work out a new printing process. Briefly, Mr. Hickman was asked to provide a substitute for the well-known papers, such as ferro-prussiate and others, used for the copying of tracings. He had light-heartedly conceived the idea of coating paper with a mixture of methylene blue, ferric salt and other substances, in the aim of causing the formation of a colourless leuco derivative of the dye, by the action of the ferrous salt produced on exposure to light. Such a paper would, therefore, give a copy in blue lines on a white ground when exposed to light behind an ordinary tracing or drawing. But in spite of heroic attempts continued for several months and mercifully terminated by a motor cycle accident which Mr. Hickman sustained, the process had been found quite impracticable, a failure which, as Mr. Raymond E. Crowther pointed out, was due largely to the characteristic properties of the leuco derivatives of the dye.

Votes of thanks to the contributors and readers of the papers brought the meeting to an end.

CROYDON CAMERA CLUB.

Extensively billed, last week Mr. W. L. F. Wastell trod the boards. Famous in conducting an ever-pleasant page in a contemporary, which in delightfully humourous fashion often camouflages real instruction, some of the newer members had never seen the "Walrus" before and expressed their utmost gratification at witnessing him in the flesh. It happens that the "Walrus" has

himself defined the members as "a weird collection of human oddities," which doubtless accounts for this manifestation of eccentricity.

Hunting about almost at the last moment for a subject, of course he must choose one recently demonstrated at Croydon. Such is luck, but he rose superior to fate, and held a highly successful revivalist meeting on "Transferotype." It was ably dealt with about two months ago by Mr. S. H. Wratten after an intensive training of an hour or so by Kodak specialists. The "Walrus" had no such assistance, but brought with him the same old friends in the shape of Kodak specimen prints. On the other hand, he boasted of more experience of the subject, and some ideas which had long been scintillating in his brain burst into brilliant coruscations for the first time. This was really nice of him as, properly padded, they were capable of assuming the form of a remunerative article, but sordid considerations make no appeal to a noble soul which can even and invariably rise superior to "free samples." This almost incredible statement is made on the authority of this unique specimen of humanity, but without his knowledge or consent.

He started with a complete description of the process, repeating with great exactitude what Mr. Wratten had said previously. Mr. Wastell, however, much prefers a ten per cent. solution of formaline instead of alum as a hardening bath, and only a mere rinse is required afterwards. Amidol was strongly recommended as a developer, and if the bromide bottle happened to be within reach a few drops from it were added, but it did not seem to make much difference. With a correctly exposed print, the flagging action of amidol towards the end of development is, he said, very noticeable, and exposure should always be such that the print requires development to this stage, or, practically speaking, to infinity. This period of exposure he defined as "normal."

The utilisation of these stripping films for making lantern-slides was next considered. Mr. Wratten had contented himself by saying that he had been told at Harrow they made excellent slides, but he hardly carried conviction. The "Walrus" splashed an emphatic affirmation. They make first-rate slides, he said, and one suitable for feeble illuminants to a powerful arc can be produced with ease and certainty, multiplying the "normal exposure" by two for thin slides, and up to three-and-a-half times for dense ones. The simplicity and cheapness of the process should appeal to all, especially if they could cadge some of the many duds from makers of the usual sort, and employ them as supports and cover-glasses. In his hands no noticeable granularity occurred, and a very full range of tones and colour was possible.

At a recent meeting of the South Woodford Society, with "experts" present (this word was used in no offensive sense), no one, he said, could detect Transferotype slides among others of regulation type. He then passed round several slides for examination, but this did not do for Croydon, and in a jiffy Mr. Walker had the lantern going and they were put to the test. They stood it right well, and by universal consent were of splendid quality. At a distance of a few feet no granularity could be seen if any existed, though Mr. Harpur, who here apparently utilised the lantern-sheet as an emergency pocket handkerchief, said he detected some.

Mr. Wastell said Transferotypes are also well adapted for reproducing negatives permitting of much modification if necessary. If made by contact, double the normal exposure is right for both positive and reproduced negative. Two reversals being effected, it is the right way round. For the making of combination positives, again nothing can beat the stripping film for ease of working. Taking a familiar example, that of printing in clouds, the landscape portion (with sky, if printable, shaded in the usual way) is first transferred to the glass. Any remnants of sky are then removed with a soft brush charged with ferricyanide reducer, taking care to hold the positive landscape end up. When rinsed and dried the landscape portion is painted over with celluloid varnish, following the outlines carefully, and when the varnish has dried the clouds are transferred. Holding the positive this time sky-end up, any overlapping clouds are removed with the reducer, the celluloid varnish resisting penetration to the landscape. A fine brush enables small objects protruding over the sky to be similarly cleared. A point to remember is to print the clouds on a piece of paper long enough to cover the transparency, so that the edge of the film does not finally traverse the pictures. A great advantage consists in the fact that the exact position of the clouds can be observed through the back of the transparency.

He then passed round a first-rate transparency made in this way, and it may be remarked that if on high magnification a little granularity should result, a slight diffusion of definition, usual in pictorial work and beneficial in most, would probably entirely dissipate any grain. When it is stated that Croydon expressed its emphatic appreciation of this coruscation of the "Walrus," enough has been said.

In the discussion, Mr. Vivian Jobling, with no special reference to the present dreadful trade depression, was of opinion that lantern-plate makers would shortly go out of business. Mr. H. P. C. Harpur then rose, not looking in the best of spirits, and there was some excuse, for he thinks nothing of spending hours in reducing a 15 × 12 negative to abject submission with a No. 0 camel's-hair brush, and is the club's authority on the subject. No essential had been omitted by Mr. Wastell, or statement made open to correction, which, naturally, was rotten. However, the speaker declined to admit that the very, very finest lantern-slides could be made the Transferotype way, adding that in this "all must work out their own glorification," in fluffless blotting-paper, judging from the actual words following. A most hearty vote of thanks for an evening of exceptional interest was accorded the lecturer, who apparently had suffered no ill-effects from a cigar kindly presented him by the president. Others in the immediate vicinity were not so fortunate.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held on May 2. Present:—Miss Grey, Messrs. Yerbury, Fergusson, Melrose, E. D. Young, Campbell Harper, George Balmain, Swan Watson, Moffat, Norman Thomson, John Thomson, Philip, and Drummond Shiels.

There were also present, as guests of the Society, Mr. and Mrs. Debenham, Mrs. and Miss McKay, Messrs. Charles D. Crooke, Wm. Halkett, Hutchison, and Ross.

Mr. E. D. Young, the President, in the chair.

The Chairman, on behalf of the members, welcomed the guests, and shortly defined the objects of the Society. He stated that one of these was to promote a spirit of brotherhood amongst professional photographers, and endeavour to raise the status of their profession. He invited those guests present to join the Society, and he assured them that it would be for the mutual benefit of their business.

The Chairman conveyed the hearty congratulations of himself and the members to Mr. Swan Watson on his appointment as President of the P.P.A. for the ensuing year.

The Chairman reported that he had been present at the Congress in London, held last month, and found it most stimulating and helpful. The exhibitions and lantern lectures were most interesting, and he had derived great benefit from the discussions at which he had been present, and also from his meeting with the members of the profession in England.

Mr. Swan Watson returned thanks for the Society's congratulations, and stated that he was proud of the honour which had been conferred upon him, not only on behalf of himself, but also for the honour done to Edinburgh photographers. Mr. Swan Watson emphasised the Chairman's remarks as to the great value of the Congress, and the particularly high order of the lectures and illustrations. He stated he also had learned something from an exchange of experiences of how his professional brethren in England carried on their business.

Mr. Moffat thereafter explained the Committee's report on the prices for commercial photography, and exhibited to the meeting a specimen invoice showing how he suggested an account for commercial photography should be rendered. It was pointed out that the costing tables which had been prepared by the Committee were merely a guide for fixing charges to enable members to find out, under simple conditions, what the actual execution of commercial work would cost. The scheme was unanimously recommended by the meeting as a basis for a trial, and it was proposed that after the members had had experience of it for two or three

months, to again bring it before the Society for their further consideration and approval. Mr. Moffat was heartily thanked by the members for the trouble which he had spent on the preparation of the tables.

The Chairman stated that he was to see Mr. McNally, of the Education Authority, and ascertain if a trade class for photography could be instituted at the night schools, and report to the next meeting.

The election of office-bearers was then proceeded with, and Mr. E. D. Young, retiring President, moved that Mr. Campbell Harper be appointed President for the coming session. This was seconded by Mr. Balmain, and supported by Mr. Swan Watson. Mr. Campbell Harper, seconded by Mr. John Thomson, proposed Mr. Moffat as a member of the Committee. Mr. Moffat proposed Mr. Fergusson, which was seconded by Mr. Norman Thomson. Mr. Campbell Harper proposed Mr. Coltart, which was seconded by Mr. Balmain, and Mr. Balmain was proposed by Mr. Fergusson and seconded by Mr. Yerbury. There being no other nominations, the gentlemen were appointed members of the Committee. The President moved the re-election of Mr. Lowson as secretary and treasurer, which was unanimously agreed to.

Mr. Charles D. Crooke, at the end of the meeting, congratulated the Society on the great value of the work undertaken by its members, and stated that if he had known, he should have joined it long ago. He was, however, ready to do so at once, and he, along with a number of the guests, heartily accepted the invitation to join the Society.

News and Notes.

Partick Camera Club.—New headquarters of this Glasgow club have been acquired at 51a, Peel Street. The new secretary is Mr. James Whyte.

"Technology," the journal of the Manchester Municipal College of Technology, has just completed its tenth volume, which contains recent original papers by members of the staff of the College, including one by Mr. R. B. Fishenden on the use of photography in the engraving of rollers for calico printing.

Sloane Square Bargains.—Still another large list of second-hand cameras, lenses, and accessories of all descriptions reaches us from the City Sale and Exchange, this time from the branch at 26-28, King's Road, Sloane Square, London, S.W.3. It is a volume of 168 pages, and will be sent free on application to the above address.

The Adherent Tissue Co. have opened an office and showroom at 294, Regent Street, W.1 (opposite the Polytechnic), where stocks of adherent tissue, art tint papers, and apparatus for every class of dry mounting will be held, and demonstrations given. The office will be under the management of Mr. E. Cope, late of the Autotype Company.

For Cleaning Lenses.—Messrs. W. Butcher and Sons have conferred a favour on lens users by issuing, in convenient book form, the extremely soft Japanese paper tissues, which, by their complete freedom both from fluff and from any suspicion of abrasive effect, are ideal for cleaning the surfaces of lenses. The tissues are supplied, price 6d. per book, and may be obtained from all dealers.

Guilleminot Plates.—A list of the revised prices of the plates and postcards of the French firm of Guilleminot, Boesflug and Cie has been issued by the British representative, M. Jules de Gottal, 17, Cecil Mansions, Marius Road, London, S.W.17. Plates are now priced at 2s. 7d. per dozen, $3\frac{1}{4} \times 4\frac{1}{4}$; 5s. 8d., half-plate, and 10s. 11d. whole-plate. Bromide and gaslight postcards are 50s. net per 1,000, with a reduction on quantities up to 10,000. Guilleminot P.O.P. is priced at 12s. per gross of 6 × $4\frac{1}{4}$ pieces; 26s. per gross whole-plate size.

"Pictorial Composition in Photography."—The volume of this title, by Arthur Hammond, which we reviewed some months ago ("B.J.," August 27, 1920, p. 533), is now issued in this country by Messrs. B. T. Batsford, Ltd., 94, High Holborn, London, W.C.1, price 21s. net. Messrs. Batsford are also publishing here another American work which we have noticed, namely, "The Book of the Dance," by Arnold Genthe, illustrated by a large number of reproductions of photographic studies of well-known classical and other dancers. The price of this latter work is £2 2s. net.

Business in Developing and Printing.—Messrs. W. Butcher and Sons have just issued some new pieces of literature for the promotion of business in developing and printing by photographic dealers. These are a series of four distinctive lists of charges for the development of roll-films, plates and film-packs, and for the supply of prints and enlargements. The prices are the minima adopted by the Photographers Dealers' Association, affording an adequate margin of profit whether the work is done by the dealer himself or sent to a trade firm. The lists are attractively produced in a coloured cover, and each includes also particulars of a few of the most popular of Messrs. Butcher's models of hand cameras. Inclusive of the printing of a dealer's name and address on the cover they are supplied at £2 2s. 6d. per thousand; a smaller number, at a somewhat higher rate.

A General Kodak List.—The new general catalogue just issued by Messrs. Kodak, Ltd., is a handsome volume of 250 pages, which fully describes the various models of Kodak, Brownie, Premo, Graflex, and other cameras, the many specialties of Kodak manufacture, and, of course, the wide range of plates and papers manufactured at the Harrow works. While goods of Kodak origin claim a large share in these pages, the manufactures of other firms which are handled by the Kodak organisation are fully specified, so that the list is a comprehensive one of photographic supplies. One feature to be noted in respect to the general interest now being taken in the development and printing of amateurs' films is that describing the appliances—developing tanks, printers and driers—for this branch of work. The catalogue also includes a dozen pages or so of the formulæ for development, toning, etc., to be used with Kodak sensitive materials.

Raw Paper Base.—In their report for the year 1920, Messrs. Wiggins, Teape and Co. state that owing to labour and other difficulties production was not commenced during year at the new photographic base paper mill at Wooburn Green, and the new capital raised in 1919 was in consequence unproductive. The construction, however, is now almost completed, and it is hoped that production of paper will begin in the course of a few weeks.

After providing for depreciation, debenture interest and directors' remuneration, but subject to taxation, the net profits amount to £191,016, which with £3,166 brought forward makes £194,182. Interest payable to vendor companies amounts to £2,432. The directors recommend appropriating for taxation £58,000, amount written off expenses of debenture issue £5,047, dividend on ordinary shares of 5 per cent., less tax, for year, carrying forward £46,507.

In view of the uncertain outlook directors are of opinion that it is necessary to conserve company's resources, although the profits would permit payment of a larger dividend.

For 1919 net profits were £112,175. Interest to vendor company absorbed £18,604. dividend on ordinary shares was 10 per cent., and £20,000 was placed to reserve.

MEN v. WOMEN PHOTOGRAPHERS.

To the Editors.

Gentlemen,—It was to be expected that Madame Yevonde's lecture at the P.P.A. Congress would arouse some discussion, but your correspondent, "A Mere Man" ("B. J.," April 29), takes the matter much too seriously.

The "Chronicle" man naturally endeavoured to make good copy, and incidentally gave the lady a very nice advertisement. Those who were privileged to listen to the lecture entered into the spirit of fun and good humour which characterised the whole utterance.

The lady so charmingly "rubbed in" the various points she made, and accompanied the bitter she administered with such very nice sweets, that not a man felt inclined to demur, and this feeling continued in the brief following speeches by Messrs. Speaight, Adams, and Lambert.

If, however, the matter be taken seriously there is much to be said on the other side. The "Daily Chronicle" statement that photography is not a man's job is, of course, absurd, and cannot be substantiated, but some of the points in the lecture may be quite effectively countered.

Why should women have a great advantage over men in the photographing of children?

There are plenty of women doing quite good child portraiture, and more men doing it quite as well. The ability to become a maker of real pictures of children is—to quote Mr. Adams—a God-sent gift, and one that is bestowed without respect to sex. The various theories as to the quicker action of woman's brain, her greater tact in dealing with her sitters, her superior adaptability to their varying mental states would be difficult to uphold, and almost impossible of proof.

Experience shows that such mental and administrative qualities as go to make a successful portrait photographer are the possession of a gifted few, and certainly not the monopoly of either sex.

The slides shown at the close were, I think, not entirely convincing. Some of the examples were good. The bulk, however, I feel sure, did not do justice to the ladies whose work they represented.

In conclusion, may I suggest a competition which might have interesting results?

Let the P.P.A. find three subjects—man, woman, and child—each the worst procurable.

The child, fractious, ill-tempered and thoroughly spoiled; the man, one who hates being photographed; and the lady, one of those who has "been to numberless photographers and had never a good likeness yet." Send the trio round to some of the leading lady photographers, and also to an equal number of men, not more than four plates to be exposed, or half an hour to be expended on each subject. The subsequent exhibition of the untouched results and the allotting of the rewards would make an interesting feature of the next P.P.A. Congress. The male competitors should be whiskered.—Yours faithfully,

GRAHAM N. FITCHEW.

Southsea, May 2.

SOFT FOCUS WITH A SPECTACLE LENS.

To the Editors.

Gentlemen,—The article in to-day's issue entitled "The New Bergheim Lens" is of great interest, especially to amateurs like myself.

Many amateurs with pictorial ambitions are deeply interested in the numerous makes of soft-focus lenses offered for sale in the photographic journals, but very little information is available in accessible form, and many are debarred by prohibitive prices from the purchase of what is usually an unknown proposition.

In the article, reference is made to the use of uncorrected or spectacle lenses, once popular amongst photographers, and I venture to suggest that this type of lens, which, so far as soft focus is concerned, is similar in manipulation to the Bergheim lens, is likely to become once more popular amongst those amateur workers who are striving after pictorial expression.

It might be of interest if I briefly describe some recent experiments which confirm Mr. Thomas's article.

Having obtained a set of uncorrected lenses, I selected one of 20 c.m., i.e., about 8-in. focus, and fitted it to a spare lens tube with a maximum stop of 1¼-in. diameter, i.e., approximately aperture *f*/5.5.

Using this on a 3¼ × 2¼ plate, to obtain good perspective and to avoid distortion, I proceeded as follows with a portrait subject:—

Negative 1.—Orthochromatic plate exposed at visual focus. Result: Badly blurred image, due to the chromatic aberration of the lens.

Negative 2.—Ortho plate focussed to visual focus, then carefully racked towards lens until principal features became slightly blurred. The actual measurement was about ¼ in., which closely corresponds to the 1/60th mentioned in Mr. Thomas's article. Result: A clearly visible, but beautifully soft, image, retaining form and features without loss of structure.

Negative 3.—Panchromatic plate with K 2 filter exposed at visual focus. Result: A well-defined image of pleasing softness, but not so soft as Negative 2 with ortho plate.

The explanation of this is that the K 2 filter and panchro plate eliminate the violet and ultra-violet rays which form the so-called chemical as distinct from the visual focus.

Similar experiments on landscape with trees in foreground gave similar equally pleasing results.

Any degree of softness can be obtained at will on an ortho plate by regulating the amount of racking forward of plate between the limits of chemical and visual focus.

The purchase of an uncorrected or spectacle lens of a suitable focus, and an old lens tube to suit, places a cheap instrument in the hands of the amateur, with which he can obtain a pleasing variety of definition, and consequent breadth of pictorial expression.

Unlike many so-called pictorial lenses, in which the definition is regulated by the stops of the lens, this simple lens can be used at its full aperture, and any degree of softness can be obtained without altering the stop, and the single glass makes a very high-speed lens.—Yours faithfully,

HENRY N. HOLLAND.

13, Cawdor Road, Fallowfield, Manchester, May 6.

A SIMPLE SOFT-FOCUS LENS.

To the Editors.

Gentlemen,—It has occurred to me, in reading Mr. Walter Thomas's article in the "B.J." of May 6, that a soft-focus telephoto-combination which I made up some eleven years ago may be of interest to readers. Though I have not used the combination for some time, a few weeks ago I hunted out the components and re-assembled them, with a view to their use for landscape, having principally experimented in portraiture when previously using the lens.

Those who have followed the evolution of adjustable soft-focus lenses will remember those recommended by Messieurs Puyo and Pulligny, and the formulæ given for their construction, but, as Mr. Thomas points out in reference to the Dallmeyer-Bergheim lens, the character of the images obtained by their use was such as to make their appeal a somewhat limited one. The arrangement which I constructed, however, did not give excessively soft definition, and the Pulligny formulæ for their tele-anachromatic—constructed with a Petzval portrait lens of about 6- or 7-in. focus as positive, with an uncorrected negative element of about 3 in. diameter and of about two-thirds the focal length of the positive—gave a combination with which it was possible to obtain fairly long focal lengths without, of course, having to be provided with an equivalent bellows extension. My uncorrected negative lens cost but a few shillings, and I proceeded to mount it in a cardboard tube, lined with velvet, at the back of a lens panel, to the front of which the positive element was fitted, with the advantage that, being provided with a rack and pinion, one is able to adjust the separation of the elements, with, of course, a resulting variation in focal length.

The most suitable position for the negative element being ascertained for the conditions prevailing, it was found that for a large studio camera the ideal mounting was a square box of large dimensions, which hung on mirror plates inside the front panel, and allowed the usual studio shutter to work in its existing position.

There is some little difficulty at first in getting negatives of satisfactory definition where wanted, but after a few trials one soon gets used to the somewhat peculiar appearance of the image on the focussing screen. With this combination, however, there is not a large amount of variation of diffusion, except by stopping down for finer detail, and one hardly requires to do this on account of the already reduced aperture, due to magnification of the telephoto combination, but the lens still has the advantage of considerable variation in focal length, and consequently an enlargement or reduction of the size of the image without moving the camera.

To come down to practical details. I imagine there are numerous firms in the country who will produce a negative element of the required focal length, as optical glass working since 1914 has expanded very considerably here. As a guide to the selection of focal

length, I cannot do better than give an extract from my note-book which I copied down at the time for the construction of the Puyo-Pulligny tele-anachromatic, which data should apply quite well, though, as explained above, the definition will be superior by reason of the positive element being a corrected photographic lens:—

"The foci of the two lenses are in the ratio of 4 : 3, and that of the front lens F_1 is, say, 20 c.m., hence that of the back lens is 15 c.m. The actual focal length of this lens is $F = F_1 + \frac{4}{3}$ extension of camera; if the extension be 30 c.m., the focal length will be 60 c.m."

In order to obtain softer definition and greater speed in working it would be worth a trial to remove the diaphragm rings of the portrait lens entirely. F. E. HUSON.

21, Preston Road, Upper Norwood, S.E.19.

A PRINTED-OUT FILM CAMERA NEGATIVE.

To the Editors,

Gentlemen,—I enclose you a film which may interest your readers. It is from an exposure made with a V.P. Kodak at *f*/8, exposure six weeks (or more)? A local chemist put a roll into this camera, intending to take some snaps. He then forgot and left it aside, and his assistant put the camera in the window for ordinary display. (It was one of the stock cameras.) The assistant left the shutter open, and the camera was directly facing the house shown in film and print enclosed.

There it stopped for six weeks, when the chemist remembered, took it out, turned on roll to No. 2, and took his snaps. It was sent to me for development, and immediately I unrolled film I found the clear picture of house clearly printed on film (as a negative, of course), before it was even wet, and, strange to say, full development made practically no change in it. I thought, of course, it would go perfectly black!

Possibly it may be common for a picture to print out like this in such circumstances, but in ten years of developing for amateurs I never came across it before.—Your's truly, R. H. CHRISTIE.

9, Islington Avenue, Kingstown.

[The negative is dense throughout, but yields quite a presentable print.—EDS. "B. J."]

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. E.—It is our opinion that the glossy view card holds the market. We can't say why, but we certainly think it is a fact that retailers will not buy semi-matt, or rather, will not be able to sell semi-matt freely in competition with the strict glossy. For matt cards there is no doubt a certain market, but as you doubtless realise, it is not the choice of the masses.

M. T.—In no circumstances can the customer claim the negative, with the single exception of the case in which a special contract is entered into for the supply of the negative. Many photographers part with the negative for 10s. 6d., but we think the price is much too low, and that it should be at least £1 1s. We return copies of the correspondence, and, as requested, are sending "Photographic Copyright."

R. R.—With the exception of lead there is no metal that will stand long-continued action by the acid fixing bath without some protecting varnish, the best of which is the so-called anti-sulphuric paint, obtainable from dealers in electrical supplies. But we think it is best to dispense with a metal outlet on a fixing tank, or if you must have one, then you want to touch it up fairly frequently with varnish.

H. J.—Squeegeeing postcards is quite a matter of dexterity, and no great pressure is needed to expel bubbles, about two strokes with a flat squeegee being sufficient. Possibly you are hardening them too much in formaline, in which case use a weaker solution. It is necessary to squeegee right over the sink so that plenty of water goes on to the glass with the cards. Failing other remedy, you might change the brand of paper.

T. E.—(1) Nothing better than a plate of extra-rapid speed, such as the Imperial "Special Rapid." (2) Most makers supply a so-called "Press" plate giving still greater contrast than the usual brands. (3) No special paper can be said to be the best; we advise you to use the kind you are most accustomed to. (4) In our opinion nothing better than pyro-soda of the formula recommended by the makers of the plates. (5) R.R. lenses are made to give their best results with stop *f*/16.

F. J.—In the "Colour Photography" Supplement, which appears in the first issue of the "B.J." for each month, we have maintained, we think, a pretty complete record of what has been going on in colour photography, although progress has been almost at a standstill during the last five or six years. Both Dr. Smith and his "Uto" process are dead. The only book which covers the field is "Colour Photography," by Dr. Lindsay Johnson. It is a fairly good account of both theory and practice, and is reasonably up to date.

H. A.—The defect you complain of frequently occurs in tank-developed negatives, and is due to allowing the negative to remain undisturbed for too long a time. Try making two exposures of the same subject, develop one in a dish and the other in the tank, and compare results. The remedy is to move the rack up and down at least twice during development. It is not so easily detected in outdoor negatives, as when very light and dark parts come together there is usually a little halation on the shadow, and this hides the uneven development.

I. J.—The usual method of making silhouette portraits by photography is to pose the sitter in profile against a thin white sheet illuminated strongly from the other side either by daylight or artificial light. The camera is placed directly facing the side view of the sitter, and therefore also the light behind him (or her) on the other side of the background. The space between the sitter and camera requires the light to be almost completely cut off for the old style black-white silhouette, but some very excellent effects can be got by a certain amount of light on the shadow side of the sitter, sufficient to give a slight rendering of shape and details of clothes, the latter particularly in the case of women.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3185. Vol. LXVIII. FRIDAY, MAY 20, 1921. Price Fourpence.

Contents.

SUMMARY.

Mr C. Brangwin Barnes, in a short paper on the making and publishing of local view postcards, deals with a few of the factors which are often neglected by professional photographers embarking on this business in their own district. (P. 292.)

A contributor gives simple working instructions for making carriers to hold flat film of somewhat smaller size in the customary solid pattern of plate-holder. (P. 297.)

Mr. Ernest A. Dench, an American specialist in window displays, describes a few arrangements adopted by American dealers in photographic requisites for emphasising the attractions of photography as an accompaniment of anyone's holiday. (P. 291.)

Mr. J. I. Crabtree, of the Eastman Research Laboratory, has recently written a comprehensive little treatise on the causes (and preventives or remedies) of the stains which occur on negatives and prints. The first part of his paper deals with whitish and yellowish stains. (P. 294.)

The compound nature of the effect commonly described as "halation" in negatives is the subject of a leading article in which we endeavour to interpret the effect of different methods of development, which in practice are found to be of advantage in avoiding or reducing halation. (P. 290.)

At the Royal Photographic Society some time ago Mr. D. Charles reviewed the most recent improvements in methods of flashlight, and described particularly the advantages of a somewhat deep and narrow flash pan as regards obtaining a large area of flash which, therefore, needed much less diffusion than the more concentrated light produced in an open pan. (P. 298.)

For keeping specimens clean and fresh whilst in use on display in window and show case the passe-partout method of framing has obvious advantages. (P. 289.)

The oval shape of portrait is one less often seen nowadays, nevertheless, is a style which is often the most fitting for a subject. (P. 289.)

For copying-enlarging on a considerable scale, as, for example, single faces from groups, one or two small lenses should be included in the studio equipment. (P. 290.)

In making vignetting glasses it is best to use a black opaque pigment, since the effect on the print can then be better judged when preparing the vignetter. (P. 290.)

Working methods for the renovation of backgrounds are described by a contributor to "Assistants' Notes." (P. 300.)

An American correspondent, in giving some details of his experience in flashlight, asks for advice on the flashlight photography of large outdoor subjects at night. (P. 302.)

A pyro formula for black-and-white effects on self-screened plates is recommended by the writer of a letter to the Editors. (P. 302.)

EX CATHEDRA.

Passe-Partouts for Specimens.

Any method of displaying specimens which preserves their freshness, at small cost, is of interest to photographers, so that it is worth while recalling a suggestion made some time back by the late Mr. Essenhigh Corke. His idea was to make a passe-partout in which prints could be changed as required, and to do this he took the usual glass and back and bound them together at the top and sides with two mounts between, the lower edge being left open with a strip of the binding upon the face of the glass only. A thumb-hole was cut at the bottom of the backing card so that the mounts could easily be withdrawn. This method has the advantage of cheapness from the fact that all the work can be done at home and the material found in waste negatives and mounts. Narrow wooden frames have, of course, a better appearance if the cost be not objected to. If these are used they should be fitted with three-ply backs buttoned in so that no time need be lost in changing the prints. The metal Quadro frames are also effective, and when used for window display need not have the tabs glued down, the spring of the metal being quite sufficient to keep it in place if the inside is well packed up.

* * *

Oval Prints

There are fashions in photography, and prints trimmed or masked to an oval shape are now rarely seen. This is somewhat to be regretted, as this style has its merits in helping to make badly-posed figures, particularly bust portraits, presentable by cutting off the lower portion of broadened figure or an obtrusive bit of drapery. It also allows of the figure being brought into a better balanced position upon the mount than by keeping to the orthodox rectangle which in many cases would necessitate a serious reduction in size. It is quite easy to cut ovals with a swivel trimmer and zinc gauge with a little practice, although a few mishaps may occur till confidence is gained in handling the cutter. An alternative style is to use an oval mask and to cut the print square, either leaving the margins white or printing them by double printing. Effective border negatives, which give the effect of multiple mounting, may be procured from most dealers. The oval cut-out mount is now rarely seen, but for vignetted enlargements it is often very effective, an excellent effect being obtained by using a cream-toned rough-surfaced card for prints on white paper or *vice versâ*. Oval frames are again on the market, and these may often be used with advantage to vary the display in a showcase or window. Photographers in London who may have a desire to study the suitability of an oval shape to a portrait study cannot do better, perhaps, than pay a visit to the Wallace Collection simply for the sake of looking at the many Greuzes on the walls, almost all of them of this shape. We would add, too, the reminder

that when we are speaking of an oval, we mean a complete oval. We sometimes see specimens of prints or enlargements where a broken oval mask has been used and part of the subject vignetted out through the opening. We think there are very few subjects which lend themselves to this "fancy" style, which has nothing in the shape of purity of form to recommend it, and has been vulgarised very largely in the make-up of pages of portraits in the illustrated Press and in other ways. In short, if an oval is the choice, let it be an oval, and not a mixture of oval outline and vignetting.

* * *

Small Lenses. In comparatively few studios will be found any very short-focus lenses, yet these are frequently useful when it is desired to copy a small print, such as a head out of a snapshot group, or on the other hand to make a very small copy for a ring or locket from a large print. In the former case the difficulty is usually to obtain sufficient bellows extension and in the latter to avoid the flatness due to a long distance between lens and sitter. If a small hand camera with a lens of from three to five inches focal length is available it can generally be adapted to this work. If the lens and shutter cannot be detached it is not difficult to fix the entire camera with its lens *in situ* to the copying camera. It is often possible to obtain very small portrait lenses cheaply, and these are very suitable for enlarging, as their large relative aperture allows of easy focussing. We have even used the single lenses issued with the smaller Kodaks with considerable success when more elaborate instruments were not to hand for low-power photomicrography, one of three inches focal length upon a camera with an extension of a couple of feet giving a good degree of magnification.

* * *

Vignetters. Very useful vignetters may be made from waste negatives upon thick celluloid film by removing the image with a strong ferricyanide or cyanide and iodine reducer and painting the serrations and margin with opaque colour or, what is more durable, black varnish. It is not advisable to remove the gelatine coating, as the paint adheres much better to this than to the celluloid surface. Anyone who has had experience with oil colours can produce very soft gradations, which may be placed in contact with the negatives, by dabbing the colour with the finger round the opening. Such vignetters prevent the creeping of the light beyond the desired limits in the shadows of dark drapery, and also allow of closer vignetting than when all the softening depends upon the distance between the vignetter and the negative. It should be noted that a black or opaque pigment is better for making vignetters than a red or orange, as with the black the visual effect will be reproduced in the print, while with transparent non-actinic colours the light-stopping effect is greater than it appears. This was the fault of the old orange glass vignetters, which had soft graduation to the eye, but which printed with almost a sharp edge.

* * *

Portrait Proofs. There are one or two points connected with the showing of proofs which are worth the consideration of portraitists. It is a very general practice to submit untoned prints upon glossy P.O.P., an old custom which has much to recommend it. In the first place a good deal of time is saved, and in the second the gradations of the negative are faithfully rendered. The drawback is that when the finished prints are made upon bromide or gaslight paper there is often a loss at both ends of the scale of tones, giving an impression of hardness or sometimes heaviness. Care should be taken that as far as possible the proof should be printed to the same depth as the finished copies are intended to be, and, what is particular, the proofs should be trimmed to the exact size and shape which will be delivered. If more of the figure be included the composition may be spoiled, especially when oval or circular formats are finally used. If the extra cost and time is not a serious consideration there is no better way than to submit finished prints, which are counted as part of the order, if retained. These, too, often serve to supply immediate needs, and allow a little more time for completing the order.

HALATION AND DEVELOPMENT.

The volume of correspondence which has appeared in our columns during the past few weeks is a very clear indication that the drawback of halation is one which the professional all too frequently finds himself "up against." A perusal of the correspondence leads to the conclusion that benefit may be derived from a short and more or less elementary discussion of causes of the phenomenon. It may be admitted at once that our conclusions are arrived at as the result of practical trials, and that they can be accounted for by "theory" in spite of the low value attached by one correspondent to this latter element of science. Why do many of our practical professional brethren deride theory? Certainly "Experiment is the basis of Science," but we have no hesitation in affirming that many of our practical experimenters in photography would benefit enormously by the acquisition of such an amount of theoretical knowledge as would allow of the intelligent direction of their experiments and of the logical interpretation of the results of those experiments.

Let us begin by defining our subject, and in order to be the more readily understood we will call to our aid a practical experiment which many photographers must have made on the occasion of the recent eclipse of the sun. If an unbacked plate was used in snapping the partly-eclipsed sun, and assuming correct exposure to have been given at about the maximum phase, the negative will show a fairly-clear image of the crescent sun, surrounding which will be a clear space of practically fogless gelatine, this, in its turn, being surrounded by a ring or halo of deposit. It will be noticed that this outer ring is sharpest on its inner edge. If an efficiently-backed plate was used under similar conditions, the sun image will be but slightly sharper than that on the unbacked plate, but the halo will be absent. With film as the emulsion support the sun image exhibits the maximum (but not necessarily prohibitive) amount of unsharpness and only a very faint halo will be discernible at a very short distance from the true image. In the case of negatives made on thin film there will not be any clear space between the halo and the main image. Now, all these results can be theoretically explained, as will presently appear; our concern at the moment, however, is the definition of the term halation. It is generally agreed that the word may be employed to describe either the ring or halo phenomenon or the general spreading of the edge of brightly-illuminated objects. Since, perhaps, ninety-nine out of every hundred cases of halation met with are of a compound nature, there is no necessity to confine the term to one only of the two phenomena, even, although they arise from entirely different sources. The halo is caused exclusively by reflection, and has its origin in the support on which the

emulsion is coated, whereas the general spreading of the outlines of brightly-illuminated objects has, in the case of efficiently-backed plates at least, its origin exclusively in the emulsion itself, being the result of light-scatter therein. It is obvious that unless the emulsion is stained with a dye which absorbs actinic light, the more transparent the emulsion the greater will be the contribution of reflection effects towards the degradation of the image and the less will be the contribution of the scatter effects. With emulsions the gelatine of which is dyed, as is the case, for example, in screened orthochromatic plates, the reflection component of the halation is materially reduced, by reason of the fact that any light which eventually reaches the surface of the support is relatively non-actinic. Other things being equal therefore, a screened orthochromatic plate is preferable when dealing with subjects liable to give halated images. If such plates be efficiently backed, the reflection halation is reduced to its minimum, and the only degradation which can occur under normal conditions of working is that arising from scatter. This scatter may be, with some emulsions, sufficient to condemn the material; with most emulsions, however, it is a negligibly small factor.

Before turning to the influence of exposure and development, it is of interest to note that film base, largely on account of its thinness, considerably restricts the area of the reflected halation image, whilst at the same time somewhat increasing its intensity.

To understand the influence of exposure and development on halation, it is necessary to bear in mind that scatter halation spreads as the light passes into the sensitive film, whilst reflection halation spreads outwards from the bottom of the emulsion. It may be reasonably assumed that for all practical purposes it is impossible to confine the action of light during exposure to the surface of the emulsion, but it can be readily demonstrated that the minimum exposure of which the subject allows gives, *ceteris paribus*, negatives showing least halation. If we cannot confine the latent image to the surface of the film we are more fortunate when it comes to the matter of dealing with the developed image, although it is somewhat surprising what drastic steps have to be taken effectively to prevent depth development. The modern dry plate is so efficiently coated that only a thin film suffices for all general requirements—there is considerable variation in this respect amongst the various manufacturers' products—and this thin film is very rapidly penetrated by alkaline solutions, such as developers. The expedient of short development with highly-concentrated solutions is thus a delicate operation. The strength of the developer has to be such that less than a minute suffices for the operation; small time-errors under these conditions are of great importance, and in the hands of the average worker the alternative expedient of exceedingly weak developing solutions generally proves preferable. The weak solutions act by a differential "starving" of the most exposed areas, and provided they are used sufficiently dilute they allow of the development of all shadow detail before the halation image has gained prohibitive density. It will be clear that this type of development allows of great control, since five minutes' variation, one way or the other, makes no practical difference in the result. We see, therefore, that the advocates of both types of development are theoretically justified. A third method of confining development to the surface of the film depends upon the addition to the developer of such a viscous substance as glycerine or glucose, and practical trials show that this modification is remarkably efficient in depressing the development of halation. Another expedient to achieve the same object is that of developing with such an acid compound as pyro in two stages; the plate is first soaked in a plain sulphite solution of pyro for a minute or two, and then, after draining, immersed in a weak solution of sodium carbonate until the requisite density is secured.

Whichever method of development is adopted the halation is identical in amount for a given density of subject image, and in every case backed plates show marked superiority. It is, perhaps, worth noting that the Monomet sulphite developer, recently advocated by Crowther and Ermen, appears to allow of development of the true image to a greater density before the halation image is noticeable than any alkaline developer, whether the latter be employed as a highly concentrated or as an extremely dilute solution.

We have not touched upon the use of a physical developer—an acid silver solution containing metol, for example—because of the many pitfalls which its use entails, but theory indicates that experimentation with this process would be worth while, leading to images devoid of all halation.

THE HOLIDAY APPEAL IN CAMERA WINDOW DISPLAYS.

Now is the time to push cameras and supplies by trotting forth the old but ever new vacation argument. This can be presented in numerous convincing ways, if full use is made of your window display facilities

The Woodland Appeal.

The Earl V. Lewis Co., Los Angeles, Calif., U.S.A., made effective use of their window background facilities in introducing the necessary vacation time atmosphere. This took form in large framed photographs of woodland and mountain scenes, which were hung across the rear. Billows of grey velvet draped the floor, with cameras and albums placed here and there. In the middle was a trough, constructed of small cardboard boxes, over which folds of the grey velvet were draped. Planted in the trough were a row of greyish burr weeds.

Snapshotting the Family in the Garden.

The Emporium, San Francisco, Calif., were responsible for a charming garden setting, furnished with a garden bench. A woman wearing a pink afternoon dress reposed on the bench, while standing by the woman was her ten-year-old daughter in a pink dress. Over to one side father was posed in the position of photographing mother and daughter.

Favouring Her Friends

Olds, Wortman and Kings, Portland, Ore., employed wax figures to furnish a camera display with human interest. The background was a cluster of pretty pink flowers. Four figures were used in all. The first, an attractive sixteen-year-old girl, was posed at the left side in the attitude of operating a tripod camera. Her subjects at the opposite side were three much younger girls. Touches of individuality were imparted

to the figures by one of the girls with an open parasol; the second girl with her parasol closed, and the third girl with a camera case swung over her shoulder. The space elsewhere on the floor was devoted to neat arrays of cameras, tripods, albums, printing and developing sets, etc.

In the Whole Outdoors.

Woodard Clarks, Portland, Ore., conceived a window display that was very soothing to the city dweller on a warm summer day. The floor was liberally strewn with branches of trees and woodland plants and flowers over which cameras and supplies were placed. Placed between two growing palms at the rear centre was the following card:—

"The Whole Outdoors Waits for Your Camera."

On the floor in front of the yard were a bunch of snapshots of woodland and beach scenes.

Angling for Angles.

The Denver Photographic Co., Denver, Colo., made an especial appeal to anglers, whose number, of course, is legion. The centre attraction consisted of a large angler's basket, which was surrounded by several choice rods and reels. Cameras in all sizes were exhibited on the floor at each far side. On the panelled background was a six-part cartoon in the style of the comic papers. The subject matter of the cartoon visualised the enormous fish that Jones claimed he had caught. In direct contrast to this, the end picture showed the diminutive goldfish that his friends had photographed and presented to him.

Baby Out for an Airing

The Owl Drug Co., Battle Creek, Mich., caught the eye of the passer-by with a doll baby carriage, the sole occupant of which was a baby doll. These objects were being "shot" from a distance by a larger doll, with a vest pocket camera in her hands. The background was adorned with summer floral decorations.

A Window Trip to the Tropics.

The Gray Drug Co., New York City, brought the Tropics to Manhattan. The wallboard panels were painted with a white steamer cruising through a tropical inlet, with the palm-tree shores of some tropical land in the foreground of the picture. Several cardboard cut-outs of palm trees, covered with coconut fibre, with artificial palm leaves attached at the top, were "planted" in several prominent show window positions. The central location was occupied by the stump of a tree trunk, with a coloured cut-out of a lady tourist, camera in hand, seated on the trunk. Green tissue paper, shaved into tiny strips, provided the floor covering. A number of cameras and supplies were exhibited along the floor over sea-blue painted stands.

The Homelike Setting.

Ludwig Bauman & Co., New York City, have a display manager who believes in providing cameras with homelike surroundings. An excellent display of this order was made by Mr. J. Edward Rogers, an Englishman. The cream panelled background had a window effect in the centre, simulated by the hanging of a light-coloured cretonne curtain. The far left corner was occupied by a small, round wicker table, on the top of which reposed a vase of seasonable flowers, flanked on one side by a small camera, and a small portrait at the other side. Directly in front of the cretonne curtain was a large wicker rocker, with a soft cushion on the seat. A tripod camera was placed at each side. On a two-tier glass stand along the two sides—this was a corner display—were several camera models and films. A grass rug was laid on the floor at the front centre at a 45 degrees angle. Several small cameras and literature found a resting place on the rug.

For Use by the Golfer.

Bamberger's, Newark, N.J., enveloped the rear with yellowish brown draperies, with artificial grass as a floor covering. A rustic garden-seat centre held a camera, with a bag of golf sticks leaning against the seat. At each rear side near the middle a tripod camera was placed in position. Room was found at the far left side for a rustic pedestal, with a pot of trailing roses on top. This exhibit was balanced at the far right rear by a woman wax figure, becomingly clad in sports attire, with a camera strung over her shoulder. Cameras were set out on mahogany pedestals on the floor down in front.

Considering those Back Home.

March Brothers, Dexeter, Me., took a new angle of the vacation argument. A sign in their window offered the following suggestion:—

"Share Your Vacation with Those who had to Stay Home."

The centre part of the display showed a stereopticon, which was pointed toward a screen at the rear. The screen was one mass of Kodak snapshots, while groups of cameras and supplies were scattered over the purple plush-covered floor.

Ernest A. Dench.

LOCAL VIEW PUBLISHING AS A BUSINESS.

Most professional photographers seem to think that postcard publishing is too unremunerative a branch to tackle seriously, the more so as they are under the impression that what there is to be made out of it is already in the hands of one or two big firms. Hence, if they dabble in the matter at all, it is in a very perfunctory and half-hearted manner, just taking a dozen or so views of their own town and supplying prints to one or two local stationers, the net result being a pound or two extra on the takings every now and then. This work, what there is of it, is mostly done in spare time, and, in fact, the producer will tell you he only does it to fill in the gap, and that there is really nothing in it.

But once the business be embarked on in a really business and methodical manner, it will be found that the preconceived notions are erroneous, and that a really good livelihood may be made from the picture postcard business alone. One great point in its favour is that the initial outlay required is small, and that as the returns are immediate the amount of capital required is also small. Then it will be found on inquiry that the larger firms will not supply less than 500, or at the least 250, prints from each negative, whereas the average stationer does not care to stock anything like that quantity of a single subject; his usual order is for from one dozen to one gross of a subject, and rarely, if ever, for the same number of each, for while certain pictures such as, say, the famous view from Richmond Hill, will sell by the gross per week, others of perhaps the same series, while having a steady sale, will not possibly average a gross in the year. Really, it is only the multiple shop, *i.e.*, the stationer with two or more shops in the same district, or the man with a large business, who buys in quantity to redistribute to the smaller man at a slight profit, who can really deal with the larger firm of publishers.

Thus it will be seen that there is ample scope for the photographer who is ready and willing to supply the average retailer in quantities of which he can dispose in a reasonable time. For a business of this description a strip machine is all that will be required, or, as business increases, two or

three strip machines. Other necessary appliances are, of course, a good half-plate camera, with at least six double dark slides, a rapid rectilinear, a wide angle and a mid angle lens, the usual developing dishes, washing tank, etc., a supply of plates, cards, chemicals and glass for enamelling purposes. It is almost needless to add that, where sufficient capital is available, a good reflex camera is "it." Having all supplies necessary, a start should be made with a home series, that is to say, start as near home as possible. It will not be found necessary to duplicate, as used to be done when plates were comparatively cheap. A series of from twelve to twenty views of your own town to start with, then a series of the next or nearest village or small town, and so on, gradually taking in the whole of the surrounding district.

It will be found in practice that small towns and villages pay better than the larger towns, one reason being that they are not overdone, and a new series will always find a ready sale. Do not be too anxious to get to some outlying place until you have photographed all the district between you and that place; it saves trouble and money in the end to go straight on and miss nothing on the way. It must be borne in mind that the first set of orders is not going to be a very profitable affair, in consequence of the cost of plates and the time occupied in taking the views, but you must look forward to the after orders when the negatives are in stock, it is then that the real profit-making commences. It is, however, quite possible to get a bit of the initial expenses back by the sale of prints of suitable subjects to one of the illustrated papers, and anything ancient or historical is likely to command a ready acceptance, as may anything really rural, rustic, exceptionally pretty or artistic.

During the time occupied in getting together a full series of negatives there are sure to be some days either too wet or otherwise unsuitable for negative making, and then the time can be filled up by fitting up the dark-room and workroom and in preparing the negatives already in hand by titling and *varnishing*. There are numerous means of titling. The one in most general use among the larger producers is by having the whole series typed by a printer in sheets, and then producing a negative film of each sheet, from which each separate title is then cut out neatly and affixed to the film side of the negative. This method necessitates the scraping away of the negative film and the affixing of a border mark, and great care is required to ensure obtaining an even margin, as it must not be forgotten that the paper on which the print is to be produced stretches, and that only in one direction, and allowance must be made for this contingency.

The film negative, too, requires to be so accurately exposed and developed as to produce black letters on a ground sufficiently dense as not to print through. On the whole, this method is perhaps too complicated for the beginner, and one of the other systems at hand will be more probably to his liking. The German-made reversed rubber type rarely yields good results, as the letters are rarely anything like clean cut, and usually present a slovenly appearance as the gelatine film of the negative does not, as a rule, take the ink stamp at all evenly, and one or two of the letters are very apt to get out of the straight. Perhaps the best method of procedure is to print the titles direct on the negative by hand with a mapping pen and indelible Indian ink, which can be obtained at the artists' colour stores. The style of lettering should, for neatness, be small black letters, though for Christmas or Easter greetings a more ornamental style may be used. The artists' colour stores can supply a little book giving the various styles of lettering, and it is perhaps advisable to obtain such a book, so as to avoid mixing up two or more styles in one title. The tyro may think that writing a title backwards is a very difficult matter, but a little experience and perseverance will be sufficient to make it seem an easy task. Should the worker find this beyond his ability, he can get over the difficulty by printing the titles the right way round on a sheet of thin celluloid, cutting them out neatly and cementing on to the negative, lettered side down.

I strongly advocate varnishing all negatives intended for publication purposes, as there is no knowing how many thousands of prints may be in time required therefrom, and every precaution should be taken to prevent such negative from every possible chance of injury from scratches or damp. The varnish I would recommend is gum kauri, dissolved in methylated spirit, and applied in the usual manner. It will be found advisable to number the negatives consecutively throughout the whole series, one result of which will be a great saving of time when booking orders and looking out the negatives for printing. Some publishers number each town or district separately, but so doing often results in confusion, even when an initial letter is used to denote the towns. Thus, a customer might order "River view 14," or T14, or W14. As there are sure to be numerous river views numbered 14, and as T stands for Teddington as well as Twickenham, and W for Walton, Weybridge or Windsor, there would always be a chance of error in completion of order.

Each separate series should now be completed by the addition of a composite picture of from four to six of the principal subjects, and titled as "Greetings from ——," "Souvenir of——," or "Just a line from——."

The next proceeding is to obtain a good set of proofs, both black-and-white and toned, and to obtain and execute your first batch of orders. When soliciting the same, do not let any opportunity go by; let no establishment be too large or too small to call upon, and you will often find the best business accrue where you would have thought it most unlikely.

In conclusion, never buy a postcard publishing business, or you will probably find that the reason it has been sold is that the stock of negatives is years old and altogether out of date and worked out; all you really get for your purchase money being apparatus, accessories and a decaying goodwill. Once you start on a business of your own you can go on increasing it by taking in fresh towns and villages, and by adding Christmas and birthday cards.

C. Brangwin Barnes.

Sands, Hunter Lenses.—A large lens list, of 40 pages, has just been issued by Messrs. Sands, Hunter and Co., 37, Bedford Street, Strand, London, W.C.2, specifying the very large stock of objectives of all descriptions. With the object of reducing their stocks the prices of these second-hand lenses have in almost all cases been made pre-war, and further, a cash discount of 2s. in the £ will be allowed. There is evidently the opportunity for the professional photographer to add to his optical equipment on exceptionally favourable terms. The list includes scores of anastigmat portrait, R.R., and telephoto lenses as well as many objectives of the single landscape and wide angle types. Messrs. Sands, Hunter usefully list lenses in sunk mounts and in focussing mounts in sections by themselves. We can certainly recommend that the list should be obtained and studied.

Rotogravure Tissues.—The Autotype Company, 74, New Oxford Street, London, W.C.1, has just issued a booklet of notes on the rotary photogravure process, with special reference to the handling, printing and mounting of the tissue resist. The Company, as manufacturers of special tissues for this purpose, have made a thorough study of the process and are able to assist their customers in case of troubles arising from climatic and other causes. The booklet contains also a list of the tissues for gravure, including two new descriptions. In one of these, recently patented by Mr Braham, a dye is substituted for the usual solid pigment, permitting the progress of etching being more closely followed. The other is made to a special formula designed to give a resist in which the etching of the light tones will be under more perfect control.

STAINS ON NEGATIVES AND PRINTS.

[Mr. J. I. Crabtree is a member of the staff of the Eastman Research Laboratory intimately familiar with practical photographic work, and, moreover, with an aptitude for converting work of his researching colleagues which is susceptible to the process into the current coin of technique. A year or two ago we published a valuable paper by him on the making up of photographic solutions. The following article, from the "American Annual of Photography," deals in a similarly orderly and comprehensive way with the causes of stains on negatives and prints and on preventive and remedial methods.—EDS. "B.J."]

ALMOST every one of us has discovered that after storing away an apparently perfect negative, at some time later it developed an ugly brown stain, or after developing a batch of prints in the dark-room on turning up the white light the prints were seen to be stained yellow for no apparent reason. The prints were easily made over again, but the negative as far as we knew was ruined. Or we had the only existing copy of a valuable photograph which, in the course of years, had developed a stain and we wished to have several copies made but we did not know how to go about it. It is the purpose of this article to explain how and why such stains are produced, how to prevent them, and, whenever possible, how to remove them.

Broadly speaking, a stain is any deposit, foreign to the photographic image, which will absorb light, and is, therefore, capable of producing an image during printing, although in every-day language the word stain is usually associated with something coloured. A photographic stain can therefore be considered as a deposit on a photographic positive or negative whose colour is foreign to that of the photographic image. This definition would therefore include colured spots, irregular coloured markings, and general stain.

General grey stain or fog has been covered in a previous article on "Chemical Fog" ("American Annual," 1919). The matter of spots will be dealt with in a future paper so that in this article we will consider a stain as a fairly large deposit whose colour differs from that of the image, and which may be "local" (when it is not uniform) or "general," in which case it is uniform and of even density over the entire film.

For purposes of reference, stains have been classified according to their colour, and the remarks apply to all photographic sensitive materials, including films, plates, lantern slides, paper prints and motion picture film. All of these are coated with a gelatine emulsion which, after developing and fixing, consists of a layer of gelatine in which is imbedded an image of silver or one of its compounds. In the remarks below the word "film" has been used synonymously with such a gelatine silver image.

White Stains.

These may be of four kinds:—

1. *A White Powdery Scum.*—If this is removed by washing it consists of hypo crystals, and is due to insufficient washing of the film. If it is insoluble in water, and therefore not removed by washing, but is dissolved by sodium carbonate or acetic acid, it consists of aluminium sulphite. This solubility test can easily be made by placing a drop of a 10 per cent. sodium carbonate solution on the edge of the film and then washing by dipping in water. If on drying the film is clear, then the deposit is most probably aluminium sulphite providing an alum fixing bath was used.

The acid fixing bath most commonly used consists of a mixture of alum, acetic acid, sodium sulphite, and hypo, or in other words, a mixture of hypo and aluminium sulphite dissolved in acetic acid. If sodium carbonate is added to this the acid is neutralised forming sodium acetate, and as soon as the amount of acid in the bath falls below a certain critical value the aluminium sulphite comes out of the solution turning the bath milky and deposits as a white sludge, which settles on the surface of the film and is not removed in the wash water.

Since developer is carried over to the fixing bath by the film, only a definite number of plates or prints can be fixed before the critical point is reached and the precipitation of the sludge commences. At temperatures around 65 deg. F. usually a further quantity of acid hardener may be added to the fixing bath to compensate for this developer carried over, though in warm weather there is danger of sulphurisation (see below).

In order to prolong the life of the fixing bath and prevent the formation of aluminium sulphite it is therefore advisable to:

(a) Rinse the film between the developing and fixing so as to remove as much developer as possible.

(b) Use a developer containing a minimum amount of alkali.

(c) Use an acid stop bath between the developer and fixing bath. Stop baths should always be used with discretion, otherwise an excess of acid is carried over to the fixing bath which in turn causes sulphurisation.

A 2.5 per cent. solution of sodium bisulphite forms a useful stop bath, though the following hardening stop bath is to be preferred:—

	Metric	Avoirdupois
Potash chrome alum ...	15 gms.	½ oz.
Sodium bisulphite	15 gms.	½ oz.
Water to	1 litre	32 ozs.

In time this bath will deposit a sludge as a result of contamination with developer, when it should be thrown away.

If the aluminium sulphite sludge still appears after observing the above precautions, then either the acid hardener was not mixed correctly (probably too little acid was added) or the acid used was not up to strength, or too much sulphite was used.

Precipitation may take place on the print or negatives with a very alkaline developer even when the fixing bath is clear, if no stop bath is used. This is due to the fact that precipitation occurs before the developer has time to diffuse away from the film. A rinse or stop bath in such a case is absolutely essential.

In view of the solubility of aluminium sulphite in caustic soda, or sodium carbonate, the scum is easily removed by bathing the film for a few minutes in a 5 per cent. solution of sodium carbonate and washing thoroughly. If the temperature is above 65 deg. F. it is advisable to harden the film for 2 or 3 minutes in a 3 per cent. solution of formaline and then wash before the above treatment.

2. *Yellowish White Opalescence.*—This particular stain is usually visible only on negatives or transparencies, and gives the negative the appearance of having been made on opal glass or celluloid. The deposit is insoluble in water, acids, and sodium carbonate and is not removed by bleaching and redeveloping (see below). The stain consists of finely divided or colloidal sulphur and may be due to one or more of the following causes:—

(a) Too much acid or too little sulphite in the fixing bath. When acid is added to hypo sulphur is thrown down as a yellowish white precipitate, but this may be prevented by the presence of sodium sulphite which dissolves sulphur. If, therefore, the proportions of acid and sulphite are not correct in the fixing bath, or if impure sulphite is used or an excess of acid is added to the fixing bath, either directly or as a result of using a stop bath which does not contain sulphite, sulphur is gradually precipitated, and this precipitation takes place likewise in the gelatine film.

(b) The fixing bath is too warm. A correctly compounded fixing bath will keep for only a comparatively short time at temperatures above 85 deg. F. The only remedy is to renew the bath as soon as sulphurisation begins.

(c) The use of a plain alum bath either before or after fixing will often cause sulphurisation, because alum behaves like an acid towards hypo. If the alum bath must be used, the film should be washed free from hypo before treatment.

A fresh sulphur stain may be removed by immersion of the film in a warm solution of sodium sulphite. A 10 per cent. solution is satisfactory at a temperature of approximately 100 deg. to 120 deg. F. It is, of course, necessary to superharden the film by bathing for 2 or 3 minutes in a 5 per cent. solution of formaline and washing thoroughly before treatment.

3. *Silvery White Opalescence.* This peculiar stain is formed when drying negatives or transparencies by means of denatured or wood alcohol and especially if the drying is hastened by means of heat. This phenomenon has been attributed to various causes, including the use of impure alcohol, or alcohol containing rosin, insufficient fixing, or washing of the film, the presence of calcium salts in the wash water, etc., but although these factors may influence the amount of opalescence produced, they are not the determining factors, since it is possible to obtain severe opalescence by immersing a film of plain gelatine in pure grain alcohol and drying at a temperature of 95 deg. F. The amount of opalescence produced is greater the more rapid the drying and the higher the temperature of drying, but it rarely occurs even if the film is insufficiently fixed and washed if drying is conducted at 70 deg. F.

The opalescence is apparently due to precipitation of the gelatine by the alcohol to a dehydrated modification which is also produced by adding alcohol to a solution of gelatine in warm water. Hard gelatine is more readily precipitated than soft gelatine.

The precipitation is also produced by strong solutions of hypo, sodium sulphite, etc. When fixing a negative in a strong solution of hypo containing an excess of acid hardener, the fixed out film often appears milky, especially in warm weather, though the milkiness disappears in the wash water when the precipitated gelatine returns to the hydrated modification. This opalescence will often appear when removing sulphur stains with a warm solution of sodium sulphite (see above) but disappears on washing.

Immersion in water and drying at normal temperatures removes the opalescence completely. When drying with alcohol, opalescence rarely occurs if the film is thoroughly fixed, washed, immersed in a mixture of 90 vols. of alcohol and 10 vols. of water, surface dried, and then dried in a fan at a temperature not exceeding 70 deg. F.

To summarise: It is, of course, possible for two or more varieties of white stains to be present on the same film. To remove an unknown stain, therefore, the film should first of all be fixed in plain hypo, washed and bathed in a 10 per cent solution of sodium carbonate and washed to remove any aluminium sulphite. If a stain still persists this is due to sulphur, and is removed by first hardening the film for 2 or 3 minutes in a 5 per cent. solution of formaline, immersing in a 10 per cent. solution of sodium sulphite at 110 deg. to 120 deg. F. and washing.

4. *Yellowish White Stain.* The particular stain in question occurs only on old D.O.P. (gaslight) prints, the effect being a faded appearance chiefly in the high-lights where there is least silver, and the colour of the image is usually yellowish white. This stain, which develops with age, is due to the conversion of the silver image to a yellowish white modification of silver sulphide. That such a modification does exist can be shown by immersing a piece of well washed unexposed printing out paper, the emulsion of which consists essentially of silver chloride, in a 2 per cent. solution of sodium sulphide. Prolonged action of the bath produces a yellowish white image whose colour resembles that of the stain in question.

The formation of the silver sulphide may be due to either internal or external causes. Internal agents are usually insoluble thiosulphates left in the print from insufficient fixing and washing as explained above. Owing to the action of the atmosphere and moisture these thiosulphates are oxidised, and at the same time the silver image of the print is converted to silver sulphide.

If the print is fixed in a sulphurised bath which is slowly depositing sulphur, caused by too much acid in the fixing bath, or by the use of a too strongly acid stop bath (see Sulphur Stains above), the sulphur is left in the print even after washing, and this combines with the silver image to form silver sulphide. The comparative ease with which the silver image of a print is sulphurised as compared with a negative image is due to the fineness of grain of the print image.

External agents are sulphureous gases in the air such as sulphuretted hydrogen, while the hypo in the mount of a print may be decomposed and act in a manner similar to that of the thiosulphates left in the print as outlined above.

If prints are thoroughly fixed in a fresh acid fixing bath, which is perfectly clear and not depositing sulphur, and then thoroughly washed the stains may be entirely prevented.

The removal of the stains, or rather the restoration of the image to its original colour, is often a very simple matter but may also prove to be a complicated procedure.

The image of the stained print may consist of several substances, including unchanged silver, silver sulphide, possibly oxidation and silver stain (see below), undissolved thiosulphate, and possibly silver photo-halides. Usually bleaching and redeveloping, as in the case of the removal of oxidation stain (see below), will thoroughly restore the print, though in a severe case proceed as follows:

Remove all dirt from the print by dabbing with a piece of stiff dough made from wheat flour. Grease marks can be removed with benzol, or petrol, and the print finally rubbed over with alcohol. If the print is mounted, detach it from the mount by first thoroughly soaking in water, and then placing face downward on a sheet of smooth paper and tear the mount away from the print. This is important, otherwise if an attempt is made to pull the print away from the mount it will inevitably be torn. If the print is dry mounted, heat in a press and strip.

Now fix the print thoroughly in plain hypo to remove any undissolved silver halide, wash thoroughly, and then harden by bathing for 2 or 3 minutes in a 3 per cent. solution of formaline and wash. If the high-lights are stained this is due to silver stain, which should be removed in a 2 per cent. solution of potassium cyanide, removing the print as soon as the image begins to be attacked. (Cyanide is a deadly poison and should be used with great care.) Then wash thoroughly. The print should now be bleached in the permanganate bath and redeveloped as recommended for the removal of yellow stain (see below). The permanganate bath converts the image consisting of silver sulphide to silver chloride and this develops to a black silver image in the redevelopment.

Yellow Stain.

This may be of two kinds. (1) developer or oxidation stain, and (2) silver stain.

1. Developer or oxidation stain is caused by oxidation products of the developer which are transparent like a yellow dye. The stain may be either "local" or "general." Owing to the fact that printing papers are usually sensitive chiefly to blue light which is strongly absorbed by a yellow colour the stain acts as if a yellow filter were placed over the negative. Local yellow stain, therefore, causes the image on the print to be weaker in those spots where the stain is present.

General yellow stain which covers the entire film just as if the film had been uniformly dyed yellow has no harmful effect other than to increase the printing exposure.

Local Developer Stain. All developing agents, such as Elon, pyro, hydroquinone, etc., have the property of readily combining with oxygen, especially in alkaline solution, to form oxidation products which are invariably coloured yellow or dark brown, and which have the property of staining gelatine just like an aniline dye. When a developer is exposed to the air

oxidation takes place and the developer turns yellow more or less rapidly according to the temperature, the nature of the developer and the amount of surface of developer exposed.

The oxidation products, however, can in turn be reduced back again to a colourless condition by substances like sodium sulphite or bisulphite, so that if the developer contains an excess of sulphite the rate of formation of the oxidation stain is slow and usually proportional to the amount of sulphite or preservative present.

Apart from aerial oxidation, during development the developing agent is being used up, by virtue of its reducing action in changing the exposed silver salt to metallic silver, and in so doing it is oxidised itself, the product formed being usually identical with that produced by aerial oxidation. The amount of oxidation product formed in this way is, of course, proportional to the amount of silver, so that the photographic image is of a duplex nature consisting of a stain superimposed on a silver image. That such an image exists can be readily seen by immersing a pyro developed negative in Farmer's reducer, which removes the black silver image, leaving a yellow image which is composed of the oxidation product of development. The utility of this stained image is explained below.

Most developers form such a stain image, though with developers like glycin, whose oxidation product is readily decolourised by the sulphite in the developer, the stain image is very feeble.

The oxidation product, apart from being coloured, has the property of tanning gelatine, so much so that if a negative developed with, say, caustic hydroquinone, is placed in hot water, the gelatine in the clear and unhardened portions dissolves away leaving a relief image.

Local irregular shaped stains are caused by local oxidation of the developer which may be due to:

1. Careless handling of the film by incomplete immersion in the developer or fixing bath. A slight curl of the film or print, or too many films or prints in one tray, will leave some part of the surface exposed to the air, oxidation will take place and a yellow patch will appear corresponding in size to that of the portion of the emulsion exposed to the air. In motion picture work if the top of the film rack is not thoroughly submerged an oxidation yellow stain is produced which appears on the film at regular intervals. To prevent such stains it is obviously necessary to immerse the films or prints completely in the developer or fixing bath.

2. An alkaline fixing bath. Since a developer oxidises more rapidly in alkaline than in neutral or acid solution, as the acid in the fixing bath becomes neutralised by the developer carried over by the film, this developer oxidises more and more rapidly and stains the fixing or stop bath. When the fixing bath froths readily, it is probably alkaline and should be thrown away, though in some cases it is possible to renew the acidity by adding further amounts of acid hardener at intervals.

It is always important to move prints or films around in the fixing bath so that the alkali in the developer in the print is killed at once by the acid in the fixing bath. If the prints or films are simply thrown into the bath and allowed to remain at rest, the developer clings to the film and the acid in the bath is not strong enough to neutralise it completely, so that the developer oxidises and stains the film locally wherever there is an excess of developer, and especially if the film is locally exposed to the air.

An acid stop bath between developing and fixing is an almost certain cure for local developer stain (for formula see aluminium sulphite stain above). This neutralises the alkali in the developer in the film before it reaches the fixing bath, thus reducing the tendency for further oxidation.

General Developer Stain.—This exists uniformly over the entire surface of the film and is caused by:

(*a*) Old or discoloured developer or a developer containing an insufficient amount of sulphite or impure sulphite. General pyro stain is the most common on negatives.

In the case of prints, general yellow stain is produced if development is forced in a warm developer, or in a dirty tray, or if the prints are rinsed too long after developing and before fixing.

(*b*) The use of a plain alkaline fixing bath.

Developer or oxidation can be removed in two ways, (*a*) chemically, (*b*) photographically.

(*a*) If the oxidation product of the developer (oxidation stain) is treated with an acid solution of potassium permanganate it is oxidised further to a colourless substance which is soluble in water. Such an acid solution would dissolve the silver image also, but if sodium chloride is added, the bath converts the silver image to one of silver chloride while the stain is being oxidised. If the silver chloride image is now exposed to light and developed in a non-staining developer, the original silver image is restored free from stain.

To remove developer stain, therefore, proceed as follows:—

First harden the film by bathing for 2 or 3 minutes in a 5 per cent. solution of formaline and wash for 5 minutes, otherwise the gelatine is apt to soften and frill during the subsequent treatment. Then bleach in the following:—

		Metric	*Avoirdupois*
A	Potassium permanganate	5 gms.	75 grs.
	Water to	1 litre	32 ozs.
B	Sodium chloride (common salt) ...	75 gms.	2½ ozs.
	Sulphuric acid (Conc.)	15 ccs.	½ oz.
	Water to	1 litre	32 ozs.

A 5 per cent. solution of hydrochloric acid can be used instead of solution B; but as it is often of uncertain strength its use is not recommended.

The solutions A and B keep well if kept separately, but not when mixed, and for this reason the bleaching-bath should be prepared as required.

When preparing the solution A, be sure that no particles of undissolved potassium permanganate remain, for they will cause spots and blemishes in the negative.

The bleaching should be complete in about 3 or 4 minutes, when there is usually left a general brown stain all over the film due to manganese oxide, and especially in those parts previously occupied by the image. It is best to remove this stain by placing in a weak solution, say, 1 per cent. of sodium bisulphite. Then rinse and develop in a *strong light* (daylight if possible) with an ordinary developer, say Nepera solution one part, water four parts.

When removing stains by the above procedure markings caused by drying a negative without removing the drops of water (water markings) are usually removed also unless the markings are of long standing.

(*b*) Local yellow stains may be removed photographically by superimposing a deep yellow filter over the negative and making a positive from this in a printing frame on a panchromatic plate just as when making a paper print from a negative. A suitable filter is the Wratten G filter film and a suitable plate is the Wratten Panchromatic.

The panchromatic plate is sensitive to light transmitted by the G filter and in turn the G filter is of a deeper yellow than most yellow stains which are, therefore, eliminated providing the stain is completely transparent. If the stain contains any grey deposit the filter will, of course, only filter out the yellow colour from it.

An alternative method is to illuminate the negative by transmitted light as when copying or making an enlarged, reduced, or full-sized positive, and use a sheet of the filter film or a filter mounted between glass over the lens. In this case a piece of filter only slightly larger than the diameter of the lens mount is required.

Filter film consists of dyed sheets of gelatine and when not mounted between glass should be kept dry and free from finger marks.

After the positive is made it is a simple matter to make a duplicate negative on, say, Eastman. Commercial film or a Seed 23 plate in the usual way.

J. I. CRABTREE.

(To be continued.)

CARRIERS FOR FLAT FILMS IN SOLID-FORM SLIDES.

In these days of still enhanced prices for dry-plates, carriers to take a smaller size film in many cases possess advantages, and with hand-cameras usually fitted with a lens of somewhat short focus the enforced use of a smaller picture in portraiture ensures a more distant view-point, diminishing any tendency to violent drawing, the same remark applying in lesser degree to landscape work.

The Eastman flat film, now supplied in a variety of brands, offers itself advantageously for the purpose. The portrait film, despite its name, is well adapted for snapshot work, producing negatives with a fine range of soft gradation and ample density. Pinholes, due to particles of backing becoming disengaged and settling on the sensitive surface during a day's tramp, naturally are unknown, and the non-halative properties of these films enable one to face with equanimity subjects that would try a backed plate.

The fact that the films are not supplied in standard sizes smaller than 5½ × 3½ does not matter for our present purpose, as it is a simple matter to adapt postcard and half-plate films by cutting them in two, and in doing so a certain sense of satisfaction arises, partly due to the reflection on saving in cost and partly to a dim idea at the back of the head that the makers are being neatly circumvented at the same time. [Since our contributor wrote his M.S. sizes of Eastman portrait film as small as 3¼ × 2¼ in. have been issued. Eds. "B.J."]

There must still be in use a large number of 5 × 4 hand and folding cameras fitted with solid-form wooden dark slides, though this size for some time has been falling out of favour. For these, the half of a half-plate film, affording pleasing proportions, is admirably fitted. Masks on the finders, or lines on the focussing screen, will be the only alterations required to the camera.

Taking a type in which the plate is held by the rebate at the bottom and turn-buttons on top, fig. 1 shows the front of a 5 × 4 card carrier for the half of a half-plate film, which is retained by the rebate of the slide at the bottom, and by an attachment to the carrier at the top. It gives a picture size of about 4¾ × 3¼, allowing for the parts cut off top and bottom, and any ragged edges at the sides. The nick in the Eastman film, placed in invariable position to distinguish at a glance back from front, will in one of the two cut-down films be found at the side. It will also be found that the films are always cut under size, in their length sometimes very perceptibly so.

A piece of good quality millboard of suitable substance (cheap cardboard is poor economy) has black needle-paper glued on both sides, and is cut to fit the slide. On this are stuck, distant 4¼ ins. from the bottom, two very thin card strips *a a* made out of one thickness or more layers of stiff writing paper, and faced with orange paper to avoid reflection of actinic light on the bellows or walls of the camera. Orange paper is preferable to black, as easily seen when loading in the dark-room. Two further pieces *b b*, projecting from *a a* a full 3-16 in., are next attached in position shown, taking care they do not foul the path of the turn-buttons. To prevent lateral movement of the film, two strips of thicker card *c c*, equidistant from the sides of the carrier, are glued 3¼ ins. apart.

The carrier is inserted in the slide and secured; one end of the film is inserted in the bottom rebate, and the other sprung under *c c*. The space allowed (about ¾ in.) between the top strips readily admits removal of the film, without disturbing the carrier, by the insertion of a finger nail.

In the case of single metal slides, the distance between the focal plane and the travel of the shutter is too small to allow of the foregoing method of construction, and a modification becomes necessary. Fig. 2 illustrates the *back* of a quarter-plate card carrier to take half of a postcard film, affording a picture size about 3½ × 2½. An opening *d d* is cut this size, and two strips *e e* of card (no thicker than the film) are fixed, as shown, 2¼ ins. apart. On these are glued two thin strips (not shown in the diagram to avoid confusing it) of some flexible and elastic material, such as parchment paper, which

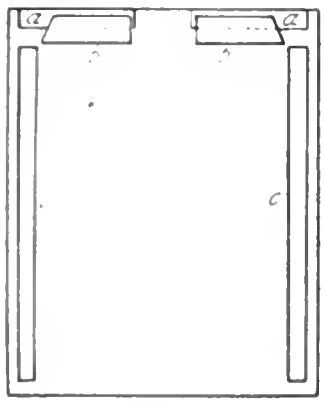

Fig. 1.

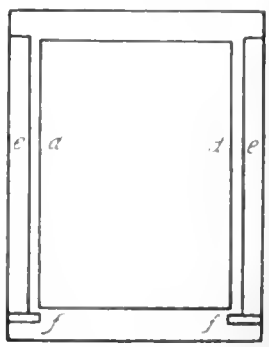

Fig. 2.

project towards the centre about ¼ in. The two pieces of card *f f* are merely stops and not strictly necessary, the film being slid in the other end. For the sake of clearness in the diagram the stops are shown clear of the lower edge of the aperture; in practice they should coincide with it. It is necessary that the fit of the film be a binding one to prevent it partially slipping out at the free end.

The carrier and held film are inserted in the metal slide in the same way as a dry plate; this results in the sensitive surface being about 1-16 in. behind the focal plane, which must be allowed for when focussing by scale. Even if the lens will not retreat beyond the infinity mark, rare are the cases when true infinity is demanded. If focussing be effected on a ground-glass screen, reversing it will be sufficient for all ordinary work.

Although such a carrier has not been tried for magazine hand-camera sheaths, doubtless it would answer well. By omitting the cut-out aperture and employing the carrier with the attached strips towards the lens, it is obviously equally well adapted for solid-form and book-form wooden slides. Apart from direct portraiture, such carriers may be of use occasionally in the studio for copying miniature prints, when half of a postcard film, or even quarter of a half-plate, can be pressed into service.

E. A. S.

ST DUNSTAN'S.—The annual report of the work of St Dunstan's and its allied institutions for the care and relief of soldiers and sailors blinded in the war, which has just been issued by Sir Arthur Pearson, shows the very successful records in the training of men for suitable technical occupations, and also the supervision which is exercised in endeavouring to enable them to make profitable use of their training as a means of livelihood. St Dunstan's still needs support by donations; it is almost pre-eminently the war-created institution which deserves to receive them.

CLIFFORD PHOTOGRAPHIC SOCIETY.—This Society has now changed its name to Forest Hill and Sydenham Photographic Society, and has appointed as secretary Mr. C. H. P. Nutter, 39, Warminster Road, South Norwood Park, London, S.E 25. Meetings are held on the first and third Monday in each month, from October to April, at Dartmouth Hall, Forest Hill.

IMPROVEMENTS IN FLASHLIGHT.

[The following paper, read before the Royal Photographic Society and now reprinted in the Society's journal, embodies much of the experience of our contributor, Mr. D. Charles, in flashlight work, and particularly in the use of a flashpan of rather narrow trough for securing a very great spread of the flash.—EDS. "B.J."]

THE possibilities of flashlight have always appealed to me very strongly. Whether one's photography is done for a living, or for pleasure, or whether one takes photographs without any ostensible reason, and merely as a habit, there are many occasions when the supply of daylight is inadequate, or even non-existent.

Packed in a few cubic inches we have here a source of actinic light suitable for any and every subject, available at a moment's notice, and really instantaneous in its action. Is there any other illuminant of which that can be said?

I propose first of all to trace the reasons why flashlight has been hitherto not so generally popular or successful as it deserves, and then to demonstrate how the difficulties have been overcome. It seems at first sight one of the simplest things in the world to set fire to a small quantity of inflammable flash-powder and allow the flare to shine upon the subject to be photographed. Many methods have been used, each of them offering certain advantages, and also some distinct disadvantages, and the difficulties of overcoming the latter have proved so troublesome that when a man has succeeded in finding a satisfactory method of ignition he feels that at last he has mastered the difficulties of flashlight work. I want to emphasise, as strongly as I can, that although satisfactory ignition has been the greatest obstacle of all, that is really only the first step to the production of really good photography. No one would suggest, for instance, that switching on an electric arc, or a few half-watt lamps, is all that is necessary to provide satisfactory lighting for making photographs, especially when the subjects are human faces.

I will ask you to bear with me while I describe various methods in general use, and while I cannot pretend that I have any epoch-making discoveries to show you, I hope to show you where the troubles really lie, and how far I have succeeded in overcoming them.

The first lamp I wish to show represents one of the earliest known flash-lamps. It consists merely of a clay pipe with some cotton-wool tied round the bowl, and a piece of rubber tube attached to the stem. While this is the crudest form of this lamp, improvements upon it are merely elaborations and are not real improvements as regards efficiency. Some plain magnesium powder is placed inside the bowl, and the wool is moistened with methylated spirit and set alight. On blowing through the tube the powder is forced through the flame and some of it is burned. Now the principal fault with this type of lamp was that the flame is far from being an instantaneous one. If one blows hard enough to make it rapid, much of the powder gets through without being burned. In any case the flame is a very small one, casting extremely sharp shadows, and plain magnesium produces a large amount of dense smoke and dust. When explosive powders were first placed on the market, the rule was to lay a quantity on a flat piece of tin, and to fire it by means of a strip of touch-paper. Now touch-paper is a very useful method of firing flash-powder provided one is not particular when the exposure is to take place, that is to say when there is nothing in the subject that is alive; but even that simple method has its own little difficulties. Touch-paper is very hygroscopic, and when damp burns feebly and jerkily, and often when the glow reaches the powder it goes out. To overcome this it should be well baked and kept in a little tin or in waxed paper, and when required for use a small strip should be folded along its length in this manner, and will then be found to burn in a much more energetic fashion.

However, most subjects that are photographed by flashlight do contain living subjects, and it was not long before it was realised that some means was desirable of firing the flash, not only at the exact moment required, but without giving the subject sufficient warning of the exposure to close eyes, or otherwise spoil the result. One of the earliest methods of achieving this was by means of a pin kept red-hot, which was released so that it should enter the heap of powder at the precise instant desired, and this remains to-day as simple and as certain as any method that exists. The lamp which I have here employs this idea, but it is intended principally for portrait work where a supply of gas is available for the Bunsen burner, and where it will become more or less a fixture. When the Bunsen is lit the pin becomes red-hot in a few seconds, and on a gentle pull being given to the cord from any point in the room the pin swings over and enters the pan through a small hole. In releasing the cord the pin swings back again into the flame, and the pan is lifted down for recharging. On replacing the pan it slips into correct alignment quite automatically. There it is, always ready for use, nothing to go wrong, and it will make portraits as well as any artificial light at a cost of about a halfpenny each for powder.

For igniting powder in the case of portable lamps paper caps have been a favourite means, and very good they are, although I understand they are rather difficult to get just now. The difficulties in their use have been two, and for those who take the precaution to keep them dry there has been only one thing against them, and that is the lack in lamps designed for firing paper caps of some provision for ensuring that the spot of explosive substance will remain where it will be struck. During the war some bright spirit discovered that a wax-vesta made a good substitute for the paper cap, but of course the same difficulty of keeping it in place was experienced, only more so. I found after some experiment that if vestas are well dried and then kept in a little tin, they are even more certain than paper caps to give a sufficient spark, but for this purpose they must receive a fairly sharp blow. A metal cap, as used in sporting guns, is now obtainable of very good quality indeed, and this is more rapid in firing than either the paper cap or the vesta, but it makes a much louder explosion. I have here a small lamp of my design made to fire with a wax-vesta. It may not be thought very pretty to look at, but it is not designed to that end. It is designed to make the photographs taken by its aid nice to look at.

The next lamp I shall show you will fire a metal cap, and by changing the small nipple for another kind will fire either a paper cap or a wax-vesta. This lamp packs into a comparatively small compass, and forms one of the handiest pieces of apparatus that a photographer can possess. I have on the table some of the experimental forms through which this lamp has passed, and I must confess to a feeling of achievement in showing you this instrument. There is a good deal more than meets the eye in a thing of this kind. For instance, take the little nipple that is used for a metal cap. A nipple as used in a shot-gun is quite unsuitable for use in firing flash-powder, and a whole series of experiments was necessary to determine the best sizes of the hole at each end as well as other points in its design; and this part, as well as other essential parts of the lamp, are made of the finest steel and hardened after making.

We now come to electrical modes of igniting flash-powder. A fuse across two terminals and fired by means of house-current is a favourite, but it has the obvious drawback that current is not available everywhere. Besides this the terminals need frequent cleaning, and the fitting of a fine fuse wire often is found a nuisance. I have also found objections raised on the part of many people to any such attachment being made to a house-supply, on account of the real or fancied risk of

blowing the main fuse, not a desirable thing where a public function is in progress. Fuses fired across dry batteries or accumulators have the disadvantage that they short-circuit the cells, which are therefore rapidly exhausted, and in that condition the fuse is very slow in getting hot and sometimes fails to ignite the powder altogether. I do not think that anyone who has used this method has stuck to it for very long. I have here a means of igniting flash-powder which has certainly been used on a very large scale for detonating dynamite in quarries, as well as for petrol ignition, namely high-tension spark, but hitherto there have been very great difficulties in getting it down to a reasonably small weight and compass for our purpose, and at the same time within a moderate cost. It is worked from accumulators or dry-cells, but absorbs very little current indeed, and requires no fuses whatever, so that a series of exposures can be made as fast as one can change plates and ladle on the powder. It also solves the problem, for the first time I believe, of firing several charges absolutely at the same moment, so that it becomes possible to arrange a series of lamps in various positions in a large building and fire them all with one pressure of a button, without the possibility of one flash going off before the remainder. The importance of this is seen if it is remembered that if there is the slightest discrepancy the first flash makes people blink, and the next photographs them in that action. As with other methods of ignition, this also has presented difficulties in adapting it for flashlight work.

Having shown, I think, that no difficulty now exists in setting fire to our flash-powder at the precise instant one wants to, I want to repeat that we have really only made the first step towards getting successful flashlight photographs. If one puts some powder on a flat tray, and fires it, by whatever means, the flare that results is about the most unsuitable as regards its shape for illuminating the subject that could be imagined. The shape of a flame obtained in this way is something like we are taught at school this earth resembles, a flattened orange, or in more scientific language an oblate spheriod. Most of the light shines straight upwards, and there is as much illuminating the surroundings as there is upon the subject, and the condensed nature of this flame is what causes the shadows often to be so harsh and dark. Of course, this is easily overcome by burning a great deal of powder so that the side of the flame shining on the subject is sufficiently large, but even if one is prepared to do this there is seldom really enough light to give adequate illumination in the shadows, and the amount of smoke produced will be very great, besides which flash-powder is not cheap enough to be thrown away in this manner. Fortunately there is a much better way out of the difficulty. You will notice that in each of the lamps I have shown you the pan is of a deep narrow section. The object of this may at first sight seem to be to prevent the powder falling about, but the real purpose is to act as a sort of guide to the explosion, and its effect it to extend the illuminating area of the flame to an extraordinary size. Some people suggest that this little front wall covers some light that might otherwise be employed in lighting the subject, but such is not really the case. An analogy is represented by firing a bullet. If one laid a bullet on a table with a little cordite behind it and ignited the latter, it is possible that the bullet might just turn over and die, but I rather doubt if it would move at all. By enclosing the explosion, and by the further interposing of thirty inches of friction, which might be thought to slow the bullet down, it actually is made to travel two miles. Perhaps I can further explain my point by showing this roughly crumpled sheet of paper, corresponding in shape to the flame produced by an open try. The effect of the deep narrow tray is to spread the flame into a flat sheet represented by a similar sheet of paper held up with its flat area towards you.

A large flame of this description has many advantages. The explosion from the centre forces the powder into such a large space that every grain of powder gets all the oxygen it wants for complete combustion, so that there is no dust from half-burned powder and all of it is used in lighting the subject. The flame at its edges is not so hot as a condensed flame, and there is really very little danger of setting fire to anything. With this shape of tray the flame is always upwards and outwards, never downwards on to the operator's hands, as is easily proved by examining a lamp that has seen a long service, the marks of the flame seldom coming more than an inch or so over the edge. Every photographer will recognise the advantages of a big light-source for getting roundness and for illuminating the shadows.

There is only one point now that I want to call your attention to in the matter of improvements, and that is in regard to very vague ideas that have been current as to the amount of flash-powder necessary for any particular job. Makers of powder have told us on their packages that so much was required for a portrait, and so much for a group, as if there were no such things as stops and plate-speeds. German manufacturers used to go a step farther by issuing tables of quantities, but these always took it for granted that one would carry a pair of scales to the scene of action and would be prepared to weigh out small quantities for each exposure. I have taken it for granted that flash-light users will employ the very fastest plates they can, and that being the case, exposures, that is to say powder quantities for average subjects, will depend entirely on two factors, namely the lens stop, and the distance of the subject from the flash. The position of the camera makes no difference unless one is taking a close-up picture such as a large head and shoulders portrait, when, of course, the usual rules come into force.

I have worked out a small table of stops and distances, but which will be found quite a reliable thing for all that, and along with it is a little ladle. This has a flat disc at each end, as it is found that a spoon is liable to retain some of the powder in it, and the idea is that if one gets as much as one can on the disc the quantity will be practically the same every time. You will notice there is one disc smaller than the other. The small ends holds just half what the large end does, and it is particularly useful in portraiture, as the quantity of powder it holds is right for the average portrait taken on an ultra-rapid plate with a lens at *f* 4.5.

Finally, a word regarding the smoke trouble may be desirable. Smoke trouble is practically a thing of the past. Provided that is that you do not want to make a long series of exposures in an unventilated room. I will just fire, to justify my statement, a couple of flashes in such a way that you will be able to notice the relative amount of smoke produced. The first will be a foot of magnesium ribbon. For a portrait with a very rapid lens and plate it would need quite three times this, so I will ask you mentally to multiply the result by three, which will give you some idea of the amount of smoke evolved by either plain magnesium or by old-fashioned flash-powders in the smallest quantity that one would ever use.

The next thing I want to show you is the amount of smoke given by a corresponding quantity of a modern high-class flash-powder. This time there will be no multiplication necessary, as the flash will be the actual quantity used for a portrait under similar conditions. If anyone wants to use flashlight as a regular studio dominant, I shall be very pleased to show him a simple and rapid way of getting rid of the smoke.

D. CHARLES.

FORTHCOMING EXHIBITIONS

April 27 to May 7. Bury Y.M.C.A. Photographic Society. Particulars from the Hon. Secretary, A. Benson Ray, 3, Agur Street, Bury, Lancs.

August 27 to September 10. Toronto Camera Club. Latest date for entries July 20. Particulars from the Hon. Secretary, J. R. Lesser, 7 Grand Street, Toronto, Canada.

A WOMAN PIONEER. According to the newspapers, there has just died at Lucy Cross Almshouses, Wells, Somerset, Mrs. Maria Budge, aged 82 years, stated to have been, with her husband, a pioneer of photography on a commercial basis in the West Country.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Renovating Backgrounds.

Now that the spring-cleaning of the studio is in most cases done, possibly the backgrounds are the only things that look a little shabby, and, as elaborately painted grounds are rarely found in a modern studio, it is not a difficult matter to put them in repair, whether stretched on frames or hung on rollers.

If on frames, tack down the canvas in any cases where it may have parted company with the frame, and if torn, a piece of old background, or other canvas, should be glued to the back, the torn edges being firmly pressed down from the front.

We will take a plain white background first. To prepare the paint, take 4 ozs. of size and boil it up with a pint of water. When the size is dissolved, take 6 ozs. of whiting and mix to a paste with a little of the size solution, finally adding the whole of the pint, and stir thoroughly. Then commandeer the ordinary household blue-bag, and give the paint a decided blue tint, remembering that it will dry considerably paler. If the blue is omitted, the paint dries a creamy tint, and will not photograph nearly so dead white. This should be applied evenly with a large distemper brush. The canvas should be first well brushed to remove all the dust.

To prepare black paint, take 5 ozs. of size and boil up with ½ pint of water. Then put ½ oz. of vegetable black into a bottle, adding ½ pint of water, and shake up vigorously. When thoroughly mixed, add to the size solution, and stir up well. Vegetable black cannot be mixed to a paste like whiting. Being so light, it merely floats on the surface of the water. A ground painted all over with this, when turned a little from the light, gives a good dead black.

By mixing the white and black, any shade can be made to match any rubbed or damaged places on painted backgrounds. As this mixture is rather deceiving while liquid, it is advisable to apply a little to a piece of old canvas and let it dry, to see the correct shade, if it is to match exactly. This mixture is also useful for renovating studio accessories, such as "stone" seats, etc.

The paint is a mixture rather than a solution, and should be stirred round with the brush every time a fresh brush full is taken, and works better if allowed to stand, with an occasional stir, for a day, or even longer.

As size sometimes varies both in strength and aroma, a little more should be used if the paint rubs off when dry, and a little turpentine will kill any objectionable smell. Prepared or concentrated size may be used; about ¼ oz. to a pint of paint.

An out-of-date, disused background can easily be converted into a new one, a soft, clouded effect being an easy matter. Unless perspective and drawing is your strong point, anything in the way of straight lines should be avoided.—R. H. F.

Enlarged Negatives.—Quite good enlarged negatives can be made either by the Kerotype method or by Kodak transferrotype. Such negatives allow of far more touching and working up than do those made on dry-plates. The cheapest method of making enlarged negatives is the old wet-collodion method, but it requires skill not often met with in modern studios.—O. P.

Reducing P.O.P.—Users of P.O.P. have often wished to save a print that has become hopelessly too dark, especially when of large dimensions, without degrading the final tone. The most successful reducer we have ever tried for the purpose is Griffin's "Parazone," used for negatives. A strong solution used after washing and before toning reduces the print so that the resulting gold tone is good and rich as usual.—M.B.

Using Desensitol.—This desensitiser may, as the instructions state, be used as a preliminary bath before development, or mixed with the developer. When using a developer containing hydroquinone, however, it is advisable to use the desensitiser as a preliminary bath, and not mixed with the developer. I find that when mixed with the developer named a precipitate is formed, and the developer is made unworkable. When the desensitiser is used as a preliminary bath, however, and the plate is rinsed afterwards, metol-hydroquinone works properly after it.—L. T. W.

Discolouration of "Matchless" Paper.—Users of the new "Matchless" sensitive paper may have discovered how very quickly the sensitive side of the paper discolours when laid in contact with cardboard, packing paper, newspaper, etc., even the placing of the sheet of instructions between two of the sensitive surfaces causing a discoloured patch. This, however, is no drawback to the paper, as the discolouration invariably disappears when the print is placed in the fixing bath and the whites are quite clean when the print is finished. One sometimes meets with the same kind of markings on matt self-toning papers, these disappearing in a like manner in the hypo bath.—L. T. W.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, April 18 to 23:—

Developing Films.—No. 11,432. Devices for holding photographic films when developing. W. Brookes.

Soft Focus Effects.—No. 11,592. Means for producing photographic soft focus effects. Hanovia Chemical and Manufacturing Co.

Film Containers.—No. 11,702. Containers for photographic, etc., films. G. Rivetta.

Film Spools.—No. 11,703. Spools for photographic, etc., films. G. Rivetta.

Containers for Exposed Plates.—No. 11,492. Containers for exposed plates, films, or cards from photographic apparatus. B. Sharp.

Developing Tank.—No. 11,319. Film-developing tank. T. H. Spencer.

Colour Photography.—No. 11,294. Colour photography. W. M. Warneuke.

Developing Tanks.—No. 11,247. Tanks for developing, fixing, etc., plates, films, etc. F. S. Witcomb.

Colour Photography.—No. 11,556. Colour photography and cinematography. E. Wolff.

Cinematography.—No. 11,165. Cinematographic projection and arrangement of cinemas. L. S. Palmer.

Cinematography.—No. 11,789. Motion-picture films. Pathé Cinéma anciens Etablissements Pathé Frères.

Cinematography.—No. 11,680. Cinematographic apparatus. J. S. Pocovi.

Cinematography.—No. 11,696. Cinematograph films. F. J. W. and P. A. Purton.

Applications, April 25 to 30:—

Optical System.—No. 12,462. Optical system for photographic cameras. S. M. Procoudine-Gorsky.

Cinematography.—No. 12,378. Cinematograph projection apparatus. C. E. Davies.

Cinematography.—No. 11,871. Cinematograph machines. H. A. Stockman.

Cinematography.—No. 11,892. Cinematography. C. H. Verity.

Colour Cinematography.—No. 12,327. Optical systems for a three-colour exposure cinematograph. Firm of C. Zeiss.

Applications, May 2 to 7:—

Trick Photography.—No. 12,883. Means for producing distorted effects in photographs, etc. C. J. Coleman.

Printing.—No. 12,903. Apparatus for printing photographic films. H. V. Lawley.

Negative Making.—No. 12,537. Production of photographic negatives. P. H. Wedmark.

Telegraphic Transmission of Photographs.—No. 12,746. Transmitting photographs, messages, etc., by telegraphy. E. W. Whiston.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

LUXOR.—No. 412,700. Photographic lenses. Taylor, Taylor and Hobson, Ltd., Stoughton Street Works, Stoughton Street, Leicester, scientific instrument makers. February 21, 1921.

AYRONA.—No. 412,797. Photographic papers. John Aeron-Thomas, Dolgoy, West Cross, Glamorgan, manufacturer. February 23, 1921.

THE AMATEUR PHOTOGRAPHER AND PHOTOGRAPHY.—(Title design.) No. B413,431. A periodical publication. Iliffe and Sons, Ltd., 19, Hertford Street, Coventry, publishers. March 15, 1921.

ZONA.—No. 413,311. Photographic papers. Thomas Illingworth and Co., Ltd., Cumberland Avenue, Park Royal, Willesden Junction, London, N.W.10, manufacturers of photographic papers. March 11, 1921.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

NEOL.—No. 408,742. Photographic developers included in Class 1. J. Hauff and Co., Gesellschaft mit beschränkter Haftung, Stuttgarter Strasse, 333, Feuerbach, near Stuttgart, Germany, chemical manufacturers.

VEDOL.—No. 411,452. Chemicals used for photographic purposes. Johnson and Sons, Manufacturing Chemists, Ltd., 23, Cross Street, Finsbury, London, E.C.2, manufacturing chemists.

TICOL.—No. 411,548. Chemical substances used in photography, photographic plates and photographic films. Thomas Illingworth and Co., Ltd., Cumberland Avenue, Park Royal, Willesden Junction, London, N.W.10, manufacturers of photographic papers.

TICOL.—No. 411,459. Photographic papers, photographic albums and photographic mounts, included in class 39. Thomas Illingworth and Co., Ltd., Cumberland Avenue, Park Royal, Willesden Junction, London, N.W.10, manufacturers of photographic papers.

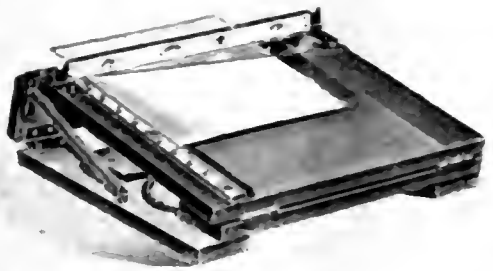
AERO.—No. 411,552. Photographic papers, photographic albums and photographic mounts included in class 39. Thomas Illingworth and Co., Ltd., Cumberland Avenue, Park Royal, Willesden Junction, London, N.W.10, manufacturers of photographic papers.

IMPEX.—No. 411,020. Photographic plates and photographic films. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W.2, manufacturers of photographic materials.

New Apparatus.

The Victo Full View Print Trimmer. Sold by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

In this new pattern of trimming desk the user is given the facility of seeing the print right up to the extreme edge of the margin which is to be trimmed away. This is done by hinging the metal straight edge under which the print is held against the knife when



the platform of the desk is pushed down for making the cut. The straight edge is very quickly released from its normally fixed position by pressing forward a projecting stud. The straight edge can then be raised, a glance taken at the margin of the print which is to be trimmed off, and then the straight edge replaced by turning it down until it is secured by a snap catch. A thin celluloid sheet, inserted between the straight edge and the surface of the desk, serves to hold the print in place whilst the straight edge is in the raised position. The trimmer thus provides a facility which at times is of distinct service, whilst it involves no disadvantage when it is not found necessary to scrutinise the whole marginal part of the print when making the cut. The trimmer is very solidly and substantially made and has a platform of 13½ × 12 inches, the effective width of the cutting edge being 12¼ inches. The desk is sent out complete with a carborundum stone for sharpening the knife.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MAY 23.

Bowes Park and Dis. Phot. Soc. "Art with a little A." J. Vacy Lyle.
Glasgow and W. of Scot. Amateur Phot. Assoc. Excursion to Aberfoyle.
South London Phot. Soc. "Photography—its Present-day Importance and Power." A. Dordan Pyke.

TUESDAY, MAY 24.

R.P.S. Scientific and Technical Group. "The Selection and Use of Illuminants for the Studio." Leon Gaster. "Illumination Problems in Cinematography." J. C. Elvey. "Methods of Light Distribution." John W. P. Walsh. "A Possible Standard of White Light." Irwin G. Priest.
Hackney Phot. Soc. Portfolios by W. Selfe and H. E. Wood.
Manchester Amateur Phot. Soc. "Pictorial Rendering of a Negative." Messrs. Carpenter, Denman, and Rothwell.
Portsmouth Camera Club. "Car-bro." C. S. Hopkins.

WEDNESDAY, MAY 25.

Croydon C.C. "Architecture with a Hand Camera." W. F. Slater.

THURSDAY, MAY 26.

Kinning Park Co-op. Soc. C.C. Open Night.
Kryn and Lahy (Letchworth) Phot., etc., Soc. 1918 Competition Prints, R.P.S.

SATURDAY, MAY 28.

Bradford Phot. Soc. Excursion to Adel.
Hammersmith (Hampshire House) Phot. Soc. Outing to the Zoo.

CROYDON CAMERA CLUB.

Last week Mr. Cavendish Morton was to have lectured on "Shaw, Shakespeare and Cæsar," and doubtless would have talked about something else in his customary manner. Unfortunately he contracted one of the many sore throats, accompanied by etceteras, which are being wafted around at the present time, and was unable to attend.

Mr. Sydney Lawler obligingly filled the gap with an interesting exposition on "Silhouettes." Beyond the fact that the finished picture can be photographed there is nothing photographic in the simple procedure. All that is necessary is to place the sitter in profile close to a sheet of cartridge paper ("Imperial" size) pinned to a board, and employ, as far off as possible, a small source of illumination, such as an arc or acetylene jet, to cast a sharp shadow on the paper. The shadow is traced round with a pencil, the paper is removed and the collar drawn in. Starting with a fine camel-hair brush, and finishing with a broad stiff one, the space is soon filled, straggling hairs being suggested at the edge with a flat hog's hair brush worked in airy fashion towards the centre. For a "black" he spoke highly of Stephens' ebony stain, mixing in the cat's saucer a little lampblack to obtain a dead matt surface. A most intense black was certainly obtained which, in the opinion of some, adequately represented the characters of the sitters. Quite an entertaining evening.

Prior to the start, the death of Mr. Friese-Greene was alluded to with expressions of regret. He was a life member of the club, and in the early nineties several demonstrations of the latest novelties were first given at Croydon by him. One of the many highly ingenious inventors who never struck oil.

Commercial & Legal Intelligence.

At the offices of the Official Receiver the first meeting of creditors was held of John Swaine, trading as Allan Swaine, 24, Elm Road, Leigh-on-Sea, photographer, against whom a receiving order was made on the debtor's own petition on April 9, 1921. He commenced business about October, 1915, with £80 capital. He purchased his business for £30, for which he obtained the remainder of a three years' tenancy agreement, studio fittings, and negatives. The landlord subsequently granted him a lease for 14 years from June, 1920, at £52 per annum, rising to £70. The business had gone down very considerably since the Armistice, and the Sheriff, who had been in possession, removed the whole of the stock, fittings, and furniture, although debtor was of the opinion that the business could have been sold as a going concern. Prior to going to Leigh-on-Sea he was employed by a firm of wine merchants at Frome, Somerset, for three or four years as under-manager and book-keeper. At the same time he carried on a photographer's business at Frome for four years doing copying, enlarging and artists' work in his spare time. He estimated his liabilities at £900 and assets £400, and attributed his present position to falling off in trade since the Armistice and lack of capital. The estate was left in the hands of the Official Receiver.

NEW COMPANIES.

Photographia, Ltd.—This private company was registered on May 7 with a capital of £5,000 in £1 shares. Objects: To acquire the business of a photographer, carried on by R. H. Townson, at 62, Cheapside, E.C., as "Photographia." The subscribers (each with one ordinary share) are: R. H. Townson, 62, Cheapside, E.C.2, photographer; F. Sharman, 26, Charing Cross Road, W.C.2, incorporated accountant. R. H. Townson is the first director. Registered office: 62, Cheapside, E.C.2.

Princess Dubarries Portrait Studios, Ltd.—This private company was registered on May 6 with a capital of £2,000 in £1 shares. Objects: To carry on the business of photographers and photographic artists, dealers in photographic goods, apparatus, chemicals and materials, etc. The first directors are: Mrs. Edith Plummer, 103, Bedford Street South, Liverpool; De Jornette Plummer, 103, Bedford Street South, Liverpool; A. Phillips, 25, Castle Street, Liverpool; R. R. MacConnal, 25, Castle Street, Liverpool. Qualification: £5. Secretary: Miss E. M. Edwards. Registered office: Grosvenor Buildings, Crescent Road, Harrogate.

Ashlee, Ltd.—This private company was registered on May 6 with a capital of £1,000 in £1 shares. Objects: To carry on the business of wholesale opticians, dealers in photographic apparatus, etc. The first directors are: J. Ashworth, Ash Bank, Riddings, near Alfreton; A. Lee, Rockmaye, Riddings, near Alfreton; H. W. Daykin, 5, King Street, Alfreton. Qualification: £1. Secretary: A. Lee. Registered office: Market Place, Riddings, Alfreton, Derbyshire.

News and Notes.

A Wigan reader, who addressed a registered letter to the City Sale and Exchange, 26-28, King's Road, London, S.W.3, without however, enclosing any name and address, is asked to communicate further with the firm.

Keeping Properties.—A correspondent in Bermuda, Mr. John J. Bushell, writes mentioning an instance in his experience of remarkably good keeping qualities of some Lumière Violet Label plates, imported by him several years before the war, and only recently exposed and developed with perfectly satisfactory results. In view of the hot damp climate of the West Indies in a large part of each year, he considers that this is an eloquent tribute to the keeping qualities of the plate. On quoting the batch number to Mr. T. K. Grant, agent for the Lumière plates in this country, we were informed that the date of manufacture was about April, 1912.

Montreal Industrial Museum.—A descriptive booklet of the commercial and industrial museum, 358, Lagauchetère Street East, Montreal, for the exhibition of native Canadian products and manufactures, and also of those of other countries which are considered of Canadian interest, is sent to us by the Director, Professor H. Laureys. The museum is attached to the Faculty of Commerce of Laval University, Montreal, and evidently aims to render service of a kind which has been organised on a very large scale by the Commercial Museums in Philadelphia. It is evident from the booklet that photographs are largely used in illustration of natural products and manufactures.

Hanging the Great Unhung.—The Great Unhung of the Royal Academy, of whom we have heard so much this year, are to be hung at the Guildhall Art Gallery in June, the exhibition opening on the 8th, and admission to be free. The event, if it is found to be a success (writes a correspondent), will no doubt revive the old-time agitation for an exhibition of the pictures rejected by the Royal Photographic Society and the London Salon. The original Photographic Salon of twenty-eight years ago was, it may be remembered, the outcome of the parent society's treatment of regular exhibitors, and the rather conservative Academy should take warning, as the Guildhall show may, if made an annual event, overshadow in course of time the proper show in Piccadilly. Anyway, the president of the Royal Academy appeare to have no fears of a serious rival, for in his letter to the Lord Mayer he says:—"I am sure that the Royal Academy would in no way regard the proposal in the nature of a criticism of any section of the Academy . . . rather welcoming it as an excellent opportunity for the public display of the works of those of established reputation who are not this year represented in the exhibition of the Royal Academy." The new show—which will remain open for four or five weeks—should be of particular interest to photographers, who, with others, will no doubt try to discover the reasons for rejection.

FLASHLIGHT: EXPERIENCE AND A REQUEST.

To the Editors.

Gentlemen,—During the summer I hope to photograph several pageants and plays which will be put on at the College. As these will all be delivered at night, and all of the dress rehearsals will be at the same time, it will be necessary to use flashlight. All of the plays will be presented in an outdoor setting among shrubbery, etc., and I am in doubt as to the proper procedure to pursue. If any of the readers of the "B J." have had experience in this line of work I would appreciate hearing of their methods through these columns, and I am sure that the editors can find room for it.

As mentioned by a speaker at the Royal Photographic Society at a recent lecture, I believe that we are farther advanced in the use of flashlight than you are. There are not a few studios in this country who are doing all of their work with flashlight, and its use among the home portraitist is almost universal. And nearly every studio keeps one for use on dark days and for children. Personally, I prefer flashlight to almost any other form of artificial light when proper apparatus for its use is to be had. My preference is for a portable cabinet into which the powder is placed from the outside without letting out any of the smoke, and which operates by friction ignition and also has a connection to operate the shutter at the same time. There are many cabinets on the market here that answer these requirements. As to the method of igniting the powder, I have finally decided, after trying several bags using different methods, that there is nothing superior to the friction method. With proper care there need never be a failure from this source, and I have made as many as two hundred flashes without a single hold up.

Using this form of apparatus there is no trouble from the smoke, since it is held within the bag. I have made as many as sixty exposures, using the same bag without emptying the bag between times. Also there was no increase in the amount of powder necessary for the last exposures because of the smoke contained within the bag.

I favour the use of the bag close to the subject. For busts I rarely use the light farther away than 3 ft. from the nearest shoulder. For three-quarters and full figures the light is farther away—about 5 to 6 ft. Due to the fact that the entire inside of the cabinet is a reflecting surface and also that the cloth acts as a diffuser, the light is very soft and even, and little powder is required. I use a mustard spoon to measure out the powder, and find that one to two level spoonfuls is sufficient. This is about three to six grains.

I have never found that children are afraid of the flash. I never mention to the child that flashlight is to be used, but go on playing with him, making my exposure by the pressure of the bulb which operates both the flash and the shutter. I often find that the flash actually amuses the child and he asks for more.

Using the connection to operate the shutter and the bulb at the same time makes it possible to work in open daylight, and all of my work is done in the ordinary light of the studio. By working in this way I have no trouble with "flashlight eyes."

I firmly believe that flashlight is the most valuable artificial light that the photographer can have at his disposal. I have found its use an economy due to the fact that no plates have been lost through movement and incorrect exposure.

While I have used flashlight constantly in the studio I have never had occasion to use it out of doors, and as there is only one opportunity for me to obtain these pictures this summer I would like to hear from any who have had experience with the use of flashlight out of doors, and feel that there must be a few others who would be interested in an account of their procedure.—Yours very truly,

CARROL B NERLETTE,
Director, Division of Photography.
Penna State College, Pa., U.S.A.

PYRO FOR BLACK AND WHITE NEGATIVES.

To the Editors.

Gentlemen,—Makers of process plates no doubt do a wise thing in advocating hydroquinone for developing negatives of black and white subjects, and in giving us no alternative formulæ, as hydroquinone is an ideal developer for the work, but I think it should be known that with suitable exposures other developers work very well with most of such plates.

I have secured good process results even with a high factor developer like Azol when hydroquinone has not been at hand. Pyro, however, is what most of us use for every-day studio work.

Recently I had some old and very much yellowed documents to copy, and for these the process plates did not come quite up to expectations, because of the plates not being sufficiently sensitive to the yellowness of the old paper and parchment.

Obviously, isochromatic plates with a yellow screen, or self-screen plates, were the things to use, and I chose the latter, but with them I met with the difficulty, as one might expect, of getting good black and white negatives of "process" quality, giving the necessary clearness in the letterpress lines and sufficient opacity to represent the yellowed base. This trouble, however, was overcome after a few experiments with a pyro-soda developer, when the following was decided upon since it gave—with suitable exposures—black and white negatives of a passable "process" quality :—

Soda sulphite (anhydrous)	160 grs.
Soda carbonate (anhydrous)	80 ,,
Potassium bromide	10 ,,
Pyro	30 ,,
Water to	10 ozs.

The pyro is added last, and just before commencing to develop. The image comes up very slowly, but gradually attains great density with clear lines. When proper density has been secured the plate (which is kept from the air as much as possible) is washed for a minute or two under water and placed in a bath of weak citric acid (30 grs. to the pint) for about five minutes, washed again for a few minutes, and then fixed as usual in a hypo-metabisulphite bath.

In theory, I suppose the 160 grs. of anhydrous sulphite named in the bath could be replaced by 320 grs. of crystal sulphite, and the 80 grs. of anhydrous carbonate by 200 grs. of carbonate crystals, but it is my experience that blacker images are always obtained with the anhydrous sodas than with the crystals. Therefore, when absolute blackness is required, it is advisable to use anhydrous sodas, particularly the sulphite.

Your readers will find the above method of working invaluable when yellowed documents are to be reproduced, especially if the negatives are printed upon gaslight paper.—Yours faithfully,

L. T. WOODS.

MADAM YEVONDE'S LECTURE.

To the Editors.

Gentlemen,—This ought to put a few "wigs on the green." Surely these ferocious whiskered individuals are not taking this lying down. According to the lady and the "Daily Chronicle," photography is not a man's job. Indeed! There have been many jobs in the profession that women could not do. In the old wet plate days I had to go seven miles with dark-room tent, silver bath, collodion, iron developer, water tank, "and all" to photograph some buildings for a law suit. Starting at 4 a.m., I arrived at 5.30 and took six 15 × 12 negatives and developed them on the spot and back again by 10 o'clock, then sensitised, albuminised paper, and printed, toned, fixed, washed and mounted them and delivered one of each by 1 o'clock, thus earning six guineas in half a-day. Could a woman have done that? I think not.

The yarn about the Knut looking like a "silly ass" reads like a joke from "The Passing Show." The removing of several chins, and slicing of waists, and ankles, does not appeal to me. I should want pure and good results in the negatives obtained in the studio.

Now I happen to wear whiskers (this by doctor's orders), and I don't look ferocious, but, on the contrary, quite genial and benign. A while ago a child was brought to the studio to sit, and the mother said to the child (pointing to me): "Who is this, baby?" The child chuckled and said "Gwanpa." I laughed, and we were at home at once, and I got good pictures. (Re mere man's letter.) I don't understand the mentality of the foremost photographer who keeps away from the children and works behind a woman. When I was in business in London one of my advertising "slogans" was "perfect pictures of children," and children were brought for miles around to "The Children's Photographer." I got pretty poses, drew out expression with a wonderful collection of mechanical toys, and got exceedingly satisfactory pictures, and "all done" in whiskers, and no lady assistant. The late John Beattie, of Clifton, Bristol, with whom I was as a youth to learn the art, was a clever thinker and writer, and an expert operator with children, and made his name famous in the West of England, and—he wore whiskers. I don't agree that women are cleverer than men with children, my long experience is *against* it.

The photographer who came back from the war, and finding his women folk had carried on during his absence still allowed them to do it, is quite characteristic of the result of the Great War. It altered men's outlook and feelings, and in many cases caused in them a distaste for work. I would advise the men to stick to it and not be cast down by this scare about photography not being a man's job, but to study it and make it their hobby, and during the slack time put their house in order and be ready for the revival of trade.

Madam Yevonde's remarks about photography languishing and nearly dying, but for women, and Miss Dora Head's remark, "It is so easy to descend to the level of the sitter," is high falutin talk. Most practical photographers (I take it) have personality, tact, patience, intuition, a quick brain; anyway, I have all these myself, plus technique in posing, lighting, developing, and artistic mounting.

I have seen some examples of the ladies' work and I should be inclined to rule as "out of court" on the principle of "handsome is that handsome does," their right to talk to us men "in that

tone of voice." To suggest that men photographers are very small beer, and that it is really surprising that we remain in the profession—"This is, I think, the limit," so I protest against this attitude. If women come into the business, they should come in with a spirit of comradeship and fair play, and not as opponents with an ardent desire to push us off the earth. Well, we are not taking our marching orders from the ladies, knowing as we do that all the progress made through all the years in our wonderful art has been achieved by men, to name a few at random, Daguorre, Niepce, Fox Talbot, Sayce, Bolton, Archer, Swan, Poitevin, Woodbury, Pouncy, Abney Muybridge and our much lamented friend Friese Greene.

Why, sir, the men have it hands down!

35 YEARS A PROFESSIONAL PHOTOGRAPHER.

LENS APERTURE AND DEPTH.

To the Editors.

Gentlemen,—In the article in your issue of May 6, 1921, entitled "Speed Limits," you state:—

"It is only very rarely that a lens with a focal-length of over 6 in. can be satisfactorily used at an aperture wider than, say, *f*/5.6."

We quite understand, from what follows, that you wish your readers to be clear that depth of focus decreases as aperture increases, but we fear the sentence we have quoted is a little misleading.

Professional photographers, who do the highest class of artistic work, would get on badly even with the fastest plates if limited to lenses with apertures not exceeding *f*/5.6. We readily admit that the larger the aperture of a lens the greater the care and skill required to use it, but such lenses, especially when fitted with diffusion adjustment, are capable of producing the most beautiful results that cannot be obtained with smaller aperture lenses or in any other way.—Yours faithfully.

per pro TAYLOR, TAYLOR AND HOBSON, LTD.,
W. B APPLETON,
Director

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

F. R.—It is legal for you to trade under a fancy name so long as you register the business with the Registrar of Business Names, 39, Russell Square, W.C.1, at the cost of 10s.

M. D.—The mask need not be in contact with the plate, but can be fixed in the back frame of the camera, as close as possible to the rear side of this frame, so as to leave the minimum distance between the mask and the plate.

G. H.—The minimum length which is possible for average work in a studio is 15 ft., but that is really too short. You can best judge of what the length should be for different classes of work from the table, p. 544 of the current "Almanac."

J. W. — We are afraid nothing can be done with a negative which has become stained in process of mercury intensification. Usually the best that can be made of such a bad job is to make the best enlargement possible and to work out the markings by hand, that is to say if they are of such a kind as to permit of this being done.

W. A.—If the reflex is a really good one and in first-rate working order you need not have any qualms about being able to make a success of your first job with it, for a reflex is one of the easiest cameras to use. We are sorry we cannot ascertain the makers of the Flora dish. We remember it, but we think it has been off the market for some years past.

T. R.—So long as the distance between the frame and the back sight is approximately equal to the equivalent focal length of the lens, it is not necessary that the frame should be vertical over the centre of the lens. Also, the only other condition for the fixing of the two parts of the finder is that the sight should lie in the horizontal line passing through the centre of the frame. Such a finder gives quite misleading results if the front frame remains fixed when the lens is raised or lowered with reference to the plate.

T. W. E.—A 2B portrait lens would require to be considerably stopped down to define a full-length cabinet, and at full aperture would have no more depth than an anastigmat of the same F number. It may be that you are working with too great a distance between the sitter and the lamps. With the *f*/5.8 Beck lens you should be able to give shorter exposures than 3 seconds. If you care to send measurements of the distance and height of lamps with relation to the position of the sitter, we might suggest some means of shortening the exposure.

S. C.—(1) As regards mercury in bromide toning, we would refer you to the report of the lecture by Mr. H. W. Bennett, which appeared in our issue of January 14 last, page 26. (2) The Watkins factor is affected by variation in the strength of the pyro, but for a given strength of pyro we do not think there is much variation in the factor by increasing or reducing to a relatively small extent the amount of the alkali. Naturally, with a lesser amount of alkali the time of development is increased, and it doesn't require much reduction to make development very much longer.

G. D.—Referring to the formula page 179 of our issue of March 25, you could certainly add more sulphite, though we do not think it would serve any useful purpose to do so, and perhaps you could use somewhat less caustic soda. The 6 ozs. and ½ oz. are, of course, by weight. Carbonate of soda can be used instead of caustic soda, but in much larger proportion. We certainly think that for the development of motion-picture film a formula made up with carbonate is better than one with caustic, especially in your hot climate, since the caustic has a softening effect on the emulsion. A very suitable formula for both negative and positive film, and one which is largely used here in the cinematograph trade, is as follows:—

Metol	3 ozs.
Hydroquinone	1 lb.
Potass. metabisulphite	2 ozs.
Citric acid	2 ozs.
Potass. bromide	½ oz.
Soda sulphite cryst.	4 lbs.
Soda carbonate cryst.	2 lbs.
Water	65 pints.

SUMMARY.

In a contributed article Mr. John H. Gear records the results of his very thorough tests of a new developing substance, or rather solution, D50, which has been worked out by British chemists. The energy, stainlessness and keeping qualities of the new preparation render it a universal developer for both negatives and prints. (P. 307.)

In a contributed article "Thermit" describes in detail a working system devised for the purpose of standardising, as far as possible, the exposures in copying various originals on different scales. The article also contains formula for a developer representing the unusual combination of pyro and amidol, and found to be of advantage in the making of copy negatives. (P. 308.)

Some elementary notes of practical application in the use of electric current for lighting and heating are contributed by "Electrician." They deal with the units in common use for the rating of electric consumption and pressure and serve to provide some guidance in the efficient use of resistances, choking coils, etc., in connection with the employment of arc and other lamps. (P. 313.)

In the further portion of his paper on stains on negatives and prints, Mr. J. I. Crabtree deals systematically with coloured stains from developers and other sources, and also with green and blue-green stains, the former most familiar as the so-called dichroic fog. (P. 310.)

In a leading article we refer to the great utility in many branches of photography of the focussing magnifier, an accessory which we believe is by no means as widely used as it deserves to be for ensuring the maximum degree of sharp focus. (P. 306.)

The twelfth exhibition of the London Salon will be held from September 10 to October 8. Last day for entries August 31. (P. 306.)

Small albums of prints of moderate size form a little speciality when the photographer can offer some good photographs of the interior and exterior of a private residence. (P. 306.)

Co-relation of mirror and focal plane shutter in a reflex camera, according to which release of the shutter is determined by the position taken up by the mirror, is the subject of a recent patent specification. (P. 315.)

Thorough cleansing of dark-room sinks is a hygienic measure of particular importance in hot weather, and can readily be done by permanganate of potash or other antiseptic. (P. 305.)

Glass which, when used as a filter, gives the visual effect of daylight with half-watt and similar lamps has its uses by the retoucher and colourist of prints. (P. 306.)

Flashlight, with or without daylight, is often the means of solving the difficulties of large groups in which young children figure. (P. 306.)

EX CATHEDRA.

The Sink in Summer. After a few hot days the dark-room sink, if not attended to, is apt to become somewhat offensive, if not actually dangerous, to health. This is due to the fact that a small quantity of gelatine, inappreciable in each negative, is dissolved and serves to make the sink and waste pipes foul and slimy. The method of cleansing depends upon the material of which the sink is made, stoneware being amenable to almost any solution from dilute hydrochloric acid to hot soap-suds, while lead or zinc-lined ones require more careful treatment. In most cases a good scrub with permanganate of potash solution, or, if this be not to hand, one of the commercial disinfectants, such as Sanitas or Milton, will remove all source of danger. When wooden grids are used they should receive specially energetic treatment and, in addition, if possible, put out of doors over the week-end. The subject may appear to be a trivial one, but as we are cognisant of several cases of throat trouble being caused or aggravated by foul sinks, it is of considerable importance. It is assumed that in all cases the sink outlet is properly trapped and that no sewer gas can escape, although in some old buildings it may not be done effectively.

* * *

The Salon. Particulars have now been published of the 12th Exhibition, arranged by members of the London Salon of Photography, which will again be held in the galleries of the Royal Society of Painters in Water Colours, 5a, Pall Mall East, London, S.W.1, from Saturday, September 10 to October 8. As in previous years entries must not be framed but may be mounted. If mounted, the mounts must be white or of light tone, and of one or other of the sizes, 15 x 12, 20 x 16 or 25 x 20. The Salon committee will themselves arrange for the display of accepted exhibits under glass. Pictures sent in by photographers outside the United Kingdom should be neither mounted or framed. The last day for the receipt of entries is Wednesday, August 31, on which day exhibits may be delivered by hand at the gallery. An entry fee of 5s. is charged and includes the cost of return postage. This fee covers any number of pictures from one exhibitor. The prospectus and entry form will be ready shortly, and will be obtainable from the Hon. Secretary of the Salon, at the address already given, but intending exhibitors, and particularly those overseas, who are unable to obtain an entry form in time, may prepare their own, provided that the usual undertaking is given to conform to the conditions of entry. The chief of these have already been mentioned; practically the only others are that a commission of 15 per cent. is charged on pictures sold at the Salon, and that the committee do not accept responsibility for loss or damage during transit or at the gallery. Exhibitors are also asked to say if they agree to their work being

reproduced in periodicals approved by the Salon committee, the usual reproduction fee being paid to the exhibitor.

* * *

At-Home Photography. There is a wide field, as yet little worked, in the photography, inside and out, of private dwellings. From time to time a photographer gets a commission to make a series of views of a house of which the owner is proud, but from the domestic or sentimental point of view very little is being done. This is probably from the idea that only large-sized pictures are to be had, and that consequently an album of one's home is a costly luxury. We have just seen an album of half-plate prints, which suggested that a very profitable side line might be created in many "select residential neighbourhoods." Man is an imitative animal (woman has also a word), and once the fashion is started it is likely to spread. Six, eight or twelve prints, according to the possibilities of the subject, in a portfolio or simple album would be a suitable arrangement. Comparatively few professional photographers touch the Autochrome or other screen-plate processes, and these might well supplement other home-pictures where paterfamilias is an enthusiastic gardener. The claims of a rose garden with its pillars and pergolas and the herbaceous border are undeniable when a good specimen is shown.

* * *

Flashlight for Babies. There are some youngsters who defy all attempts at daylight working, and for these a rapidly-burning flashlight is extremely useful, since a fully-exposed negative can be obtained in a twentieth of a second or even less. It might be feared that the flash would alarm the baby, but we are assured by an experienced worker that this is not the case. The best arrangement, and one that is common in America, is to have the lens shutter and the flash lamp operated simultaneously by electricity, in which case the exposure may be made in bright daylight, with the effect of making the flash less noticeable. Only a few grains of powder are needed for a single figure, and if a suitable flash bag be used there is no trouble with the smoke. We heard lately of a large family group with more than a dozen grandchildren in it, many of whom were very young, which was successfully secured in this way, a job at which the stoutest might quail if it had to be done indoors by daylight. "At home" child portraiture should be quite a simple matter if worked upon these lines, and the child being in familiar surroundings would probably behave better than in a strange place.

* * *

Daylight Glass. A great boon to those who have to colour or even to finish in monochrome has been introduced by Messrs. Chance Bros. under the name of "daylight glass." This, while practically colourless, corrects the light of half-watt or other metallic filament lamps to such an extent that work executed by it will stand the test of examination by daylight. For many years engravers and retouchers have used blue-tinted glasses when working by artificial light, but these are useless for coloured work. With the new glass there is a slight apparent reduction of brightness in the light, which is, of course, due to the fact that the yellow rays, which are in excess in nearly all artificial lights, except the electric arc, are intercepted, and it is these rays which are strongest in their visual qualities. Outside photography the new glass should be of great value for the illumination of picture galleries, colour printing works, drapers' shops, and in all industries in which colours have to be handled by artificial light. We have not tried the experiment, but it is possible that goggles fitted with it might answer the same purpose as screens near the source of light.

AIDS TO FOCUSSING.

THE number of photographers who go through life without using a focussing magnifier is certainly very large, and still more certainly it is larger than it ought to be. For the focussing magnifier, which is ordinarily a Ramsden telescope eyepiece mounted so that it can be adjusted to any particular vision, and clamped in that position by means of a screw collar, is a very valuable as well as simple and inexpensive piece of apparatus. For special work a more powerful instrument may be needed, and can be improvised in various ways. The possessor of an ordinary terrestrial telescope has one almost ready to his hand in the compound eyepiece, consisting of the Ramsden eyepiece, plus the erector, which can readily be converted into a focussing microscope with the half of an adapter mount. A prism monocular, with a low-power microscope objective, set in an adjustable outer tube, substituted for the object glass, makes a very efficient high-power magnifier for special purposes. But for ordinary work a magnifier which enlarges the grain of the screen to a disagreeable extent is a nuisance rather than a convenience, and for any but the specialist the magnifier of commerce, preferably of the larger size, meets all requirements.

Apart from focussing, the magnifier is a useful little tool, as it enables negatives to be examined far more critically than they can be with an ordinary single lens, and if such examinations were made more frequently a good many disappointments in regard to enlargements would be avoided, and a good many misconceptions on the subject of, more especially, marginal definition removed. Also, of course, a magnifier is essential for aerial focussing with a plain glass focussing screen, as used in photo-micrography, or with the microscope cover-glass cemented to the ordinary ground screen, which some workers in this branch and in telephotography consider a useful compromise. As a matter of fact, anyone who is called upon at times to photograph very dark interiors will find his chances of success improved if he carries an alternative plain glass screen and a focussing magnifier.

But it is more especially in everyday work with the everyday ground screen that the almost habitual employment of the magnifier is to be recommended in cases where good definition at one point or another of the picture is desired. Many people have very loose notions as to what good definition really is, and many more do not realise that their eyesight is not good enough to enable them to say with certainty that such and such a part of the image which, as seen upon the focussing screen, they imagine to be well defined, will appear really sharp in the resulting negative. Here the focussing magnifier steps in and does all that is wanted with perfect precision, and without causing any delay or trouble worth mentioning. It is, of course, necessary that the magnifier should be adjusted to the worker's eyesight and to the thickness of the focussing screen in use. But the adjustment only takes a minute or two, a pencil mark on the ground side of the screen being carefully focussed through the glass with the magnifier pressed flat against the latter, and, when the requisite degree of sharpness has been obtained, the clamping collar is tightened. The instrument then remains permanently in adjustment for that particular operator and that particular screen. To

those accustomed to use focussing magnifiers reference to this elementary procedure may seem trivial, but our impression is that of the tens of thousands of photographers who trust to the "naked eye" for focussing a large proportion are under the impression that in the proper adjustment of a magnifier some special knowledge or skill is needed.

In working with a reflex camera magnifiers fitted to work inside the hood are often of great assistance, if only for the reason that large-aperture lenses are commonly used in this connection, and focussing has to be carefully done in order to secure really satisfactory results. The point of extreme sharpness in the image produced by a high-aperture lens cannot always be easily detected in an instant by the ordinary vision, unless the latter is exceptionally good, and, when *f* 3 lenses come to be more freely used on reflex cameras, it may be taken for granted that, in spite of, or, perhaps, one might more accurately say, because of, the increased brightness of the image, the special magnifiers designed for reflex work will be more generally fitted than they are at present.

In telephotography and photomicrography the focussing magnifier can hardly be dispensed with. When the aperture is anything from *f* 1·50 to *f*/250 any and every aid to focussing is welcome, more especially as, with the sometimes rather miscellaneous optical combinations in use in such circumstances, it is almost invariably necessary to focus at the aperture at which one is actually exposing the plate. For those who cannot or will not focus aerially it is a great help to smear the ground glass of the screen with a little animal fat or with lanoline, as sold in tubes for toilet purposes.

Among aids to focussing the focussing hood or "chamber" must be noticed, and, judging from the number of high-class portable cameras fitted with these contrivances, they enjoy considerable popularity among amateurs. They cannot be said to preclude the use of a focussing magnifier, as one specially made for hooded cameras is available. But it is necessarily not so efficient as the Ramsden eyepiece type, and for all serious purposes the latter, in combination with the homely focussing cloth—as a matter of practice it is generally used without it, unless the surrounding light is overpowering—is greatly preferable. As to focussing cloths, it is somewhat late in the day to attempt suggestions for the modification of this time-honoured article of equipment. But outdoor photographers would do well to provide themselves with waterproof cloths, which are not only useful for focussing and protecting the camera on rainy days, but may also be the means of saving the operator during an interval of repose from a bad attack of rheumatism or worse. It is not a bad plan to have a focussing cloth of whatever material it is made, fitted with a few conveniently-placed little pockets, into which a stone can be slipped so as to prevent flapping in a high wind. Another elementary instruction this, but how few focussing cloths are thus provided!

A NEW DEVELOPING SOLUTION.

Many years have passed since a new photographic reducing agent has been produced, changes have been rung around the old developing solutions, and they have appeared and reappeared in slightly different form, some under a new name and a different guise, but with slight, if any, modifications in their functions. Apart from other considerations it is, therefore, interesting to find that something both novel and good has, on this occasion, been discovered upon this side of the Channel.

D.50 is the name by which the new reducing agent will be known; its name, like its functions, is quite new to the photographic community.

Dr. Seyewetz, a little more than two years ago, when reviewing the knowledge, up to that period of the chemical principle which determined the formation of synthetic developers, gave a résumé of the relations between the various reducing agents, and stated as his opinion that it is improbable that any sensational discoveries will be made of new developers of practical usefulness, since the best developing solutions as regards energy are those of the simplest constitution.

With that conclusion one would generally feel disposed to agree, but when synthetic productions are involved it is never safe to prophesy, as at any moment some great improvement may possibly be evolved and something of much greater usefulness be the result. From the latter part of 1914 to not many months ago, a great part of the sources of supply of synthetic reducing agents was materially affected, if not for a time entirely cut off. British chemists stepped into the breach and we carried on at greatly enhanced prices. English production was undoubtedly stimulated, and amongst the research work D.50 came to light; in D.50 we shall find the nearest to a universal developing solution than has been made. It is certainly capable of doing more than any other single developing solution that we have yet handled, and I think that it can justly lay claim to that wide term "universal." We are told that it is a mixture of compounds (some of which are new to chemical science) of the phenolic type, but which in consequence have never been previously used for photographic developing purposes.

It has many strong points to commend its use to photographers of all grades. I believe it will be very popular, for all those with whom I am acquainted who have used it have been most enthusiastic. I have had the opportunity, extending over a period of several months, to make a long series of measured tests and subsequently of putting it to daily tests in practical use. It undoubtedly considerably obviates the necessity for the large number of bottles usually required upon the shelves of the dark room, as the same formula answers very satisfactorily for the development of plates, bromide papers and gaslight papers, an advantage of no mean importance. That however, is not the only recommendation there is much more to favour its adoption.

It is the most economical developing solution I have handled; it can be used over and again for either plates or paper (without much loss in energy) to a far greater extent than any other I know of, there is a perfect immunity from stain on plates, papers, dishes or fingers; also, it is so very stable that I have developed with 5 ozs. of the mixed solution half a dozen plates 5½ by 3½ exposed upon interiors, the last negative being equal to the first in every respect. Its energy is greater than the majority of developers now in use, and consequently a shortened exposure is necessary. The negative is free from colour, has a long scale of gradation with great transparency, yet if desired the density of that given by pyro. can be easily produced. It does not cause chemical fog, and for that reason more than ¼ grain of potass bromide to the ounce is unnecessary; in fact, I have developed grossly under-exposed rapid plates without a trace of bromide, raising the temperature of the solution to 70 deg. Fah. with excellent results.

For portraiture it cannot fail to find favour; the reduc-

tion of exposure is an important consideration alone, but its other characteristics make it valuable for portrait work.

For bromide prints and enlargements it is equal to the best developers, and possesses other points of decided merit not found in any other single developing solution with which we are familiar.

For gaslight papers it removes the one great anxiety, viz., the liability of staining; with the papers I have used I have found that it gives a longer scale with an excellent range of tones, by direct development with a suitable exposure warm black to a true sepia colour is obtained.

I have given but a brief sketch of its characteristics, but sufficient, I think, to stimulate the interest of others to investigate for themselves.

Recently I had the pleasure of conducting some experiments upon high-speed photography in conjunction with Dr. Adolphe Abrahams, O.B.E., B.Sc., etc., and cannot do better than to give his opinion in his own words:—

"I was much interested in Mr. Gear's investigation of a new developing agent, and, at his invitation, gladly co-operated with him in examining its properties with special reference to minimum exposures, the familiar concomitant of high-speed work. The exposures, some five and twenty or so in number, varied between '1/400' sec. and '1/800' sec. Whilst a fair proportion was comparatively well exposed, at least 25 per cent. suffered intentionally from gross under-exposure. The developer was slightly modified to deal with the latter, the bromide being omitted. I was very favourably impressed with the results. The developer appears to me to combine all the advantages of an ideal reducing agent; the velocity of development is high, development is rapidly conducted, and gradation is well maintained. Hitherto I have pinned my faith to a dilute solution of pyrogallic acid in which comparatively protracted development is necessary with the corresponding disadvantages of tediousness and of the unavoidable staining of the film. But it seems to me that equally good results may be obtained by the use of this new reagent in concentrated form with a short period of development and most acceptably clean negatives. I intend to experiment at some future date with admittedly under-exposed plates, varying the temperature of the solution and the degree of concentration, although I know that Mr. Gear is all in favour of concentrated developer and comparatively brief development for such exposures. But the observations I have already made with Mr. Gear enable me to unhesitatingly acclaim it as of very high value for the type of work in which I am particularly interested."

The formula recommended is:—

A.

D.50 concentrated solution	240 minims.
Water to make	10 ozs.

B.

Sodium sulphite, cryst.	400 grains.
Sodium carbonate, cryst.	250 grains.
Potassium bromide	5 grains.
Water to make	10 ozs.

For use take equal parts.

I have found in practice that the above can be made up in one solution, and have used it repeatedly for a week quite satisfactorily, certainly there was a slight reduction in its energy towards the latter part of the week; however, with a slightly prolonged development there was no disadvantage. I took the precaution of rinsing the sodium sulphite crystals before dissolving them.

JOHN H. GEAR, Hon. F.R.P.S.

A PRACTICAL METHOD OF COPYING.

WITH many photographers the making of a copy negative is largely a matter of hit-or-miss guess work, and it is a common thing to find both photographers and customers who believe that a copy must of necessity be inferior to the original.

This is due to the fact that often no system, either scientific or practical, is used in copying. In workshops and studios where such system is adopted it is generally possible to obtain results quite equal, and often superior, to the originals. In my experience I have known only two places where a system was practised; one of these systems I worked out some two years ago, and having proved its use I propose to describe it for the benefit of practical workers who may be attracted by the possibilities of a simple method of dealing with batches of mixed copying.

The principal considerations are the camera, the lens, the easel, the plate or film, and the light. Almost any camera with a fair extension will serve for copying, but the types that are specially built for this work offer many advantages. A copying camera need not, however, be built by a camera maker, the adaptation of a strong field camera being quite within the power of the average photographic handy man. The main thing is a rigid, level board of 5 or 6-feet length, ribbed on the underside to prevent warping with time and use. Cleats or grooves are required on the top to enable the camera to slide along in a straight line and to keep it permanently at right angles to the easel. Swing back, rising front and swing front are very seldom of use in copying, and can be readily dispensed with to simplify matters. If they are retained the movable parts should be marked at the normal positions, so that errors due to want of squareness or perpendicularity in the camera do not occur.

Anastigmats are the best lenses for all-round copying. There is no ideal focal length for general use, though 6, 7, or 8-inch will be found to cover most work comfortably. I have used for some time a Cooke of 8-inches, supplemented by a wide angle lens of 4½, and I find that on a 6-feet board I can cope with a very large variety of work, including the reduction of 3-feet drawings to lantern slides. With wide angle lenses there is a risk of illuminating more than the plate, the extraneous light being reflected from the bellows and causing fog. This can easily be prevented, however, by the use of a mask in front of the lens.

The easel is best built to the base board, and, if made in two parts, much trouble in squaring up and centering will be avoided. The easel stand can be formed of a piece of thick plank, slotted half-way down its length, and fixed firmly at one end of the base board. The easel board must be smooth and flat. A drawing board answers well for this purpose. A bolt is put through the centre and the head sunk level with the surface of the board. A large washer and nut on the bolt will allow the board to be clamped in any position on the easel stand, and if a wing nut can be obtained, raising, lowering and tilting are very rapidly done. The bolt should be firmly fixed in the board to prevent turning, and eventually wearing through. A coat of dead black will improve the board photographically.

Some studios use the same plate for copying as is stocked for portraiture. Others stock a very slow plate specially for copying work. Neither of these methods is ideal. Copies vary like amateur negatives, and no one would print an assortment of negatives all on one grade of paper if the best results were required. To obtain a rich negative on a fast plate,

and from a flat copy, is next to impossible, and to obtain a soft result on a slow plate and from a chalky picture is no easier. Eastman Process Film is the only medium I know which can attempt these tricks with any measure of success. I am speaking from a busy, practical standpoint, and exclude experimental calculations, which enable much to be done that cannot be accomplished with certainty in practice. I find that an "ordinary" plate, a rapid plate, and Eastman Films, Commercial and Process, cover everything. The plates are chosen with a view to avoiding halation, a fault which is more prominent with some makes than others. Film negatives are preferred by certain customers, and are no different to work.

After trying various schemes of lighting, I consider the four-lamp frame which is supplied with some copying outfits is the most serviceable for the average copy. Roughly described, this is a square box placed on the base board with the open side facing the easel. A 20 or 40 c.p. lamp is fitted in each corner and the inside is painted white. The bottom or back of the box is cut away and fitted with negative carriers from whole plate down. With all carriers removed the opening is about 10 inches square.

The camera slide must obviously be large enough for the largest negative that is likely to be made, therefore carriers will be in use for other work. These should fit exactly, and if they cannot be made to do so a rule should be put in force by which the carriers are always kept to one corner, and the guide lines on the focussing screen must be arranged to tally with the set positions of the carriers. The value of this will be felt when copying a picture that is detailed up to its edges and it is required to fill the plate exactly.

I find it is a good plan to divide copies into four classes—normal, darks and sepias, very darks, dark sepias and reds, and light. The depth and colour of the copy are factors to be considered in calculating the exposure, of which more anon. I start a batch with a normal print, and one that is required same size, if possible. Failing this, I take the nearest to this type. Having pinned it to the board—I use haberdashers' "berry" pins in preference for this job, though there is no reason why any other effective way of fixing up the copies should not be used—by the extreme corners, or, if on a fancy mount, by strips of black paper across the ends of the mount. Pinning the paper ends to the board only, I size and focus up, and then consider if there is any necessity to vignette either in part or all around. Many defects can be hidden by vignetting. It is done by fixing white tissue or typing paper across the aperture in the light box. The depth of the vignette can be adjusted by reflecting light on to the side farthest from the lens from pieces of white mount placed leaning against the easel at each side of the copy. The correct effect is judged on the focussing screen. If no vignetting is required I close down the aperture in the light box with carriers until little more than the copy is visible on the screen. If no outside light is allowed to play on the light box, no light but that forming the image will reach the plate, and a clean result should be certain.

The exposing of a copy negative is not so simple as many think, if it is desired to give a correct rather than a hit-and-miss exposure. It consists of rather more than taking off and replacing the lens cap. At the same time, to expose a batch of mixed copies correctly without wasting plates or having recourse to continuous tests is not so impossible as I have heard it declared to be by more than one. Exposure here, as elsewhere, is governed by certain factors, viz., the reflecting power of the copy, the light-intensity, the stop, and the plate speed. If we knew all these the rest would be plain arithmetic, but they cannot be reduced to constant values, and an unpleasant amount of mathematical work would be entailed were we to examine them all each time we exposed. To get over this I have evolved a plan by which exposures can be found for widely varying copies in less time than it takes to make tests. I do, however, develop the first negative of a batch, as it is possible in photography for a factor that is correct for yesterday to be wrong to-morrow. Municipal electric current, for example, is not always at the same pressure, though civic authorities may differ on the point. For my purpose, though, I consider the light as a constant, and also the lens aperture, which I keep fixed. (One point less than full aperture is quite all right with any good anastigmat.) Changes in value, due to changing bellows extension, are covered by a simple factor, which at the same time allows for change in intensity of light due to changed distance of camera from copy. The exposures are calculated from a standard one, which must first be decided by experiment. This standard may fluctuate with new batches of plates and ageing lamps. It is the exposure necessary to get the best possible negative from a good average black and white print on a rapid plate, the copy being the same size as the original. The formula for copies not answering to the standard description is: $SE \times \frac{FL}{SFL} \times CC \times G$, where SE is the standard exposure, FL the focal length, SFL the standard focal length (twice the ordinary or principal focal length of the lens), CC the class of copy, and G the grade of plate. The result of the expression is multiplied in the case of larger than same size copies by 5/3, and, when reducing, by 3/5. In other words, when FL is greater than SFL, multiply by 5/3, and when SFL is the greater multiply by 3/5. The classes of copies are valued as follows:—Light, 2/3; normal, 1; dark, 1½; very dark, 2. The ordinary plates, the commercial film and the rapid plates are as 2, 1½, and 1 in relative slowness.

An actual example will explain the working of the system better. Three negatives were required from a small print, one same size, one to fill a half-plate, and one for a locket. As the print was a normal one, and an ordinary plate was to be used, the exposure was twice the standard. The SE at the time was 30 secs., so 1 minute was given. The formula for the second negative was $30 \times \frac{FL}{SFL} \times \frac{1}{1} \times \frac{2}{1} \times$ by the factorial fraction. The lens being an 8-inch one, SFL was 16 and FL in this case was 22, therefore we get $30 \times \frac{22}{16} \times \frac{1}{1} \times 2 \times \frac{5}{3}$, which equals 177 secs. This exposure was given. The third case gave the formula $30 \times \frac{9}{16} \times \frac{1}{1} \times 2 \times \frac{3}{5}$ which equals 20 secs. (ignoring fractions). This exposure was given, and the three plates were tanked for the same length of time together. The resulting negatives were identical in density and printing quality.

I should say here that the factors $\frac{5}{3}$ and $\frac{3}{5}$ are purely empirical, and for FL's of only slight disparity with the SFL they are high. When the difference between the FL and the SFL is not more than 1 in 12, a factor of $\frac{5}{4}$ or $\frac{4}{5}$ will give a more accurate result.

In recording the focal length, no great accuracy is necessary. If we rack out the bellows sufficiently to focus a copy same size, a distance equal to twice the principal focal length can be marked on the front and back panels of the camera, and all future measurements can be taken from the two marks. In the case of a projecting lens, or one having its node in front, a sufficient distance will not be obtainable between the panels of the camera. This can be got over by fixing a small slip of thin wood to the side of the front in such a way that it projects out forwards. The front mark can be made on this slip.

Special calculations for changing light-intensity are not necessary if the light-box is used in a fixed position with regard to the easel. With large copies which necessitate a new position for the light-box, in order to get even illumination, a new standard exposure must be found. Orthochromatic and panchromatic plates used with screens are best treated as individual cases unless a number of similar originals are

being copied with the same screen and platee, in which case, provided the standard exposure for such screen and plate is known, the system can be used with confidence.

Any developer and any development system that is understood can be used for copy negatives. In fact, this class of negative is about the easiest to develop. I have recently been experimenting with a compound of amidol and pyro, which I find gives all the advantages of both agents, and is exceptionally good for avoiding empty or clogged negatives if development is done by junior assistants. Negatives developed with this mixture are invariably of very good printing quality, even if deliberately under- or over-exposed. I have been unable so far to find a way of compounding the formula easily or so that it will keep. For those who are interested, I give below the best formula I have so far obtained. This will keep for a few days, but loses speed with age. The factor is, however, the same while the solution is good. For dish work the developer can be used repeatedly, without any difference being noticed in the quality of succeeding negatives. The formula is:—

Water	20 ozs.
Potass metabisulphate	10 grs.
Soda sulphite	1 oz. 6 drs.
Amidol	50 grs.
Pyro	20 grs.
Potass bromide	10 grs.
Water	10 ozs.
Soda hydrate...	10 grs.
Water to 40 ozs.	

When the first solution is made the caustic is dissolved separately, and the solution added slowly to the first. Both solutions should be quite clear before mixing. Any discolouration in either appears to indicate instability; the greater the discolouration the quicker the developer goes off. I find that with the undiluted solution, at 65 deg. F., development of 4 minutes is correct for most plates. THERMIT.

STAINS ON NEGATIVES AND PRINTS.

(*Concluded from page* 296.)

It is possible to remove almost any coloured stain from a negative or print in a similar manner by a suitable choice of filters provided the stain in question is not muddy as if it were mixed with a black medium. It is simply necessary to choose a filter such that on viewing the stain through the filter, the stain becomes invisible. Thus, a red filler should be used for a red stain and so on, taking care to use a panchromatic plate, which is sensitive to all colours. In the case of a blue black ink stain a blue filter will cut out only the blue. It is better to remove such stains by chemical means.

Although most photographic stains are objectionable, a developer stain image which is formed *in situ* along with the silver image during development, as explained above, is often of great value because it is capable of producing a print just in the same way that a print is produced by a silver image. Photographic papers are usually sensitive to blue light only which is strongly absorbed by a yellow stain, which therefore behaves photographically like a black image. Figs. 1 and 2 illustrate this point. Fig. 1 is a print from a pyro-stained negative. This negative was then placed in Farmer's reducer until all the silver was removed leaving a yellow stain image. Fig. 2 is a copy of a print made from this stain.

Of course, pyro is not the only develeper which will give a stain image. Developers such as hydroquinone, or oxyisocarbostyril, give warm brown and reddish oxidation products, and these can be utilized in obtaining warm tones by direct development.

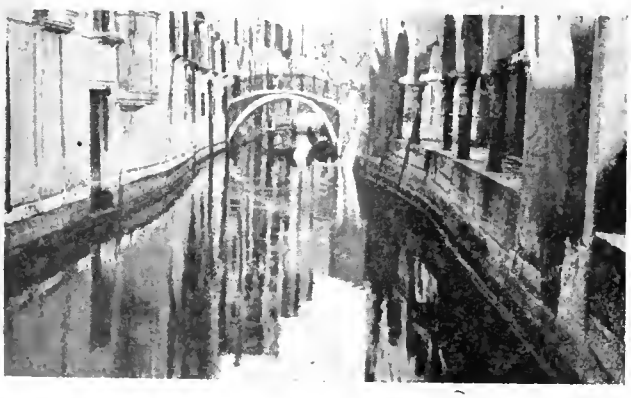

Fig. 1.

The oxidation products of a developer like monomethyl paramidophenol sulphate (Elon) are powerful fogging agents so that if it is attempted to produce a stain image with such a developer se much general fog, and therefore general stain, is formed that the stain image is entirely hidden.

Fig. 2.

The printing value of a stain image explains why an apparently weak-looking pyro negative will give good prints on a soft printing paper. This is because the stain which appears transparent and weak to the eye is really opaque photographically.

So far as it has been possible to determine, a pyro stain image merely intensifies the black silver image and does not otherwise alter the photographic quality, so that usually the same result in printing can be obtained by prolonging development of the negative, which result can also be attained by intensification.

The question is often asked, therefore, as to whether it is better to develop for a longer time in a non-staining developer like metol hydroquinone or for a shorter time in a staining pyro developer. If it is desirable to always duplicate results as in the case of developing motion picture film in a deep tank, a non-staining developer is desirable, because under these conditions it is impossible to duplicate results with a staining developer as explained below.

It is practically impossible to obtain a stain image which is free from general stain and *vice versâ*. The proportion of general stain to image stain depends on the following factors:—

1. The quantity of sulphite or preservative in the developer,

The greater the quantity of sulphite present, the less is the stain produced and *vice versâ*.

If the developer is old it rapidly becomes highly coloured and then produces general stain with little or no silver or stain image, because the developer has been largely converted to oxidation products which will not develop an image.

2. The time of rinsing between developing and fixing. A long rinse permits further oxidation of the developer by the oxygen dissolved in the wash water and this produces general stain.

3. The nature of the fixing bath. Since sulphite or bisulphite bleaches out stain and prevents oxidation of the developer, an acid fixing bath, therefore, destroys both general stain and the stain image. Hence, in order to produce the maximum amount of stain image, use a fresh developer, rinse quickly between developing and fixing, and fix in a large volume of fresh hypo.

The following pyro formula when used fresh will give a good stain image with a minimum of general stain :—

	Metric.	*Avoirdupois.*
Pyro	5 gms.	75 grs.
Sodium sulphite	2.5 gms.	40 grs.
Sodium carbonate	10 gms.	150 grs.
Water to	2 litres	64 ozs.

Develop for 6 minutes at 65 deg. F., rinse and fix in a plain hypo bath.

The above reasons explain why it is impossible to produce pyro stain with precision on a practical scale such as in deep tank work. As the developer becomes older the proportion of oxidation stain to stain image changes, which in turn changes the quality of the negative.

If a negative is stained too strongly, the stain may be reduced by first removing it entirely by bleaching in a permanganate-chloride bath as above, and instead of developing in a non-staining developer use a mildly staining pyro developer. This procedure usually gives more general stain, however, in proportion to the stain image than if the original emulsion had been developed with the staining developer in the first place.

2. *Yellow Silver Stain.*—Another form of yellow stain is due to compounds of silver left in the film after fixing and washing. It is difficult to distinguish silver stain from oxidation stain by ordinary observation, though it is usually less transparent and is more of a dirty yellow colour. Like oxidation stain it can be either local or general and may be due to one or more of the following causes :—

1. The use of an old and exhausted fixing bath containing an excess of silver in solution so that if the film is no sufficiently washed, some of the silver salt remains after drying. This compound is colourless, but is gradually changed to yellow silver sulphide on exposure to the air. To prevent such stains, therefore, it is important to use only fresh acid fixing solution.

2. Incomplete Fixing.—This can occur with a new fixing bath, if the print or film is removed from the fixing bath too soon. While the film is fixing, the silver halide in the emulsion changes first to a colourless silver thiosulphate (hypo is sodium thiosulphate) which is not readily soluble, and at this point the milkiness of the emulsion disappears. Further action of the fixing bath converts this difficulty soluble compound to a more soluble double thiosulphate of silver and sodium, which is readily washed out of the gelatine film. If, therefore, the film is removed from the fixing bath as soon as the milkiness has disappeared, which is the first stage of fixing, prolonged washing will be necessary to remove the relatively insoluble silver salt so that normally some will remain in the film and this in turn will be changed to silver sulphide by the action of the sulphuretted hydrogen in the air. Any undissolved silver halide will on exposure to light be changed to photo-halide.

The only safe rule is to leave all prints and negatives in the fixing bath for double the time necessary for the milkiness to disappear and then wash thoroughly. Very minute traces of silver left in the film can be detected by the sweetness on tasting a corner of the film.

3. If the film is not completely immersed in the fixing bath it may appear to be completely fixed, though in spots it may only be fixed as far as the first stage, with the result that on exposure to the air and light yellow stains appear.

4. A common cause of silver stain when handling roll film is developing and fixing with two lengths of film placed back to back. Although this may save space, it is false economy, because it is impossible to wash the backs of the films which stick together. The result is that hypo containing silver is left in the gelatine backing which turns to silver sulphide on exposure to air, so that while the emulsion side of the film is clear the gelatine backing is stained.

Removal of Yellow Silver Stain.—Silver stain cannot be removed by bleaching and redeveloping, as in the case of oxidation stain, because this has simply the effect of converting the yellow silver sulphide to silver chloride, and then to silver so that the yellow stain is changed to a black stain of metallic silver.

There is no way of always completely removing silver stain, though the following methods are frequently successful :—

1. After thoroughly washing to remove any hypo, bathe the film in a 1 per cent. solution of potassium cyanide. Remember that cyanide is a deadly poison, and a solution in water emits fumes of poisonous hydrocyanic acid, so that it should be used only in a well ventilated room. The cyanide will dissolve any silver thiosulphate present and some silver sulphide, though in time it dissolves the silver image so that the film should be removed from the bath and thoroughly washed as soon as any signs of reduction of the image appear.

In the case of an old negative treatment with a weak solution of acid permanganate, washing, and then immersing in the cyanide will often remove obstinate stains.

2. Copying the negative or print through a G filter as described above will reduce, but not always remove silver stain completely.

To summarise. A yellow stain may consist of one or more of the following substances, silver sulphide, silver thiosulphate, silver halide or photo-halide together with oxidation products of the developer. If it is decided to attempt its removal first make a copy through a suitable filter in case the photograph is ruined in the subsequent treatment. Then find out by a preliminary test the exact nature of the stain. This is done by cutting a narrow strip from the edge of the film, washing and bleaching and redeveloping as above. If the stain is entirely removed and is not replaced by a black deposit, the stain is pure oxidation stain and the entire negative may be treated in this way. If the stain is only partially removed, treat the narrow strip with cyanide as for the removal of silver stain, wash well, and if a transparent yellow stain remains treat this as for oxidation stain. The degree of success in removing the stains from the narrow strip will serve as a guide to the procedure necessary for the rest of the negative.

Yellowish-Brown Stains.

These are usually caused by contact with iron or iron rust. In the case of motion picture film if the iron film reel on which the film is usually wound is rusty the rust is scraped off during re-reeling and settles between the convolutions of the film causing the stain. The stain may be identified by placing a drop of a 50 per cent. solution of nitric acid on the stain and then adding a drop of ammonium thiocyanate. A deep red coloration indicates the presence of iron.

The stains are usually removed by bleaching and redeveloping as when removing developer stain.

Brown Scum.

This occurs in deep tank development when developing roll film or motion picture film. If the developer does not contain enough preservative, a layer of insoluble oxidation product of the developer forms as a scum on the surface, and this is picked up by the film.

The scum forms most readily on the surface of the fixing bath if it is allowed to stand for any length of time, for instance, over week end. When this is exhausted and con-

tains an excess of silver salts, the sulphuretted hydrogen in the air reacts with the silver thiosulphate at the surface of the liquid forming silver sulphide which floats as a scum. This is picked up when the film is immersed in or withdrawn from the solution.

The scum has a peculiar appearance under the microscope and is characterised by a series of cracks or fissures which

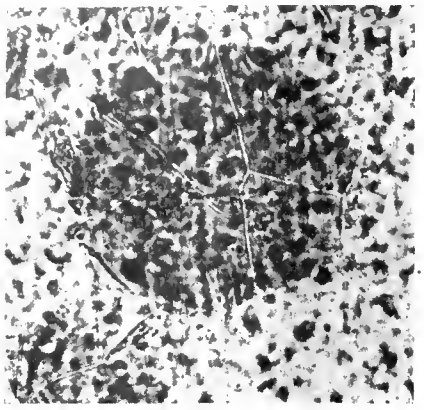

Fig. 3.

are formed when the scum is broken up on immersion of the film in the tank. Fig. 3 shows an enlargement of such a scum in which the cracks or fissures are very pronounced.

Green Stain.

This is another term for dichroic fog which appears as a yellowish green and sometimes reddish metallic sheen by reflected light or when looking at the film and pink by transmitted light or when looking through the film against a source of light. In view of this dual character it is called dichroic or two-coloured fog.

When examined under the ultra microscope the fog is seen to consist of ultra-microscopic particles which by chemical analysis have been shown to consist of metallic silver. The size of the particles determines their colour by transmitted light, those that are red in colour being smaller than those which are green and blue.

Dichroic fog is always formed either in the developer or fixing bath.

(a) In order that the deposition of fog may take place in the developer some solvent of silver bromide, such as hypo, ammonia, or an excess of sulphite or carbonate, must be present when under certain conditions the dissolved silver is reduced to metallic silver in a very fine state of division, particularly in the shadows or unexposed portions of the emulsion where no bromide is liberated during development. A pyro-ammonia developer is very apt to give dichroic fog, especially with fine grained emulsions for this reason.

Fine grained emulsions in which the grains of silver halide are very small, and, therefore, more readily soluble are most susceptible to this form of fog, especially if the development is forced.

(b) Dichroic fog is most generally formed in the fixing bath, especially if the fixing bath is not acid, or if it is old and exhausted, when it contains an excess of dissolved silver and spent developer. In such a case, as the silver halide is slowly dissolved out of the emulsion, it is reduced to finely divided metallic silver by the developer present. It is possible to get dichroic fog with a fresh fixing bath of plain hypo, because the silver salt is redeveloped back to dichroic silver by the developer carried over by the film to the fixing bath. This is especially true if the gelatine coating of the film is abnormally thick, and if the developing and fixing solutions are warm. The developer does not have time to diffuse out of the gelatine film before the hypo begins to dissolve away the silver halide, which is reduced *in situ* to dichroic silver. A slow fixing emulsion is apt to give dichroic fog for the above reasons.

The formation of green fog in the fixing bath is also facilitated by the presence of ammonia so that a fixing bath containing ammonium chloride (which is sometimes added to accelerate the rate of fixing) will give fog unless the bath is kept acid by virtue of the ammonia liberated by the action of the alkali in the developer carried over by the gelatine film.

Dichroic fog can also occur in a fresh fixing bath if two films or prints stick together face to face, thus forming local pockets containing developer. Such a condition is ideal for the formation of green fog, namely, an insufficiency of hypo in the presence of an excess of developer.

Stencil effects are sometimes produced in the shadow portions of a negative or print when another film with dense lettering adheres to the film in the fixing bath. The result is that the film is covered with dichroic fog except in those places where it was in contact with the lettering. This is because the developer in contact with the clear portions of the lettered ngative is comparatively fresh, but wherever the lettering occurs the developer is comparatively exhausted, so that no fog is formed in the region of the lettering, thus producing the stencil effect. The potassium bromide which is locally formed in excess in the region of the lettering (as a product of development) also tends to retard the formation of the fog, thus accentuating the stencil effect.

Prevention of Dichroic Fog.—Dichroic fog may be prevented as follows:—

(a) By keeping the fixing bath acid by renewing at frequent intervals and, if possible, rinse the film well before fixing, or use a stop bath between developing and fixing. In this way the quantity of developer transferred to the fixing bath is reduced to a minimum.

(b) By adding potassium idodide to the developer, say, 1.5 grams per litre or 20 grains per 32 ounces. This has the effect of converting any silver halide dissolved by solvents in the developer to silver iodide, which is reduced to silver only with difficulty, so that the tendency for dichroic fog to be formed is restrained.

Removal of Dichroic Fog.—Since dichroic fog consists of particles of silver in a finer state of division than the particles composing the image, they are more readily attacked, and therefore dissolved by solvents of silver, such as potassium cyanide, acid permangante, etc. Advantage may be taken of this fact in removing the fog as follows:—

(a) Bathe the film in a 1 per cent. solution of potassium cyanide and rub the film gently with a tuft of cotton. As soon as any visible signs of reduction of the image occur wash well in running water. (Note previous remarks about poisonous nature of potassium cyanide.)

(b) In place of cyanide the less poisonous thiocarbamide, or thio-urea, may be used. This works best in an acid solution, such as the following:—

Thio-urea	1 gm.	15 grs.
Citric acid	1 gm.	15 grs.
Water to	100 ccs.	3 ozs.

(c) Treat the film with a weak solution of Farmer's reducer made by adding a little potassium ferricyanide to a 5 per cent. solution of hypo, or with a weak acid permanganate solution.

(d) An ordinary acid fixing bath will slowly dissolve silver especially in warm solution. This can be readily seen by placing a print in a warm solution of acid hypo when the image will be appreciably reduced in a very few minutes. A hypo bath is, therefore, useful for removing dichroic fog. Allow the film to stand in the hypo bath if necessary for twenty-four hours or longer until the fog is removed, though the action can be hastened by gently warming.

Blue-Green Stain.

A general bluish-green stain is often caused by an exhausted chrome alum stop bath or fixing bath at high temperatures, especially with certain grades of matt paper. The remedy is

to use a fresh bath at normal temperatures because there is no known way of subsequently removing this stain.

Miscellaneous Stains.

Blue stains on sulphide-toned prints caused by particles of iron are in the class of spots, and will be dealt with as such.

Deep lemon-yellow stains are often caused by insufficiently fixing glossy prints developed with a non-abrasion developer containing potassium iodide. The potassium iodide converts the surface layer of the silver bromide emulsion to silver iodide, which is deep lemon-yellow and which fixes much more slowly than silver bromide and does not darken on exposure to light.

Fig. 4.

The stain may usually be completely removed by bathing in a fresh fixing bath.

Stains due to aniline dyes, indelible pencils, and red and black writing inks are removed by bleaching and redeveloping as above or photographically. In the case of some samples of red ink a slight trace of stain remains after the chemical treatment, but this can be removed photographically. Figs. 4 and 5 illustrate how ink stains may be removed by chemical treatment. Fig. 4 is a copy on an ordinary plate of a photograph stained with "waterproof" red ink.

Fig. 5.

Fig. 5 is a copy of the same photograph after the red stain was removed by bleaching in the permanganate chloride bath and redeveloping. No sign of the stain is visible.

J. I. Crabtree.

ELECTRICAL FACTS FOR PHOTOGRAPHERS.

The writer, whose work brings him in contact with a large number of electricity consumers, photographers among others, finds that few have anything but a hazy knowledge of electricity and its terminology. In view, therefore, of the growing use of electricity both in studio and workroom, an explanation will probably be of interest, as it is generally difficult to extract any lucid information from either the man who comes to read the meter, or the electrician who is called in to attend to the installation.

It is a pity that those connected with the trade still persist in surrounding the subject with much mystery, though it must be confessed that ignorance of the science is often the reason for adopting an attitude of profound reticence.

An enormous amount of instructive literature has been published in connection with the artistic, chemical and optical side of photography, but the photographer anxious to experiment a little in electricity has had to content himself with meagre details. Many a man, though quite familiar with batteries, small coils, and bells has been afraid to attempt any experiments with the supply obtained from the public mains, because his initial effort resulted in a sudden and alarming pyrotechnical display, the blowing of the main fuse and consequent total darkness in the house, and a plaintive appeal to the generating station to "send a man round immediately."

As an instance, a friend of the writer, fired by a desire for knowledge, permitted so much current to enter his premises with a rush as to blow the fuse in the nearest sub-station, with the result that several other houses were suddenly plunged in gloom. This feat required a good of explaining away to the mechanic deputed to investigate the affair, and, in fact, he quite failed to take a reasonable view of the situation until presented with several medallion portraits of the late Queen. Had the intrepid investigator possessed even an elementary knowledge of Ohm's law he would not have been led into this disaster.

The writer also remembers a dreadful experience he had when asked to work an arc-lamp projection lantern at a lecture given in a hospital. The lecture took place in a room not generally used for the purpose, and the responsibility of fitting a fuse large enough to carry the current rested upon a factotum who "knew all about electricity." Just before the students entered the room the writer, who had arrived in a hurry, struck the arc to see that all was well. It gave a splutter, a sickly gleam for a second or two, and went out! The factotum had also gone out, and so could not be found. Suffused with shame and perspiration, and thinking words that would have put a drill-sergeant to the blush, the writer dashed about the place in an endeavour to locate the fuse-board. It was eventually discovered in a corridor, 10 ft. above the ground, where it had evidently been placed by an insane contractor. A ladder and a piece of fuse wire of the correct calibre soon put matters right, but the eminent surgeon conducting the lecture cast a somewhat cold and unsympathetic eye upon the lanternist for the rest of the evening.

The consumer hears a good deal about volts, amperes, and watts, the first-named being often applied in the most haphazard way. In order, therefore, to explain these three terms as simply as possible (ignoring all considerations as to what really constitutes an electric current) it is convenient to take as an analogy a pipe through which water is flowing. In this case the volt, the unit of electromotive force (E.M.F.), corresponds to the pressure of the water in the pipe, and the ampere, the unit of rate of flow, corresponds to the rate at which water is passing through the pipe at any given instant. It is popularly referred to as the "strength" of the current. The watt, the unit of power, is the product of the pressure and the rate of flow, i.e., watts = volts × amperes, as it is obvious, bearing in mind our analogy, that the power transmitted by the water is proportional to the rate of flow multiplied

by the pressure. In other words, supposing the water is required to actuate some form of wheel, it is clear that until there is a pressure to force it through the pipe no work will be done, and, assuming the stop-cock to be shut off pressure applied to the water without any flow will have the same result. This, however, is only true of direct-current circuits and of alternating-current circuits in which the load is a pure resistance one, such as glow lamps, radiators and (approximately) arc lamps, and if the load is associated with any form of magnetic winding, the watts will be less than the product of V and C.

Strangely enough, few electricity users grasp the fact that they are really purchasing power from the generating station, no matter whether the current is used for lighting, heating, or motors.

The watt is the basis of the Board of Trade unit, or kilowatt-hour (kilo=1,000), and is the equivalent of 1,000 watts passing for one hour, or conversely, one watt passing for 1,000 hours. It will, therefore, be seen that a current of 10 amperes at 100 volts flowing continuously for one hour would register one B.O.T. unit on the meter.

The term unit is sometimes misapplied by people who ought to know better. It is not uncommon for a salesman, in answer to a query regarding the current consumption of an electric heater to state that it "takes so many units." This has no meaning, unless the time is stated, as it might consume a unit an hour, a day, or a week. When inspecting such apparatus, one should nail the salesman down to a definite guarantee as to the number of units per hour. A simple calculation will then usually convince the prospective purchaser, unless he is very affluent, that he will adopt some other form of heating.

The watt is also used in the rating of metallic filament lamps instead of candle-power, which term is confined to carbon filament lamps. The former take about 1¼ watts per candle, and the latter 4 watts, so their relative economy may be readily calculated. The most recent development, the half-watt (gas-filled) lamp, takes, as its name implies, about half a watt per candle.

Electricity meters were generally marked "units" above the indicating dials, but a few years ago the Board of Trade desired the words "kilowatt-hours" to be substituted. This distinction without a difference probably confused many consumers, as doubtless they were unaware of the terms being synonymous.

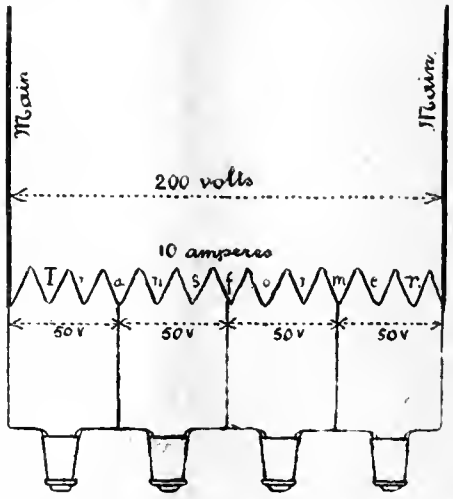
There is also a type of instrument, known as an ampere-hour meter, which indicates the number of ampere-hours. A little consideration will show that such a meter registers only the quantity of electricity passing through it, and takes no account of the voltage. Provided the voltage remains constant it will correctly indicate the watts, and the consumer will therefore be charged fairly for the power used. Should the voltage drop, however, he will still be charged the same, though the actual power will naturally be less.

Reverting to the question of electric heating, it may be that the photographer wishes to take advantage of this method for a special purpose owing to the absence of fumes. For drying plates, etc., or other occasional use, the high cost might be counterbalanced by the advantages. It is therefore well to note that electric heaters are of two kinds, radiators and convectors.

A "radiator" is strictly a heater which throws out radiant heat like that from the incandescent coals of a clear fire. Such heat passes through the air without warming it. A "convector," on the other hand, is a heater at a much lower temperature, and acts by warming the air which passes over it. Actually an electric radiator as sold combines both methods, and the larger part of its heat is distributed by convection.

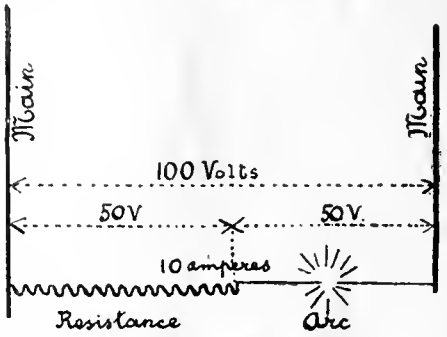
It is perhaps difficult to form a mental impression of the volt and ampere, but it may be mentioned that when in good order the Daniell cell gives rather more than one volt and the bichromate cell about two volts. The current consumption by the average street arc lamp is about ten amperes. A 50-watt metal filament vacuum type lamp takes half-an-ampere on a 100-volt circuit. In the latter connection it is well to observe that on a 200-volt circuit the lamp takes only half the above current, and it will therefore be apparent that thinner wires can be employed in carrying out installations of higher voltage, thus saving a considerable sum in cost of copper.

It is perhaps hardly necessary to explain that used in connection with a dynamo or other generator the



Arrangement of four arc-lamps and auto-transformers.

term voltage means the electrical pressure supplied by the machine. Station engineers know that should a steam turbine "run away" owing to an accident to the governor, the voltage of the generator will rise with such fearful rapidity that before steam can be shut off the internal parts will be fused into a shapeless lump. In connection with lamps one often hears the query "Is it of the right voltage?" and a great many consumers fail to understand that in this case the term is used to denote nothing more than the voltage of the circuit on which the lamp may be *safely* used. The amount of current that will pass through the filament is determined by the resistance of the filament and the voltage of the circuit. The amount remains constant so long as these two factors are unaltered. The lamp-maker therefore adjusts the length and thickness



of the filament so that at a certain voltage the right amount of current passes to secure the highest efficiency with a reasonable life of the lamp.

ELECTRICIAN.

(To be continued.)

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries, August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, May 9 to 13.

DAYLIGHT DEVELOPMENT. No. 13,343. Daylight development of roll films without paper covering. H. G. Chaney.

CAMERA HOODS.—No. 13,673. Hoods for photographic cameras. T. Peacock.

DRY-MOUNTING.—No. 13,352. Plates for dry-mounting of photographs. J. H. Stean.

DEVELOPING.—No. 13,212. Developing-tanks for photographic films. F. Torkington.

STEREOSCOPY.—No. 13,300. Mechanical stereoscopy. J. W. F. White.

APPARATUS.—No. 13,499. Apparatus for developing, fixing, toning, washing, and drying photographic films. P. L. Burger.

APPARATUS.—No. 13,640. Photo-printing apparatus. R. P. Clarke and H. C. Dering.

COLOUR PHOTOGRAPHY.—No. 13,534. Multi-colour screens for photography. J. H. Christensen.

CINEMATOGRAPHY.—No. 13,511. Cinematographic devices. J. H. Corthesy.

CINEMATOGRAPHY.—No. 13,157. Film and process for representation of cinematograph pictures. B. Hutter.

COLOUR CINEMATOGRAPHY.—No. 13,637 (or 13,631). Manufacture of multi-colour screens, films, etc., for natural colour cinematography, etc. J. Camiller and A. Hay.

STEREOSCOPIC CINEMATOGRAPHY.—No. 13,125. Stereoscopic cinematograph camera. S. Hockly and A. S. Willmot.

CINEMATOGRAPH-PHONOGRAPH.—No. 13,383. Reproduction of sound and synchronisation with projection of moving pictures. G. D. Lemon, C. E. Tidswell, and C. E. Tidswell and Co.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

REFLEX CAMERAS.—No. 158,194. (September 20, 1919.) The complete release of the shutter for instantaneous operation, and the release and arrest of the shutter in its open condition for time and bulb exposures, are determined by the position or positions taken up by the mirror after release and preparatory to an exposure, the release of the shutter being effected by detent mechanism actuated by the mirror.

The mirror 17, fig. 12, is normally under the influence of a spring coiled on the axis 21, tending to raise it, and is held in the focussing position by an arm 30, fig. 5, on the axis 21. The arm 30 has a series of projections 31, 32, 33, the projection 31 engaging a spring catch 34 on a detent arm 36 when the mirror is set for focussing by the handle 90. The arm 35 is operatively connected with a release and timing lever 36, which has a catch 94 to engage one or other of the stops 31, 32, 33, on the arm 30 according to the setting of the roller-blind shutter for a "B," "T," or "I" exposure.

The mirror pivot 21 also operates links 26, 28, 27, 29, fig. 12, whereby, when the mirror rises for an exposure, the link 29 engages the spring pawl 80 which holds the shutter in set position.

The movement of the mirror controls the shutter for different exposures according to the setting of a pin 42, fig. 5, attached to a plate 140 having shoulder stops 98, 99, 100, which limit the angular movement of the release lever 36. For an instantaneous exposure the pin 42 is moved to the "I" position and brings the shoulder 100 opposite a projection 41 on the lever 36. On operating the release 37 the arm 30 and mirror are released, and the latter moves right up to a horizontal position against the stop 101, the shoulder 100 holding the lever 36 and catch 94 thereon clear of any of the projections 31, 32, 33. The arm 29, fig. 12, then releases the shutter pawl 80.

For time exposures the pin 42 is moved to the "T" position and brings the shoulder 99 opposite the projection 41, so that on operating the release 37 the catch 94 on the lever 36 engages the stop 32 on the arm 30, and on the return of the release 37 the catch 94 engages the projection 33. The corresponding movement of the arm 29, fig. 12, is to release the shutter pawl 80, but to be

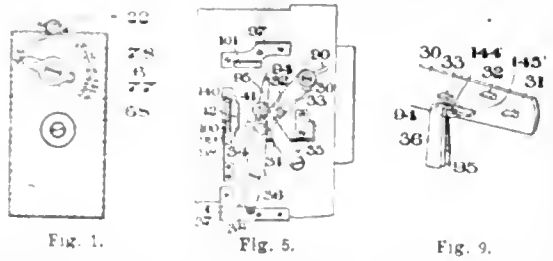


Fig. 1. Fig. 5. Fig. 9.

held in the path of a projection 96 on the gear wheel 66 of the shutter arresting it in open position until the release 37 is again actuated to release the mirror from the catch 33.

For bulb exposures the pin 42 is set in the "B" position bringing the stop 98 into position to arrest the projection 41. On operating the release 37 the catch 94 arrests the projection 31, on the arm 30 and the corresponding movement of the arm 29 is to release the shutter pawl 80 and engage the projection 96 holding the shutter open as long as the release 37 is held.

To cushion the impact of the mirror lever 30 with the stops and its movement after an instantaneous exposure the lever 36 has a yielding leaf spring 95, fig. 9, which snaps into position under the stops when they are engaged by the catch 94, and in

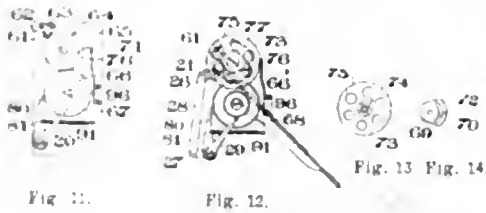

Fig. 11. Fig. 12. Fig. 13. Fig. 14.

the case of an instantaneous exposure a stop 145 engages the catch 94 when the arm 30 reaches the horizontal position.

To allow the mirror to be reset a cam 144 on the arm 30 moves the spring 95 into an inoperative position when the release lever 36 returns to normal position.

The shutter comprises two blinds, one 43, fig. 17, with an aperture 47, and wound on a spring roller 46 and the central part 45 of an upper roller, and the other wound on a spring roller 48 and with tapes 44 wound on rollers 49, 50, adjacent to and on the same spindle as the upper roller. The roller 45, fig. 15, is keyed to the spindle 51 and the rollers 49, 50, are connected to the spindle 51 by internal clutches each consisting of a ratchet member 52 keyed to the spindle 51 by a pin and slot 144, 145, fig. 16, and pressed into engagement with a freely mounted companion

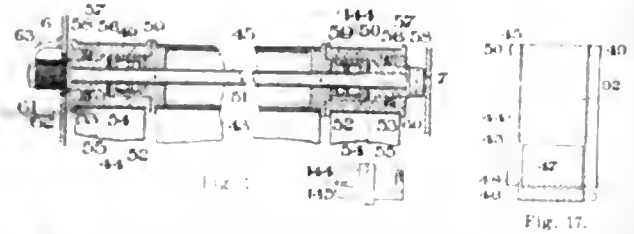

Fig. 15. Fig. 17.

member 53 by a spring 59. The members 53 have shoulders 54 gripping the rollers 49, 50 under the action of spring washers 56 held in place by screws 58 and washers 57.

The shutter is wound by a knob 68, figs. 1 and 12, which rotates wheels 69, 61, the latter gearing with the pinion 61 on the spindle 51. The rotation of the spindle and the roller 45 carries with it the side rollers 49, 50, through the friction of the spring washers 56. When the blind 44 has been fully unwound from the spindle 48 the apertured blind 43 can be further wound on the roller 45 to an adjustable extent forming a slit of

pre-determined size. On running down for an exposure when the blind 44 is fully re-wound on the roller 48, the blind 43 continues to wind on the spring roller 46 to re-close the slit by the action of the clutch members 52 overrunning the members 53, the rollers 49, 50, remaining stationary.

The setting of the shutter is controlled by a setting knob 77, figs. 1 and 12, which positions a notched disc 73, fig. 13, freely mounted on the shaft 65 of the wheel 64 and held by a spring catch 76. The disc 73 has a pin 74 extending into a slot 72, fig. 14, of a plate 69, which is also freely mounted on the shaft 65 and itself carries a pin 70. This pin is normally adjacent to a pin 71 on the pinion wheel 64. On rotating the winding knob 68 and the pinion 66 the blinds of the shutter are wound, and after one revolution of the wheel 64 the pin 71 engages the pin 70 on the plate 69, and the blinds are further wound to the extent allowed by the slot 72 and until rotation is stopped by the pin 74 on the setting-disc 73 integral with the knob 77.—P. G. Mason and Newman & Guardia, Ltd., 17, Rathbone Place, London.

COLOUR CINEMATOGRAPH CAMERA.—No. 135,169 (November 9, 1918). This invention relates to a camera fitted with light filters and capable of working at a speed suitable for the production of negative images of different colour sensations for use in the manufacture of pictures in natural colours by the three-colour system.

The invention has for its object the provision of an apparatus in which the three serial negative images of different colour sensations are taken through one and the same objective as quickly as possible after each other; the closing and opening of the shutter, the changing of the requisite light filters and the displacement of the film stock being automatically effected, while the operating speed may be varied within wide limits for example by the regulation of a tension spring.

The shutter disc carries uniformly arranged selective light-filters, adapted to rotate and by means of cam-shaped surfaces on its periphery operates the intermittent film-moving mechanism which comprises a U-shaped frame having latches, pawls, or claws which engage in the perforations in the film in such manner that the film is drawn forward by a length corresponding to that of a picture surface and is brought to rest before the next exposure takes place.

Cam-shaped surfaces on the periphery of the shutter disc correspond in number to the light-filters, and engage a roller at the end of an oscillating arm mounted on the axle member of another oscillating arm which is connected with the U-shaped frame by means of a link.

The latches or pawls are mounted on a frame sliding to and fro on the plate for guiding the film and which is connected to a link attached to one of the oscillating arms.

There is a shock-absorbing device for the shutter disc, comprising an air dash-pot and a spring-controlled hook which engages with a pin attached to the shutter disc. Serge de Procoudine-Gorsky, Granstad, Konnerud, near Drammen, Norway, formerly of Petrograd, Russia.

The following complete specifications are open to public inspection before acceptance :—

CINEMATOGRAPHY.—No. 161,545. Cinematographic screens. J. Elmington-Darling.

REGISTRATION OF COLOUR PRINTS.—No. 161,578. Process for causing single-coloured partial pictures to register on paper. Soc. Anon. per la Fotografia Autopancromatica.

FILMS.—No. 162,266. Process for the preparation of photographic films permeable to water. Soc. Anon. La Cellophane.

CINEMATOGRAPH-PHONOGRAPH.—No. 162,274. Apparatus for simultaneously reproducing optical images and sound waves which have been photographically recorded on a film. E. Reisz.

CINEMATOGRAPHY.—Nos. 162,278 and 162,279. Motion-picture films. Pathé Cinema Anciens Etablissements Pathé Frères.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

PASTINELLO.—No. 413,292. Projection screens for motion picture theatres and for other optical projection apparatus. The firm trading as Bardilis, 73, Great Titchfield Street, London, W.1, manufacturers. March 10, 1921.

New Apparatus.

The Thurlow Printing Table. Made by The Thurlow Manufacturing Co., Thurlow Street, Walworth, London, S.E.17.

THIS new pattern of printing machine is designed for making single prints up to 12 by 10 size, and also strip prints, either six postcards or four cabinets, on each strip. The apparatus is made in the form of a table occupying a floor space of 3 ft. 6 ins. x 1 ft. 9 ins., and of height (to table top) 3 ft. Below the negative bed, which is a glass plate, is the light-box, which is provided with means for raising or lowering the lamps for adjustment of the strength of light according to the density of the negative. Grooves are also provided in the upper part of the light-box for the insertion of ground glass, as required for thin negatives, or of vignetters.

Arranged to right and left on the table top are the necessary guides and stops for postcard or cabinet printing on the customary strips. Exposure is made by foot treadle, so that the hands of the operator are free for the manipulation of paper or cards. Moreover, the light in the box is switched on only by the final pressure of the treadle, obviating the possibility of accidental fogging. Interchangeable pressure boards and masks for postcard and cabinet sizes are provided; other sizes can be supplied to order. The whole apparatus is altogether of workmanlike design, and is substantially made in polished oak. The price is £14, carriage paid in England.

New Materials.

Barnet Matt Self-Screen Plates. Made by Elliott and Sons, Ltd., Barnet, Herts.

THERE was a mention some weeks ago in our columns respecting the usefulness of a negative plate coated on the glass side with a matt film for the purpose of facilitating retouching with pencil, stump, etc. Messrs. Elliott then informed our readers that they could supply a plate of this kind, and have now sent us a specimen in the shape of their well-known Self-Screen plate provided with the matt backing. There is no doubt that among both portrait and landscape photographers there is a considerable demand for a plate of this kind. The fine matt coating on the glass side provides one of the readiest means for carrying out hand work, and, moreover, is a measure against halation. If our memory serves us correctly, a plate with a matt surface on the glass side was issued many years ago, specially for its prevention of halation. That was before the present era of "control" in various forms, and now that the facility for hand work can be obtained in combination with alleviation of halation, very many should have good reason for taking advantage of the new introduction.

Verona Chloro-Bromide Paper. Made by Elliott and Sons, Ltd., Barnet, Herts.

IN this new grade of development paper Messrs. Elliott, by preparing an emulsion of only one-quarter the speed of bromide paper, have provided photographers, and particularly the makers of professional portraits, with a printing medium of most distinctive and beautiful quality. "Verona" is a paper of extremely delicate cream tint, yielding a warm black tone by straightforward development with an M.Q. formula. The tint of the paper base is of the faintest; it is, perhaps, an exaggeration to call it a tint, for it more closely resembles the mellowing with age which a pure paper undergoes. This quality, in conjunction with the warm black of the image, produces an effect very similar to that of a mezzotint engraving. And as regards the photographic quality of the image, the prints exhibit a fine range of gradation creditable to any development paper. The new medium is, in short, a notable addition to the many varieties of development papers, which are now offered to photographers, and worthily ranks—which is saying a good deal—with the distinctive papers which Messrs. Elliott have themselves issued from time to time. The speed of "Verona" is convenient for both enlarging and contact printing, whilst the manipulation in no way differs from that of a bromide paper. The tone given by the developer recom-

mended by the makers is of very pleasing warmth; a colder tone may be obtained by using a considerably smaller quantity of bromide in the developer; and if prints of extra warmth are required, the customary sulphide-toning process works excellently with the paper.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, May 24, the President, Dr. G. H. Rodman, in the chair.

A number of papers, dealing with the lighting of cinematograph and portrait studios, arranged by the Scientific and Technical Group, were read.

Mr. J. E. Elvey dealt generally with the types of lighting equipment in cinematograph producing studios and showed photographs of the installations used by notable producers of cinema drama films in this country and America.

A paper by Mr. Leon Gaster was read for him by Mr. J. S. Dow, and considered somewhat more specifically the conditions of efficient illumination in both portrait and cinema studios in relation to the type of illuminant and the sensitiveness of the photographic emulsion. The disparity between the maximum spectral intensity of artificial light-sources and the maximum spectral sensitiveness of plates was emphasised by curves representing these properties and stress laid on the necessity of plate-sensitiveness being brought into correspondence with the distribution of spectral intensity of the light-sources.

The third paper by Mr. John W. P. Walsh, of the National Physical Laboratory, dealt more precisely with the elements of the measurement of the intensity of light-sources, the illumination produced by them and the reflected light-intensities. Measurements of reflection coefficients of a number of human faces had been made and yielded an average of about 40 per cent., as against about 80 per cent. for white blotting paper and 3 per cent. for black velvet. The authors showed examples of polar curves representing the spherical distribution of light, and pointed out the information they gave of illumination of horizontal and vertical surfaces. They referred to the systems of distribution of light, either wholly by diffuse reflection, which was the most efficient, or by diffusion through a partly transparent medium. In an animated discussion which followed, Mr. Marcus Adams criticised most of the photographic work in the cinema studios for its over-lighting.

Mr. Angus Basil said that cinema photographers appeared not to realise that good lighting consisted in as close an approximation as possible to daylight, otherwise they would not employ powerful lights in so many different positions.

Mr. Ferguson pointed out that visual measurements of lighting were very little use; they wanted photographic measurements.

Mr. Renwick added that users of lighting systems needed a more rapid actino metric test than was at present available.

Mr. A. C. Banfield emphasised the fact that portrait photographers required to have a light-equipment capable of responding to extreme requirements, and at the same time of the utmost convenience in manipulation. For that reason he thought it was difficult to find a more suitable source of light than the half-watt lamp, but plate makers should devote themselves to making fast red-sensitive plates, preferably of minimum green sensitiveness for facility of development. Mr. Banfield drew a plan of his own installation of half watts, the lamps being hung in pairs down one side of the studio and having two lamps more widely separated high up on the wall behind the sitter. By using a given four or five of the dozen lamps he could obtain any type of lighting.

Mr. Rawson, as a cinema producer, spoke of the advantage of using arc lamps because the negative sensitive film had its chief sensitiveness in the blue. He would like to see a film of maximum sensitiveness in the middle portion of the spectrum, and then they could take advantage of the properties of the gas-filled lamps.

Mr. C. P. Crowther remarked upon the extraordinary differences in candle-power of electric installations which permitted equally short exposures. He thought that the size of the studio was the chief factor in such cases, reflected light from the walls being effective in a small studio, whilst it was lost in a larger one. He said that Mr. Pirie Macdonald, in his New York studio, arranged a velarium, and further confined the light by the use of movable screens arranged so as practically to create a studio within a studio.

Further discussion showed the considerable interest in the exchange of view between those engaged in the scientific design of lighting installations and those having to use them.

On the proposition of the chairman a very hearty vote of thanks was accorded to the readers of the papers.

CROYDON CAMERA CLUB.

Mr. J. A. Sinclair gave a lantern-lecture, entitled "Croydon Waters." Many as are the useful purposes water serves, notably as a heavily taxed commodity when in generous admixture with more cordial fluids, yet the subject, naked and unadorned, seemed somewhat inappropriate for Croydon. Perhaps even more so, when the revelation came that the River Wandle, which rises in crystal purity close to Croydon, and from association with less favoured districts finally oozes dirtily into the Thames at Wandsworth, was to be the theme. For, as the secretary expressed it, what manner of man was he who thought he could tell or show the members anything new about their own pet preserve.

Mr. Sinclair succeeded admirably in doing so, firstly with a highly interesting epitome of English history which happened along its banks, and secondly by unearthing many unknown beauty spots, and presenting them vividly and pictorially in a first-class set of slides, the majority of which had never experienced a lantern-warming. A capital lecture on the modest yet picturesque little Metropolitan stream, famous, he said, for an abortive attempt by Ally Sloper to reach the Croydon club by water. On the same unimpeachable authority one also learnt that Anne Boleyn lost her somewhat flighty head owing to an incurable habit of eating biscuits in bed from which, apparently, her husband derived no crumbs of comfort. Side-lights of history like this made the lecture rich in educational lore.

In the discussion Mr. H. P. C. Harpur expressed unqualified approval of the slides untainted with destructive criticism. Only when exhibiting his own has the auspicious occasion been equalled. Mr. Sinclair's slides, he said, were paramountly juicy; indeed, from the juicy standpoint they were the most juicily juicy he had ever set eyes upon. In addition, their atmospheric charm and "rescending" quality were superlatively gorgeous. As a slight counterblast, Mr. F. Ackroyd then measured up the lecturer for having omitted from the list of celebrities who lived at Mitcham the name of Mr. Mallaby Deeley. Mr. A. S. Newman, on being called upon to speak, contented himself with remarking that until he had seen his partner's pictures he had never realised the beauties of Mitcham.

Replying to questions, Mr. Sinclair said that the cameras used by him were the "Una" and a reflex respectively fitted with

3- and 6-inch lenses. A 9-inch f/6.3 "Telecentric" was also occasionally employed, excellently adapted for recording street groups, as the distant standpoint of the photographer did not attract attention. For this type of lens an aperture of f/6.8 was sufficiently rapid, and was indeed requisite for the sake of depth of field. He invariably used ultra-fast brands of plates, and some of the slides were from panchromatics, which could now be obtained of extreme speed. A most hearty vote of thanks was accorded him for a lecture which must have involved a lot of trouble to a busy man cheerfully undertaken for his many friends at Croydon.

A catastrophe threatened early in the evening owing to the absence of the honorary steward, and that both the secretary and his satellite had left their keys of the refreshment safe at home. The lock is a tricky one, but two experts, Mr. Vivian Jobling and Mr. A. F. Catherine, set their hands to the job and picked it with consummate ease.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held on May 13 at 35, Russell Square. There were present Mr. Swan Watson (president), Mr. Frank Brown (past president), Mr. R. N. Speaight (treasurer), with Messrs. Marcus Adams, A. Basil, A. Bennett, W. B. Chaplin, G. Chase, A. Corbett, C. F. Dickinson, Alfred Ellis, W. E. Gray, R. Haines, G. Hana, W. Illingworth, H. St. George, F. G. Wakefield, W. H. Wedlake, and Lang Sims (secretary).

Apologies for absence were announced from Messrs. Chapman, Chidley, Fry, Lambert Read, and Wheeler. Mr. Chidley congratulated the officers and Council upon the success of the Congress, and also expressed himself in favour of the title "The Institution of Professional Photographers" when the Association was incorporated.

It was necessary to appoint officers and committees under the old constitution, and Mr. Basil proposed and Mr. Chase seconded the re-election of Mr. Ellis to the chair, and this was unanimously agreed to. Mr. Illingworth proposed, and Mr. Watson seconded, the re-election of Mr. Speaight as treasurer, and this also was unanimously agreed to. Some doubt was expressed whether the secretary came up for election, but in any event, on the informal motion being put from the chair, it was agreed with acclamation that Mr. Lang Sims be asked to continue in that office.

It was agreed, on the motion of Mr. Frank Brown, seconded by Mr. Illingworth, that the Finance Committee should consist of Messrs. Chase, Corbett, Haines, and Wakefield, with Messrs. Ellis, Watson, and Speaight *ex officio*.

Mr. Corbett proposed, and Mr. Chase seconded, the re-election of the "Circular" Committee as follows:—Messrs. Adams, Haines, Hana, and Wakefield, and this was agreed to.

The secretary read the names of fourteen new members, twelve of whom had joined at the Congress.

The secretary reported that since the last meeting a number of further inquiries had been received with regard to the proposal of the Eagle, Star, and Dominions Company. A number of letters had also come to the Association thanking the Council for the excellence of the Congress arrangements. A dispute between two members concerning a question of copying was the subject of correspondence. One photographer had made an enlargement from a negative made by the other, and at the special request of the mother of the sitter (a soldier well known locally who had lost his life while fighting) had exhibited the enlargement in his window. The secretary was instructed to write urging that the exhibition in the window should not be continued except by arrangement with the photographer who did the original negative.

Two members wrote that they had been circularised by a photographer who suggested participation in certain local schemes which he urged would be remunerative. The particulars were only to be divulged on a certain small payment. The secretary was instructed to write asking the gentleman in question to furnish such information as to his scheme as would enable an answer to be sent to inquiring members.

A letter was read suggesting that the Association, after incorporation, should endeavour to secure that professional photographers, when called upon to give evidence in courts of law, should have a proper fee. It was suggested that the photographer should make his bargain with the solicitor before consenting to give evidence. One member of Council said that he had been paid three guineas a day in the High Courts, but it was necessary that the photographer should make his bargain beforehand, though, of course, this could not apply in the case of a subpœna.

Mr. Speaight presented the Congress balance-sheet.

Mr. Brown proposed, and Mr. Watson seconded, a vote of thanks to the treasurer and those associated with him in the financial arrangements, and congratulated him on a satisfactory result. A further vote of thanks to Mr. Speaight was carried for placing his studio at the disposal of sub-committees engaged upon Congress work. Mr. Adams was also thanked for his work in arranging the Exhibition.

The secretary reported that the Finance Committee had met and recommended for payment various accounts amounting in the aggregate to £192 3s. 6d. The recommendation was adopted.

Mr. Corbett proposed, and Mr. Speaight seconded, a vote of thanks to the editor of the "British Journal of Photography" for his excellent reports of the Congress proceedings, and this was agreed to. It was also agreed that the thanks of the Association should be sent to the various lecturers, to the Imperial Dry Plate Company for the loan of glass for pictures, and to any others who had assisted in the Congress arrangements.

The chairman said that the draft Articles were before the members of the Council, and would require very careful consideration. It was impossible to take this business, he believed, at any ordinary meeting, and he suggested that the members look through their copies, and send their comments to the secretary within a week or so, and that a special meeting of the Council be called for a fortnight from that day.

Mr. Frank Brown and others thought that another meeting of the Council within a fortnight would bear hardly on the country members. Eventually it was agreed to have a preliminary committee meeting to thrash out certain matters in advance, that members should send in their comments to the secretary by May 25, that the sub-committee should meet within a fortnight to prepare matters for consideration by the Council, and that the matter be brought before the meeting of the full Council on June 10.

The Committee for this purpose consisted of the following:—Messrs. Adams, Basil, Haines, Hana, St. George, and Wakefield, and the officers. It was agreed that the meeting should be held on May 27 at 4 p.m. at Mr. Speaight's studio.

Mr. Corbett moved in the name of Mr. Chidley a resolution that the secretary be instructed to make inquiries for the best Press Agency in London and their terms, with a view to making similar arrangements with such agency as had already been made with a certain company in the matter of insurance. Mr. Chase seconded.

After some discussion it was agreed that the matter should be put on the agenda for the next meeting.

It was agreed also that various suggestions remitted from the annual general meeting should be placed upon the next agenda.

It was further agreed not to publish another number of the "Circular" pending new instructions from the Council.

The Council then rose after a sitting of three hours.

News and Notes.

THE THURLOW MANUFACTURING COMPANY is the new title of the business formerly carried on as George S. Moore, at Denmark Hill, London, S.E.5, and specialising in strip-printing apparatus, etc. The Thurlow Company now carries on its business at Thurlow Street, Walworth, S.E.17; telephone number, Hop 3194.

TECHNICAL PERIODICALS.—Messrs. Henry Sotheran and Co., 140, Strand, London, W.C.2, have just issued a 56-page list of sets of scientific and technical periodicals which are offered for sale by them. The collection includes a large number of chemical and other scientific journals, and also a number of "runs" of photographic journals, among which are the "Photographic News," "British Journal of Photography," "Camera Obscura," and Eder's "Jahrbuch."

FLORA DEVELOPING DISHES.— In reference to a recent query, Messrs. Jonathan Fallowfield inform us that the Flora dish was formerly made by Messrs. Taylor, Tunnicliffe and Co., of Hanley, Staffs, but that its manufacture has long been discontinued. Messrs. Fallowfield can offer a few dishes of the whole-plate size at the price of 2s. each. These dishes are specially designed to enable two plates to be developed in the same quantity of solution as a single plate.

AERIAL SURVEY.—In connection with the surveys, which are being carried out in the Canadian North-West Territory by the Imperial Oil Co., aeroplanes are to be employed fitted with cameras for the purpose of obtaining photographic records of water courses and other features of the landscape of importance in the transport of labour and equipment. The photographs will also be of value to surveyors and others in mapping out the country without the use of the customary topographical methods.

LUTE FOR BOTTLES.—In reply to an inquirer for a composition for capping bottles, the following formula is given by the "Pharmaceutical Journal":—Gelatine, 1 oz.; gum acacia, 1 oz.; boric acid, 20 grs.; starch, 1 oz.; water, 16 fl. oz. Mix the gelatine, gum acacia, and boric acid with 14 ozs. of water, stirring occasionally until the gum has dissolved. Then heat to boiling, remove any scum, and strain. Mix the starch evenly with the rest of the water, mix with the gelatine solution, and heat until a uniform mixture results. Add any desired colouring, and pour to set in suitable bottles. When required for use, melt with gentle heat, and immerse the corked bottle in the warm mass. Zinc oxide may be incorporated with the above.

PICTURE-HANGING WIRE.—Mr. R. B. Marston writes to last week's "Nature": Some ten years or so ago I was advised to use twisted brass wire of five strands, which was then immensely strong, with a breaking strain of probably more than 100 lbs., but it has become so rotten as to break under a weight of a pound or two. This wire has been in use in a very dry room with electric light only. My own experience has proved that plain copper wire in one strand has lasted three times as long as the twisted brass wire, though bearing far heavier weights. Before the war a "wire" consisting of a steel core with some other wire braided over it was recommended, but it is soon affected by rust, and appears to be much stronger than it really is.

PHOSPHORESCENT PRINTS. — A recent patent specification, No. 160,739, not yet accepted, of J. H. Christensen, relates to a process for reproducing prints or photographs by means of a phosphorescent medium in which the action of red light in destroying the phosphorescence of the medium is utilised. The transparent phosphorescent screen or sheet is placed in contact with the print or photograph and illuminated or acted upon by coloured light. The sheet is subsequently placed in contact with a sensitive film to produce an image of the print or photograph. The translucent phosphorescent sheet may be coloured or the phosphorescent medium itself may be coloured. In preparing a translucent sheet the phosphorescent material is comminuted by mixing it with liquid and shaking it up with glass balls. The comminuted mixture is mixed with gelatine and glycerine and poured on to a glass plate covered with a film of rubber. After the phosphorescent material has settled and the film solidified, a coloured collodion coating is applied and dried, after which it is stripped and the phosphorescent surface exposed to strong light to render the material active.

Correspondence.

QUADRO PASSE PARTOUTS.

To the Editors.

Gentlemen,—We are very much obliged to you for your reference to "Quadro" frames in the article "Passe-Partouts for Specimens" under the heading "Ex Cathedra" in your issue of May 20.

If we may venture to do so, we would call attention to the additional advantage that, whereas, in cases of breakage, a frame of ordinary paper passe-partout binding is irretrievably damaged, with the "Quadro" frame it is only necessary to replace the glass.

We shall be delighted to send a sample of frame to any photographer who cares to write one and will mention the colour desired. You are probably aware that we produce in black, brown, and grey, and, for coloured pictures, in gilt.—Yours faithfully,

BARTONS' (BIRMINGHAM), LTD.

Cosway Works, Finch Road, Handsworth, Birmingham.

PARTIAL REVERSAL BY WHITE-LIGHT DURING DEVELOPMENT.

To the Editors.

Gentlemen,—Whilst developing a batch of snapshots of some steeplechases, when the negatives were about half-made an assistant accidentally switched on an electric (white) lamp over the dish containing the plates. The light was extinguished very

quickly; the result, however, was a freak, half negative and half positive. I enclose a print from the same.

It is the first time in 35 years' practice of photography I have seen such a result.

M. COOPER.

29, East Street, Taunton.

INTERESTING THE SITTER

To the Editors.

Gentlemen,—The rather caustic comments of your unsophisticated correspondent "35 Years a Professional Photographer" are most refreshing after the rather "high falutin' talk" we have had from and about lady photographers. As regards this widely-published "talk," I am of opinion that the statement made by one woman worker: "It is so easy to descend to the level of the sitter," calls for some explanation.

Does it mean that those who go to lady operators are of inferior intelligence, and that conversation has to be brought down to a sitter's level? And that after discussing French maids and the latest Parisian fashions with the dames of Balham and Upper Tooting, the lady photographer can say with perfect naturalness, and better than a man: "Oh! bli me, your fever is a treat. Not 'arf!" when Arry calls in from the East End to have her "photo took"?

I am reminded of a story of J. L. Toole—who was a good friend to photographers—who, after accepting an invitation to dine with Gladstone, found the company at table to consist of about a dozen of the leading literary and other celebrities of the day. Toole, in telling the story said: "They discussed German literature, old china, and dozens of other things I knew nothing whatever about, and the first thing I did after making my escape from the party was to find a policeman and have a gossip with him in order to find my intellectual level."

Women are renowned talkers, it is true, but not necessarily good conversationalists, and I cannot imagine any one of them in a studio interesting a man with intellectual talk such as a really good man operator can do. An experienced man operator's talk, when it is called for, may—to quote Dr. Johnson—"not always show the

minute-hand, but it strikes the hours very correctly," and, after all, customers do not attend a studio for idle twaddle.

Women photographers are merely a passing fad of a fickle populace, and as much out of place in our community as women barbers and police. But we shall have to endure them for a time, just as we have to put up with influenza and rheumatism. If we have patience, the whirligig of time will bring its revenges upon them and compel them to play the part in life Nature intended them to do, and nurse babies rather than grievances about whiskers.

A lady photographer will never have the courage to remain in the business for long, or to advertise her "many years' experience," and "35 Years a Professional Photographer" can continue to jog along (with his whiskers) in his old sweet way, and may rest assured that no woman photographer will ever be able to truthfully use his honoured nom-de-plume.—Yours faithfully,

ONLOOKER.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. W.—We know of no book dealing with the making of hand-cameras. You can buy brass and woodwork from the Photographic Supply Co., Shepherd's Lane, Leeds.

E. N.—There are processes of reversing a negative on bromide paper, but from a somewhat extensive experience of them we think we can say that none of them are reliable for regular use. Certainly none of them are as economical in use as making a positive transparency and a negative again from that.

M. W.—Kathol is one of the metol substitutes sold in America. No doubt it is still obtainable from any general dealer in photographic requisites, such as Messrs. George Murphy, 57, East Ninth Street, New York, but we think the formula would work just as well with any of the metols which are on the market in this country.

R. F.—There is no easy way of regilding frames. It requires a considerable amount of practice to get the even surface you require. The surface of the old gilding must be carefully smoothed, then a coat of special size applied, and when this is just tacky, gold leaf is laid on, and pressed gently down, if necessary, with a camel-hair brush and cotton wool. There are two systems, water gilding and oil gilding.

W. A.—(1) Nothing better than "Bildup," of the Vanguard Co., Maidenhead. (2) We are afraid there is no means of removing mountant stains without affecting the glaze. You might try a little pure spirits of wine rubbed on with a soft rag, but anything containing moisture will remove the glaze. (3) Dilute the varnish with a little boiled linseed oil. (4) If perfectly dry, papers and plates will suffer little damage by heat, but as usually they are not thoroughly dry, the effect of any damp is greatly aggravated by heat.

R. R.—The formula you require is on the lines of that given below:—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs.
Liq. ammonia .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined by daylight and fixed in plain hypo.

G. K.—There has been scarcely any literature on the making of Autochrome transparencies for several years past. Actually the very complete booklet of instructions issued by the British representative of MM. Lumière, Mr. T. K. Grant, 89, Great Russell Street, London, W.C.1, is the best instruction manual there is. There is certainly a great difference in the density of Autochrome lantern-slides, but the only "formula" that we know of for getting a clear, brilliant slide is exactly the right exposure of the plate in the first instance. Usually Autochromes for projection can do with just a touch of intensification in order to increase their brilliance.

R. T.—The following is a suitable formula recommended by Messrs. Houghtons for delevoper for quantity development of amateurs' films:—

Pyro	12 ozs.
Sodium sulphite (cryst.)	7½ lbs.
Potass. metabisulphite	15 ozs.
Sodium carbonate (cryst.)	3 lbs.
Potassium iodide	50 grs.
Water up to	10½ galls

The following instructions *must* be strictly followed, as the keeping qualities of this developer depend entirely upon the method of making up. Dissolve the sulphite in two gallons of hot, but *not* boiling, water. When dissolved add the metabisulphite, and then boil for five minutes. Cool down to about 70 degrees Fahr. and add the pyro. Dissolve the carbonate in one gallon of warm water, then add the iodide. Pour these two solutions into the tank, and then fill up with water to the top as usual. The most satisfactory temperature for developing is 65 degrees Fahr., and it should not be used below 60 degrees. When the developer is first made up, the time of development at 65 degrees is about eighteen minutes.

After the developer has been used for two batches, it will be necessary to strengthen it with every batch. The strengthening solution is made by dissolving the chemicals given in the following formula. Exactly the same methods must be followed as when preparing the first developer:—

Pyro	½ oz.
Sodium sulphite (cryst.)	5 ozs.
Potass. metabisulphite	5 drs.
Sodium carbonate (cryst.)	15 ozs.
Potassium iodide	8 grs.
Water up to	120 ozs.

As regards your fixer, no wonder it gets into a milky state, if you are simply adding acetic acid to plain hypo. You should make up the fixer with sulphite or metabisulphite according to the acid fixing formulæ in the "Almanac," for example, or in the directions given by almost every maker of gaslight paper.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3187. Vol. LXVIII. FRIDAY, JUNE 3, 1921. Price Fourpence.

Contents.

SUMMARY.

In a contributed article Mr. D. Charles describes a number of recent experiments on halation, and endeavours to single out the factors among subject, plate, lens, exposure and development which are of chief importance in the prevention of this defect. (P. 323.)

The revised formulæ due to Mr. F. Garon for the Carbro printing process will be found on page 327.

In a leading article we seek to trace the psychological processes involved in the effective influence upon passers-by of a display of portrait photographs in the customary showcase. (P. 322.)

Formulæ for two further developers having a desensitising action on the residual emulsion have been recently given by Dr. Lüppo-Cramer. They are made up respectively with paramidophenol and glycin, in each case with phenosafranine. (P. 321.)

In the concluding portion of the article on electrical facts for photographers the writer deals chiefly with the running of arc and half-watt lamps. (P. 326.)

A correspondent raises the very interesting question as to whether, if studios and workrooms are exempt from the Shops Act, employees in these departments of a photographer's business can claim the benefits granted by that Act. (P. 331.)

The death is announced of Mr. I. F. Hammer, for many years a maker of dry-plates in the United States. (P. 330.)

A method of making a cardboard carrier for plates of smaller size than those accommodated by the full-size dark-slides of a camera will be found described in a note on page 322.

" COLOUR PHOTOGRAPHY " SUPPLEMENT.

Lt.-Commander H. E. Rendall, in some notes on the Raydex colour process, has a number of hints to give on practical points of manipulation. His article (P. 21) usefully supplements the official instructions of the Raydex Company.

The unfortunate experience of Du Hauron and of other inventors in the field of colour photography leads us to warn the ingenious of the somewhat remote chances of profiting in a substantial financial form from inventions in colour photography. (P. 24.)

Methods of securing full rendering of clouds in the Autochrome are the subject of a paragraph on page 24.

Patented processes for dye-toning in its application to the making of colour prints have been prominent of late. Mr. W. Van Dorn Kelley has claimed a copper-chromium bleach (P. 22), Dr. Traube has returned to the subject by describing a bleach compounded of copper salts for use with certain dyes (P. 23), and a further patent, with which the name of the late W. Friese-Greene is associated, describes a somewhat complex mixture containing both dye and bleach. (P. 23.)

Some notes on lighting and exposure in Autochrome work will be found on page 22.

EX CATHEDRA.

The Royal. The Royal Photographic Society announces the date of its sixty-sixth annual exhibition, viz., September 19 to October 29 next. The exhibition will again be held in the Society's house, 35, Russell Square, London, W.C.1, and admission will be free. The prospectus and entry form will be ready shortly, but in the meantime the following provisional particulars may be given. In the Pictorial Section the judges will be Messrs. Marcus Adams, Bertram Cox, J. Dudley Johnston, F. J. Mortimer and Hector Murchison. The section for colour transparencies and prints will this year be divided into a pictorial and a technical sub-section, an innovation which has long been needed and which will simplify the judging of these exhibits. In the pictorial sub-section the judges will be Messrs. F. T. Hollyer and W. L. F. Wastell. In the technical sub-section the work will come before the judges of the main scientific section, viz., Messrs. Charles R. Davidson, J. Willis Grundy, Hugh Main, Dr. Robt. Knox, and Dr. G. H. Rodman. The hanging of the exhibition will be undertaken by Messrs. G. Bellamy Clifton, C. P. Crowther, J. B. Portway, and T. H. B. Scott.

* * *

Safranine in Developers. In the current issue of "Photographische Industrie" Dr. Lüppo-Cramer gives two further formulæ for developers containing safranine, and thus serving for development by bright yellow light owing to their desensitising action. The first developer of this form, viz., paramidophenol, is made up by dissolving 50 gms. potass metabisulphite, 20 gms. paramidophenol hydrochloride and 1 gms. potass bromide in 125 c.c.s. of water. To this is added with the customary precautions a solution made by dissolving 70 gms. pure caustic potash in 90 c.c.s. of water. Much heat is developed in dissolving the potash and the solution must first be cooled before adding to the first. To each 200 c.c.s. of the mixture, 10 c.c.s. of 1:100 phenosafranine solution is added. The dye is precipitated, forming a turbid mixture. The latter, therefore, requires to be well shaken when making up the working developer by mixing with about twenty times its bulk of water. For a glycin-safranine developer 50 gms. of potass metabisulphite and 20 gms. of glycin are first mixed together in a good sized vessel. Potass carbonate (200 gms.) is then added and addition made in small doses of 180 c.c.s. of water. In this way a thin creamy mixture is obtained of bulk about 250 c.c.s., to which is added 25 c.c.s. of 1:100 safranine solution. In this case also the dye is precipitated, but redissolves on dilution of the cream, to form the working developer, with 10 to 15 parts of water. If the glycin developer is to be used at a greater dilution for slow development the proportion of phenosafranine should be correspondingly increased.

Plate Carriers. There is often a difficulty in obtaining carriers for plates which are very slightly smaller than the slides in which they have to be used, for example, the half-plate in a 7½ x 5 or the 9 x 12 cm. in a 5 x 4 slide. It is, however, quite easy to make cardboard carriers which answer the purpose perfectly and which will stand a fair amount of wear, by using a thin card as a foundation and building up the margins. In the case of 7½ x 5 to half plate, we start by cutting a thin hard card, or even a ferrotype plate, the full size of the slide. The next step is to cut strips of card or very thin wood a shade thicker than the plate, which are fixed upon the card so as to form a cell into which the smaller plate will fit. At one of the ends is glued a strip of veneer overlapping one-sixteenth of an inch, and at the other end two small brass buttons riveted through with ordinary brass boot rivets. The heads of these rivets should be at the back of the large card, and the ends cut off and riveted on the buttons. If wooden strips be used very tiny screws may be used instead. An alternative plan is to use a thin cut-out card in front and to have one of the end slips movable so that the plate may be slipped in as a print is fixed in a cut-out mount.

PSYCHOLOGY OF THE SHOWCASE.

PRACTICALLY every photographer uses either a window or a showcase for displaying his work, and often the showcase is the only form of advertisement resorted to, either because the worker does not believe in window display, in connection with a studio, or if he does, he may not be fortunate enough to possess a window, owing to the construction of his premises. That publicity pays must be admitted, as we live in an era of advertising at the present time. A photographer's showcase is either a good advertisement or a bad one, and if neglected at once irritates the "public eye" and does more harm than good, while a well-planned display is a remunerative advertisement, bringing custom to the studio. Naturally, every display is of the worker's best ability when it is first arranged and put before the public, but how many *neglected* showcases we see about our towns to-day! When new, no doubt they did the worker great credit, but owing to neglect they are bad advertisements. The firms they represent may turn out real good work in every way, but strangers look at these showcases and judge the firm accordingly. It would be far wiser to rely upon "work turned out" than to own an unattractive advertisement. What is an advertisement? It is an announcement. A photographer's showcase announces something. It tells the public where the studio is situated and, above all, the class of work turned out. Hence the importance of making it a good advertisement and creating a good impression. Let us now go one step farther and think of the "elements," so to speak, of good advertisements. The chief points of a good advertisement may be summed up under four headings, as follows:—

1. It attracts.
2. It holds interest.
3. It creates desire.
4. It impels action.

These four points are based upon sound psychological facts. They act upon the mind. Let us now deal with each point separately as applied to our photographic showcase display.

As regards attraction, the first consideration should be "position." Usually the showcase is fixed at the studio entrance, and great care should be taken to use the best space for publicity. Sometimes a case on one side wall of an entrance may be passed almost unnoticed, while one on the other side may instantly attract the eye, on the same principle that a shop one side of a street may have a far more valuable position than a shop directly "opposite" in the same street. If a showcase be tried first on one side of an entrance for a short time and then changed to the opposite wall for the same length of time, a striking difference will be noticed in the number of people attracted to look at the display in each position. This point, of course, is only considered with displays inside the doorways, when there is no space available facing the street. The position, then, can be chosen according to its power of attraction. Then comes the question of height. The showcase should be at a convenient "viewing" height, so as to need no undue effort to view the display. Another feature to consider is lighting. If artificial light is required it may be either from the general light in the studio entrance or even lighted by miniature lamps fitted inside the showcase itself with a switch in some convenient place. Even in daytime, if the entrance is dull, it pays to keep the showcase lighted artificially, the main point being that "light" attracts.

Having attracted anyone to notice the showcase, what will hold their interest? If, on approaching closely, the display is found to be untidy or inartistic, the interest is not held, so the first thing should be an artistic case both inside and out. This does not necessarily imply an elaborate design; in fact, one, rather simple and well balanced. The backboards should be subdued and of good appearance. Art boards or canvas—in fact, endless varieties of material—can be used at little cost, to cover the backboards forming a ground for the prints. Some high-grade wall coverings cannot be beaten for effect, these, of course, being of the self-coloured variety, art shades or imitation canvas, etc. Now a word about the selection of "specimens." These should be interesting and topical. A recent wedding group, portraits of local celebrities, popular sports, concert or committee groups, all "hold interest." It is a very good plan to change not only the photographs but also the scheme of showcase dressing. The photographer of average artistic ability will have no trouble in devising fresh ideas, and anyone having noticed the showcase on a previous occasion is "attracted" by the change and interest is immediately renewed.

The creation of a wish obviously relates to the specimens on show. They should be carefully chosen, not only for quality but also for their suitability to the display. Taking it for granted that we have a number of good prints, the final arrangement should be well balanced as regards sizes, mounts, colour, and general key of effect. For instance, one display may be solid dark background work, while a change could be made to light vignette and sketch or coloured styles, the former being in a low key and the latter in a high key, with suitable case-dressing schemes to each in turn. Such arrangement of well-selected prints will be pleasing, and the desire is created to have portraits taken in the styles and processes shown because they are distinctive. "I want something like that," is what a customer thinks on seeing a pleasing style. Something distinctive—just the bit different from all others. To be distinctive one must show personality in his work, some power and character. This all creates desire and, which leads us to our fourth point, impels action.

What has been the process of our advertisement so far, step by step? First, to attract clients by the power of publicity. Secondly, once attracted, their interest has been held by the pleasing arrangement of display. Thirdly, being pleased, they desire to have something

like that which pleased them. Having the desire, they are naturally impelled to action—to make an appointment for a sitting. So, right from the start, one point leads on to the next, and that should be the chief aim of an advertisement. The four points we have studied in detail act upon the mind subconsciously and instantaneously, but if a sitter says to you, "I came to be photographed because I liked the pictures in your showcase," it is certain that person's mind went through the process we have analysed. In conclusion, if a public display of work is neglected the whole process is reversed and the bad advertisement is a vital danger to business, driving away instead of attracting custom. A little study of "psychology of the showcase" is well repaid.

PREVENTION OF HALATION.

Recent correspondence shows that the causes of halation are not yet thoroughly understood. Each writer has his own pet theory as to what gives rise to this trouble, and how to avoid it, yet expresses surprise that apparently opposite methods and conditions do not exhibit the annoying feature.

The truth is that there are many causes, and halation will not be obtained unless (as a rule) more than one of these is present. May it be said without giving offence that the apparently miraculous instances given of supposed halation-inviting subjects do not at all impress me, not because I have any claim to absolute immunity from halation in my own work, but because I have been able to make some amount of practical investigation of similar subjects, and have thereby been able to avoid the trouble completely in cases where the "invitation" has been considerably more pressing. It must, I think, be conceded that there are still cases in which halation cannot be entirely avoided, but even these rare cases can be handled so that its presence may be unnoticeable by any but the hypercritical.

To begin with it is necessary to make some definition, such as to state that by halation I mean any spreading of light around any portion of the image, and irrespective of scientific subdivisions, and by correct exposure I mean such exposure as will render a satisfactory amount of shadow detail by ordinary methods of development followed by printing on my favourite printing medium. That is to say, I propose dealing with the subject from the practical photographer's point of view with a reasonable amount of latitude of terms, so that I hope no one will want to quibble with me on points of definition, so long as the conclusions of my arguments are agreed to. For instance, when I state that I find halation difficult to obtain, I know perfectly well that it is quite easy to obtain by placing a plate in contact with a sheet of black paper in which there are some pinholes and exposing the same to a source of light for sufficiently long. The image of each pinhole will be surrounded by halation more or less defined according to the degree of diffusion of the light and the nature of the emulsion. What I mean by difficulty of obtaining halation is the difficulty of getting it in the camera, on subjects of quite "inviting" a character, when using my favourite plates and lenses, whatever developer I may use, or whatever its degree of dilution.

In that last sentence all the factors have been stated.—The subject, the plate, the developer, and what is so seldom suspected, the lens. In my opinion, when a bad case of halation occurs it is never due to one of these factors alone, and generally can be traced to more than two of them being present so that by noting the conditions of each of those factors it becomes possible in many cases to avoid the combination of circumstances which are likely to accentuate the trouble.

Of course it is the subject that usually is considered to be the principal source of halation, but beyond the very elementary proposition that without a subject one would be entirely free from the fault I am compelled to say that in a very great number of subjects which would seem to be predisposed to halation there is not the slightest sign of it, and where a worker finds the undesirable feature occurring frequently in such subjects he will usually find it also, though less pronounced, of course, in his general output. The kind of subject that is supposed to be "difficult" from the halation standpoint is naturally one with abruptly marked contrasts, such as an interior which includes windows in the view photographed, a nude sitter in evening-dress, and especially subjects which contain artificial lights whether diffused or unscreened. When surprise has been expressed at the absence of halation, or when merit is claimed for any special material or method it is always in connection with such subjects, but I wish to point out that although these do often exhibit the trouble in question it is comparatively few cases in which it is not preventible. It is obvious that a variety of subjects prone to halation contains detail in the high-lights comparatively over-exposed when compared with the detail in the shadows. That is to say, that if one were photographing those high-lights alone a fraction of the exposure given to ensure satisfactory rendering of the shadows would be sufficient. For instance, a large machine may contain black castings in shaded parts, while in a prominent position as regards light may be a dial consisting of white card bearing fine black lines (a volt-meter or pressure-gauge). If one were photographing the dial alone a quarter of normal (*i.e.*, meter reading) exposure would suffice, yet it is likely that six times the normal will not be overmuch for the black details. Therefore, the dial will have received quite twenty-four times the exposure that one would give it alone, and if any halation were present it would certainly obscure the fine black figures on the dial. Such a case as this is quite usual in the experience of every commercial photographer, who obviously cannot follow the advice of a correspondent who recommended that one should not expose so that any detail should penetrate the emulsion. He would be a fortunate man who could limit himself to subjects that did not compel him to do otherwise. It is not suggested that in a case such as the one described the dial will be rendered as clear and brilliant as though it had been taken by itself, but the writer has in his possession quite a number of such photographs in which the machinery is quite fully exposed and in which the dials can be read (with a magnifying glass in some cases) although the black lines in the photographs must be less than a five-hundredth of an inch in thickness. This description of subject is actually a greater test than the instances so often quoted of detail photographed against the light of factory windows. If these supposed remarkable instances are analysed it will be found in a great many cases that the difference between the exposure required for the subject itself is not greatly in excess of that needed for the view through the window if the latter were photographed with a dirty piece of glass in front of the lens as in the actual case in point. If, however, the subject be photographed against a window which is itself the only or, at any rate, the main source of illumination the case is very different, as the light which reaches the side of the subject facing the camera obviously is far weaker than the direct light shining in the lens, and the disproportion between the exposures that would be sufficient for the subject or for the window or view outside it are infinitely greater than in the examples suggested above. The disproportion is even greater than in subjects in which the source of illumination (whether

day or artificial light) is included, but arranged in a more normal way. What I am aiming at explaining is that the only sort of subject in which halation may be said to be inevitable or excusable is that in which not only is there a source of illumination but in which also that detail is over-exposed by some hundreds of times. Even then it will be found that if the other factors are favourable the halation can often be confined mostly within the illuminated area itself, and it will not be noticeable except in the rebate of the negative. The writer was asked recently to photograph a subject which might seem the very limit as regards halation-inviting. A network of wires, the latter less than a sixteenth of an inch thick, was suspended seventy-five feet above the ground, and further wires connected this arrangement to the earth. The whole was about a hundred-and-fifty feet in length, so that on reducing the subject to whole-plate the thickness of the wires could be seen on the ground-glass only as a very faint grey hair-line when examined with a powerful focussing-magnifier. The difficulty of the case was not diminished by the fact that the supports had to be rendered upright, so that a somewhat distant standpoint had to be taken and the axis of the lens was necessarily neither central nor square with the plate. In addition to this, the wires were moving slightly in the wind. Yet it was found possible to obtain a perfectly sharp map-like photograph of the wires, and in a couple of plates the surrounding landscape, both foreground and distance, was quite satisfactorily rendered also.

Being of an experimental turn of mind, and wishing to test my theories as well as those raised by various correspondents, I arranged a test subject intended to include all the problems likely to give rise to halation. A half-watt lamp of three-hundred candle-power was hung so that the etched lettering on it faced the camera. A large focussing-screen was supported in front of this, so that one of the sides of the wooden frame cut the image of the bulb but left the other half clear. On the ground-glass (which was only a few inches from the lamp) two negatives were fixed with lantern-slide strips, one a line and one a tone subject, still leaving part of the ground-glass clear, and some scratches were made in both negatives. Still further complications were introduced by shading half of this arrangement with a thickness of tracing cloth, and by sticking overlapping strips of translucent paper on the edge of the wooden frame. Close to the unobscured half of the lamp was arranged a group of objects that normally would be considered not an easy subject, taken as a whole, to photograph, ranging from a piece of cotton wool and a graduate half full of water to a bottle of Azol. A sheet of ground-glass, to reduce the intensity of the light, separated this group from a similar set, which, however, contained even darker objects. To add to the "difficulty," I pinned on the wall at the back a sheet of printed matter, this extending from the least illuminated portion to immediately behind the bulb itself. Thus the subject could be considered to consist of a very powerful direct light, as well as brilliantly illuminated "windows" of many shapes, sizes, and densities, many of them overlapping one another, as well as details of such nature and in such positions that if serious halation occurred they would be lost. Quite a number of plates were exposed upon this subject, both backed and not.

The plates were of two makes and of three varieties. It was found that with the stop which was used throughout an exposure of three seconds on a backed ultra-rapid plate gave not only a perfect rendering of the bulb with all the details immediately adjacent to it, but also everything else except the very faintest shadow gradations. Printed with care on a contrasty paper, this gave a very fair reproduction of the whole, and a quite perfect result of the lighter portions. There was no halation, except faintly round the filament itself, though there was a little diffraction in the form of a few tiny lines radiating from it across the wooden bar previously referred to.

All the plates used were about the same speed, and the exposures given ranged from the three-second one to three times as much, then forty times, and finally two-hundred-and-fifty times the original exposure. Of the latter four plates were exposed and developed in different ways and with different developers. Regarding the amount of halation, it may be said at once that in proportion to the detail image—that is to say, as seen in the prints—there is very little difference between any of these greatly varying exposures. What little there is, is only to be seen immediately around the lamp; and in all the negatives, and most of the prints as well, every detail of the lettering on the bulb is plainly readable, and very little of this is lost on any of the prints. The filament itself is, of course, reversed on all excepting the first three-second plate.

The modes of development were as varied as the exposures. For instance, two similar plates, both unbacked, were exposed for two minutes each, and developed in M.Q., but in one case the developer was used in concentrated form, and for the other was diluted so that the plate took ten minutes to develop to equal density. No difference could be detected. As a matter of fact an enlargement was made from the slowly-developed one to the size of the original subject, and in this the gradation throughout is distinct, from the detail in the bulb itself to the darkest shadows. The line subject can be plainly read even in the part of it that is seen through the glass of the electric lamp, and the writer was complimented on the quality of the texture of the details by one whose familiarity with photographs must be such as normally not to arouse any enthusiasm. In this case the bulb was over-exposed by forty times, and the other parts of the subject by six or eight times, and the plate was unbacked and softly developed. Of the plates which were exposed for over six times as much again as this one, one of them was unbacked and was of slightly greater speed. This "impossibly" over-exposed plate was developed in Azol of such dilution that at the end of an hour it had not attained printing density, so was finished off with a little stronger. There is actually no more halation in this than in any of the more normally treated plates and none in the "windows," and although the "quality" of the gradation naturally is poor no detail is lost anywhere. Of the backed plates similarly over-exposed, and developed normally for four minutes, prints show the best quality and gradation of any, though they are, of course, so dense as to make enlarging from them an utter impossibility.

I do not propose to argue from this that any exposure and any method of developement will not bring out halation, but it does prove that if one uses plates that are reliable, it seems to matter little how one treats them. I would suggest to anyone who is frequently troubled with halation to ask himself if he ever congratulates himself on the rapidity with which his plates fix out. I think it will be found that a plate which is liberally coated with emulsion, and which therefore fixes slowly, will be found far less prone to halation in any circumstances.

It is a fact that in the case of plates which do give halation rapid development with a normal developer, or one slightly stronger and *not cold*, will reduce this liability. In proof of this a client who had been trying his hand at outdoor night-scenes complained to me of the intense halation round every street lamp. I asked him how he developed? The answer, "Tank." On my recommendation he tried rapid development, and had entire success with the same make of plate. There is no difficulty about this if one employs the time-and-temperature method. Having developed a trial plate of a trying subject, at say, 70° by judgment, but noting the time, it is easy for any experienced photographer to decide whether for the future he will develop such subjects for a longer or shorter time, and to make a rule of doing so at that temperature.

Now I come to the last of my list of halation-giving factors, namely, the lens. And in writing this I can visualise the smile of derision on the faces of some of my readers. Yet I am of the opinion that, next to the plate, the lens is more often the cause of provoking halation than any of the other factors. This opinion is the result of experience in many carefully noted cases. While not pretending to any theoretical

knowledge of optics, I think that the way in which a lens produces halation of a brightly-illuminated area is by the images of such details being reflected from one surface of the lens to another, and such reflected images being still powerful enough to be projected by the lens along with the normal image, but not quite coinciding with it and, of course, very much out of focus. Besides this there is a certain amount of flare, or diffused light, produced by every lens when a brilliant subject is being photographed. It is well known that single lenses are the least liable of all to this sort of trouble, but the occasions on which they can be used are so rare, on account of defects in other respects, that they are ruled out by the practical photographer. Of lenses in general use I have found anastigmats made to work at a maximum aperture of *f*/8 most satisfactory as regards freedom from halation in results. It is not at all difficult to make comparative test of lenses as to their qualities in this respect without actually exposing any plates. The way to do this is to arrange a movable light of fairly large area, such as a lamp of any sort with a sheet of tissue paper or ground glass in front of it. Then, having focussed the camera on a subject containing some darkish details, not too brightly illuminated by some other light source, examine the image with a focussing magnifier, and, while doing so, get an assistant to bring the bright, movable light so that it comes into the field of view and away again, and note whether the brilliance of the detail examined is affected or not. If it is seriously affected, it is obvious that such a lens calls for the use of a hood when used on any subject in which any bright area is likely to shine in the lens, and should be avoided altogether for such as actually include brilliant portions. Even without going to such trouble as this it is surprising how the probability of halation is revealed by the use of the magnifier. For a considerable time I was worried with a distinct thickening of fine, white lines in a certain description of dark subjects. This was when employing either of two lenses I had then in use, and was shown both in making original or reproduced negatives of the kind of subject referred to though both appeared to give good definition otherwise, and I then attributed the fault to halation in the plates, but on trying a new anastigmat on the same plates was agreeably astonished to find the trouble vanish.

Another instance which will illustrate my point is when using a lens for enlarging, more especially in apparatus in which a condenser is used. When a dense negative is being enlarged from which a clear area is included, or when the clear rebate is projected, the developed image often will be marred by any such black portions being diffused on to the surrounding surface. This has been attributed by some to dust in the air, to "spread" in the emulsion, to anything but the actual reason. Yet if a really high-class lens be installed, and, still better, if the condensing lens, with its deep curves and optical faults, be done away with in favour of a reflector arrangement, the trouble referred to will vanish.

To sum up I think it may fairly be stated that provided one employs plates of a kind that is thickly coated with emulsion, and is backed with a really efficient backing, and one uses lenses (well hooded when possible) that show on actual trial to be free from flare, one may tackle the most extreme cases of "halation-invitation" with a care-free mind, and without taking any special measures as regards development. It may be added, however, that cases of apparent halation have been traced, in my own experience, to poor black on the inside of camera bellows, to dust or condensation on the lens, and in one case at least to faulty balsam in one combination of the lens. This defect was visible only on holding the lens up to a small source of light and looking through it in a slanting direction. It was then seen as a faint veil, but it had a very noticeable effect on the images of any bright points in the picture. Lenses should not be judged, in respect of the trouble mentioned, by their price or by the maker's name, nor by any theory as to any particular type of lens. The only way is by actual practical test of the individual lens.

D. CHARLES.

ELECTRICAL FACTS FOR PHOTOGRAPHERS.

(*Concluded from page* 314.)

WHERE alternating current arc lamps are used great economy can be effected by the introduction of a transformer, or a choking-coil, though this is apparently unknown to some photographers, as the writer knew a man who, having fitted up his own lamps, had run them for some years on an alternating supply with only a resistance in circuit, the consequence being that his electricity bill was more than doubled. Transformers differ in design, but the principle on which they act is the same. The separately-wound type consist of two coils of insulated wire wound on a laminated iron core. One coil, the primary, is connected to the supply main, and, on an alternating current flowing through it, an "induced" current is caused to flow in the secondary coil.

The voltage of the secondary coil is proportional to the ratio of the number of turns in the two coils, so that it is possible either to decrease or increase the voltage of the secondary. For arc lighting the former is almost invariably the case, the volts being brought down to about 50 for one lamp.

Great care should be exercised when connecting to the mains that the proper terminals are wired, or a dangerous accident may occur. If, in the case of a 200-volt supply with a secondary pressure of 50 volts, the secondary terminals were inadvertently connected to the mains, it is possible that the four-to-one ratio would result in a pressure of 800 volts being developed. In addition, the transformer would almost certainly be burnt up.

The higher the supply voltage the greater is the economy effected, as will be seen from a simple illustration. Assuming the supply to be 240 volts, and the arc to take 10 amperes, with only a resistance in circuit the consumption would be 2,400 watts, or 2 2·5 units per hour. By transforming the pressure down to 50 volts the consumption would be reduced to 500 watts, plus a small addition for the energy absorbed in the transformer, say, slightly over half-a-unit per hour. In arc-lamp circuits it is also very important that the cables and switches should be amply large enough to carry the current, as if they are too small they will get hot and waste considerable power.

The voltage can also be reduced by placing a choking-coil in series with the arc. It consists of a laminated iron core surrounded by a coil of insulated wire, and its action is due to the fact that the magnetism of the core produces an opposing electro-motive-force in the winding with wasting an appreciable amount of energy, as a resistance does. Some choking coils have a straight core, and by sliding this in and out the voltage can be varied. Others are made in either rectangular or ring form, the necessary adjustment being made by connecting to "tappings" or small loops of bare wire left sticking out at intervals, by which means a varying number of turns may be included in the circuit. A small choking coil is sometimes put in series with an arc lamp when the current is taken from a transformer. It has a steadying effect, and

serves the same purpose as a resistance while not absorbing as much power.

It should be borne in mind by those who wish to fit up their own arc lamps that to secure the greatest economy in current consumption it is essential to have a transformer or choker to suit the periodicity of the supply. This is the number of complete alternations or reversals of the current per second, and the different supply bodies vary greatly in this respect. If the periodicity is low there is a perceptible flicker noticeable in the light from an arc. It is said that in certain parts of the North of England the periodicity is as low as 25, and the flickering of incandescent lamps is then quite apparent. A transformer used on a circuit of considerable difference in periodicity to that for which it is designed will get very hot after working for some time, and the generation of this heat naturally represents consumption of power.

Transformers are usually marked with their primary and secondary voltage against the appropriate terminals, and the periodicity, the last being indicated by a wavy line, thus: 50~. When buying secondhand apparatus these figures should be looked for, as it is false economy to save on the initial outlay and incur continual extra running cost. A difference of a few per cent. is, however, generally unimportant.

If the supply voltage is fairly high it is best to instal an auto-transformer or compensator when more than one arc lamp is connected. For instance, on 200 volts from one to four arc lamps can be run in the cheapest manner, as is shown in the diagram, from which it will be seen that in principle the auto-transformer consists of one continuous coil. The winding of the transformer is divided so that each section gives 50 volts, and, assuming the lamps take 10 amperes each, that amount of secondary current will be available for one lamp, the whole four, or any combination. When all the lamps are working the transformer takes practically no current, the lamps then running in series. For the sake of clearness the switches, etc., for each lamp have been omitted.

Direct current lamps give more light than those working on alternating current, especially when designed so that the carbons are vertically in the same straight line. On direct current the top carbon is positive, and the major portion of the light comes from the crater formed at its tip. The light is thus cast down in the required direction, whereas with alternating current both tips emit light equally, and as much is directed upwards as downwards. There is, however, a type of lamp known as the "flame-arc" in which the carbons are inclined like a letter V, the arc being formed at the point. These lamps throw the maximum amount of light downwards, and there is not so great a difference between the results obtained by the two kinds of current. The makers of a well-known pattern give the following approximate figures:—Direct current, 4,500 c.p.; alternating current, 3,400 c.p., with a consumption of 12 amperes in each case.

There are doubtless many photographers who are fond of experimenting with various sources of illumination, but probably few appreciate how easily an efficient arc lamp can be made. If two carbons, from 9 to 11 millimeters diameter, are fixed vertically on a base of some insulating material, and are supplied with 10 amperes at about 50 volts, an arc can be started at their tips by connecting them for an instant with a piece of carbon held in a non-conducting wooden handle. This precaution should not be omitted, as there may be a leakage to earth somewhere on the system, in which case the operator might get an unpleasant shock. The arc will continue to turn steadily, and though the light is thrown upwards, a large reflector can be used to distribute a diffused light on the sitter.

The carbons can also be arranged horizontally, but they must not point downwards to any degree, or the arc will travel up and fuse the connections. It must not be forgotten when experimenting with a simple arc that, unlike a properly-constructed lamp, with its regulating and feeding coils, it must be controlled and kept stable by either a resistance, choker, or transformer. If a transformer is used, a resistance or choker of small impedence must still be employed to control the current taken by the arc. Otherwise there is no limit to the current that will pass, save, of course, the blowing of the supply company's fuse.

To find the amount of resistance wire necessary to pass the required number of amperes, use is made of the simple equation $R=\frac{E}{C}$, where R = resistance in ohms, E = voltage of supply to be absorbed, and C = current in amperes. The fact that the arc itself absorbs about 50 volts must not be lost sight of, as is indicated in the diagram. Assuming that it is desired to run an arc with 10 amperes on a 100-volt circuit, the resistance will therefore have to take up the remaining 50 volts, and the equation will be $R=\frac{50}{10}=5$ ohms. Reference to a price-list of resistance wires will generally show the maximum current that the wire will carry at a certain temperature, and the resistance in ohms for 1,000 yards. It is then easy to calculate the requisite amount of wire of the proper gauge. It is worth while to take some trouble in this matter, as a friend of the writer, leaving things to the discretion of a well-meaning shop assistant, was induced to purchase two or three pounds of thick wire when about 4 ozs. of a much smaller size would have been ample.

The high cost of labour and maintenance at the present time has resulted in the substitution of half-watt for arc lamps in many thoroughfares, with the result that it is often possible to buy the latter at a comparatively low price. These lamps are usually in perfect condition, and the writer has known them to be used to advantage for portraiture. In cases where cost is a consideration it should not be forgotten that the large bulb of a half-watt lamp is easily broken while a well-made arc lamp will stand a lot of knocking about. If purchased direct from a supply company full information will readily be given as regards suitability for the consumer's installation. Should the lamps be obtained through some other channel, care should be taken not to run direct-current lamps on alternating current, or *vice versa*. The writer knew one man who put two direct-current lamps in series on alternating current, the resultant lighting being very poor and the bill disproportionately large. Alternating lamps can be recognised by the holes in both carbon-holders or clips being the same size, while with direct lamps one (the positive) is larger than the other.

Lamps for series running are specially adjusted by the makers, and if it is intended to take advantage of this economical method of wiring it is best to obtain them direct from the supply company, as if bought second-hand from a dealer they may have been separated from others of the series. This precaution is not essential, but its observance will conduce to better working.

Always use the best carbons. Inferior kinds often give an unsteady light, and quite upset the mechanism of an otherwise perfect lamp.

In conclusion, it may not be out of place to say a few words about the danger from shock. The main switch, almost invariably of the "double-pole" type, should always be opened before making any alterations or connections to the wires. A double-pole switch isolates the entire installation, as it breaks contact in both the main wires, but the ordinary single-pole switch controlling one or two lights breaks contact in only one wire. Should there be an "earth" (a fault in the insulation by which current leaks out) on this wire it is still possible to get a bad shock if the other wire is touched, as the current would travel through the body, boots, floor, etc. Some leakage is inevitable, even with the most carefully-laid cables, though it may not be on the consumer's premises.

It must not be forgotten that though the voltage of a shocking-coil may be high, as indicated by the spark, the actual quantity of current is very small. With a public

supply there is practically unlimited current available, and this is what constitutes the danger. There seems no reliable evidence as to how much will prove fatal, though it has been put as low as one-fifth ampere. The quantity that will pass through the body is determined, as was shown in the case of the arc-lamp resistance, by the resistance in ohms of the body, which varies enormously, and by the voltage of the supply.

The writer has personally known of two fatal shocks at 105 volts. One case was that of a bath attendant who apparently encountered an earth when his hands and boots were very wet, thus reducing his resistance to the minimum. In the other case, some boys, for a joke, connected a brass door handle to the lighting service, with the result that the object of their ill-timed pleasantry was killed.

ELECTRICIAN.

THE CARBRO PRINTING PROCESS.

IN a recent pamphlet the Autotype Co. give particulars of recent modifications in the formulæ for this process, due to an amateur worker, Mr. F. Garon, who has extended the method of Mr. H. F. Farmer, of which full particulars were published in the "British Journal" of October 10, 1919. The advantages of Mr. Garon's formulæ are:—(1) The same time of immersion, 3 minutes in bath No. 1 is required by all Autotype pigment papers, with the exception of red chalk, and 2) the quality of the resulting print is very much under control by simply varying the time of immersion in bath No. 2.

The following stock solutions are required:—

A.	Potass bichromate	1 oz.
	Potass ferricyanide	1 oz.
	Potass bromide	1 oz.
	Water	20 ozs.
B.	Acetic acid, glacial	1 oz.
	Hydrochloric acid, pure	1 oz.
	Formaldehyde, 40 per cent. solution	22 ozs.

For use. Normal strength.

Bath No. 1. 6 ozs. stock solution A
18 ozs. water

Bath No. 2. 1 oz. stock solution B
23 ozs. water

The first bath may be used for some considerable time, but the second bath must be frequently renewed, as it is altered by the No. 1 bath transferred to it on each immersion.

First place the bromide print in cold water, then take a piece of pigmented paper cut about half an inch larger than the bromide, and immerse in No. 1 bath for 3 minutes, take out, and holding it by one corner, allow to drip for 15 seconds, then immerse in No. 2 bath for a varying time from 15 to 30 seconds, according to the result desired.

Withdraw from No. 2 bath and squeegee into contact with the bromide print previously placed on a sheet of glass, place between grease proof paper and allow to remain for 15 minutes.

Towards the end of the time of contact of bromide and pigment paper, take a piece of transfer paper cut slightly larger than the pigment paper, and soak in cold water for 2 or 3 minutes.

Complete wetting is necessary.

After wetting the transfer paper, lay it face upwards on the squeegee board. Now take the pigment paper and bromide, and by raising one corner of the former steadily pull the two apart. Place the pigmented paper face downwards on the transfer paper and squeegee the two into contact. Place between blotting paper with a book over them to prevent curling, and allow to remain from 20 minutes to one hour. The bromide print, now bleached, is put into a dish of cold water and washed by frequent changes of water for about twenty minutes.

It is then ready for re-development for further use.

The re-development should be thorough.

The development of a Carbro print is a simple matter, no chemicals being required. The pigment paper on the transfer paper is placed in a dish of warm water. Start with a temperature of about 95 degrees Fah. Keep the two papers, still adhering, well covered by the warm water, and wait until the pigment commences to ooze round the edges. As soon as this occurs, carefully lift one corner of the pigment paper, and, keeping the transfer paper under water, steadily strip the two apart. The transfer paper will now be seen to be covered with a thick coat of pigment.

Gently splash the face of the proof with the warm water, and as the picture begins to reveal itself, the splashing may be local, if it is desired to reduce any particular portion—should the print be too dark—the temperature of the water may be increased.

When development is complete, the picture is rinsed in cold water and placed in a 3 per cent. solution of alum until the bichromate stain has disappeared; it is then finally rinsed.

NOTES AND OBSERVATIONS.

The time of immersion in No. 1 bath of 3 minutes is applicable to all pigmented papers except red chalk, in which case 5 minutes is desirable. Under-immersion is indicated by heavy shadows lacking detail. The time of immersion in the second bath is a point of importance. Complete control over the brightness of the print is ensured by attention to this detail. Depth and brightness are the result of short immersion, an increase of time giving a proportionate increase in softness of the result.

It is not possible to give the exact best time, but 25 seconds when using a bromide of average depth is a good point of departure. Varying grades of bromide paper demand various times of immersion, but with all grades the rule is constant that longer time gives softness, too long a time gives flatness.

Olive Brown with normal bath is inclined to give weak prints. When using this colour it is advisable to make the No. 2 bath of three quarter strength, *i.e.*, 1 oz. of No. 2 stock solution, 31 ozs. of water.

It is desirable to pass the No. 1 bath through muslin after use.

New Books.

First Aid to the Amateur Photographer. By Will R. Rose. Chester: Minshull and Meeson. 2s. 6d.

THIS little manual has been in print for some considerable time, and therefore does not come within the strict definition of these reviews. But, as we ourselves only recently came to know of it, possibly many of our amateur readers are in a like position, and, therefore, we may usefully refer to it. We have the greater desire to do so for the reason that the book differs from the many manuals for the amateur both in its scope and method of treatment. It sets itself out to cater in the most practical way for the requirements of those legions of amateurs whose photography consists of making exposures with a film camera and leaving the rest to somebody else. There is very little about development; nothing about printing or enlarging; but the subject proper—the taking of satisfactory photographs—is dealt with in the clearest possible way, because the teaching is chiefly in the form of snapshot photographs, good and bad. Mr. Rose, in his business, has had extraordinary opportunities of observing the mistakes which are made in the use of a hand camera by the inexperienced; mistakes in lighting, exposing, focussing, and handling the camera; and he has shown extraordinary capacity in making the right and wrong ways plain to those who know next to nothing of photography. There are fewer technical terms in this little book than in any other we know, but nevertheless there is more instruction of the kind which directly serves the end of getting pictures. For the people whose photography begins and ends with the use of the camera, this is the one manual which they should have, for it tells them and shows them just those things which concern them, and in a way which they cannot fail to understand.

MR. E. F. GILBERT has rejoined the travelling force of Houghtons, Ltd., and will represent their professional department in the Southern and Eastern Counties—approximately from Yarmouth to Land's End.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, May 16 to 21 :—

MOUNTING PRINTS.—No. 14,094. Finishing or mounting photographic prints. G. E. Hadley.

DAYLIGHT DEVELOPMENT.— No. 14,092. Daylight photographic developing tank for roll films. E. Jack.

DEVELOPING BOXES.—No. 13,785. Photographic loading and developing boxes. S. S. T. Pratt.

STEREOSCOPY.—No. 13,902. Camera stereoscopic attachment. W. Worsnip.

COLOUR PROCESS.—No. 14,031. Process for producing colonred photographs. E. A. Lage.

NON-PHOTOGRAPHIC NEGATIVES.—No. 14,004. Producing negatives by other than photographic means. F. A, Pereira.

PROJECTION METHOD.—No. 13,862. Means for projecting images of objects on to screens, etc. C. F. Dussaud.

SHUTTERS.—No. 13,990. Device for operation of camera shutters. H. Whitehall.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR PHOTOGRAPHY. No. 160,540 (December 20, 1919).—The invention consists of a toning solution containing potass ferricyanide, uranium nitrate, rose bengal, naphthol yellow, and acetic acid, together with iodine, and in addition to or in place of the iodine an isocyanine dye such as pinacyanol or Sensitol Red.—William Friese-Greene, 41, Portsdown Road, Maida Vale, London, W.9, John Newlands Thomson, 22, Brook Street, London, W.1, and Colour Photography, Limited, of 3, St. James's Street, London, S.W.1. [Formulæ recommended according to the invention will be found on another page of this issue in the "Colour Photography" Supplement.]

DYE-TONING.—No. 147,005 (February 1, 1906). The claim is for the process of converting a silver image into a copper compound and dyeing the latter with an organic basic dye.—Dr. Arthur Traube, 12, Rauch Strasse. Munich. (Further particulars of this specification will be found on another page in the "Colour Photography" Supplement.)

DYE-TONING.—No. 147,103 (December 3, 1918). The invention relates to an improvement in that described in Specification No. 147,005. By the invention the dyes are suitably selected, which is of importance for the success of the picture. While the otherwise very powerfully dyeing triphenylmethane dyes dye sufficiently, they do not correspond completely with requirements. It is necessary that the dye should dye well, not be dissolved away or only to slight extent by washing, and at the same time be possessed of sufficient colour intensity.

By the invention basic dyes of the following classes are used:—Thiobenzenyl dyestuffs for yellow, thiazines for blue, pyronines for red, safranines, oxazines, and acridines.

The members of the several dye classes can be mixed with each other, so that it is not necessary to use a single dye for each dyeing. Dyes of the same or different tints may be mixed.—Dr. Arthur Traube, 12, Rauch Strasse, Munich.

The following complete specifications are open to public inspection before acceptance :—

COLOUR-PHOTOGRAPHY.—No. 163,311 Multi-colour screens for photography J H Christensen.

New Materials.

Scaloid Vedol Developer. Made by Johnson and Sons, 23, Cross Street, Finsbury, London, E.C.2.

A TABLET developing preparation which is certain to find wide favour among photographers, on account of its snitability for every description of work, has just been introduced by Messrs. Johnson under this name It is made up in tablets, the normal working developer being prepared by dissolving one tablet of the developer and one of the accelerator in 4 ozs. of water. The developer works exceedingly cleanly—it seems impossible for it to produce stain under ordinary conditions—and gives density readily, the Watkins factor advised for normal negatives being 12, or 10 if a soft negative is required, or 15 if the aim is one of greater vigour. But what perhaps will appeal most specially to the amateur worker and also to the professional is the use of "Vedol" for time-temperature development by means of the very comprehensive tables published in the circular of instructions. These include a classified table of plates according to their speed of development. The developer is suitable for both bromide and gaslight papers, lantern-slides, and also for the special brown-black papers which have come so widely into use of late. By addition of bromide and extra exposure it likewise lends itself to the making of lantern-slides of a range of tones from brown-black to red. The developer is supplied in cartons containing tablets to make 100 ozs. of solution, price 2s.

SINGLE-SOLUTION INTENSIFIER.—The Henderson-Patton Manufacturing Co., 74, Dame St., Dublin, send us a specimen of a tablet intensifier preparation acting in single solution and very quickly yielding great intensification with reddish-brown colour of deposit. Apparently the intensifier is the familiar uranium formula, or something closely akin to it, for the intensification is completely removed by a weak solution of soda carbonate. It may be doubted if there is now any wide demand for an intensifier of this kind, particularly when issued without indication of its chemical basis. However, the tablets form an effective intensifier, the action of which we prefer to render slower by dissolving in about twice the quantity of water directed by the makers.

BARNET MATT PLATES.—On taking into use the Barnet matt plates, which we mentioned as a new introduction by Messrs. Elliott and Sons last week, we find that we were guilty of an error of description. The matt quality of the plate is obtained not by a coating on the glass side, but in the emulsion film itself, the surface of which allows of any of the retouching work which can be carried out on a matt backing and also of other descriptions, such as fine pencil work, to which a matt backing is not so susceptible. The exceedingly fine grain produced in the film provides for any description of printing, and, moreover, although for a somewhat different reason, is a preventive in very large measure of halation. It is therefore evident that any of those who may have obtained supplies of the plate on the strength of our description will not be disappointed in their use, despite the different manner in which the matt effect is produced.

VANGUARD GROUND GLASS VARNISH.—The Vanguard Manufacturing Co., Maidenhead, send us a specimen of a modified variety of their ground-glass varnish, namely, one yielding an extra fineness of grain and hardness of surface. The preparation certainly yields an exceedingly fine grain, dries very quickly, and yields a surface of such hardness that the ordinary hard retouching pencils can be used on it within two or three minutes after flowing on. The Vanguard Company advise us that owing to its altogether special composition it has the feature of becoming somewhat cloudy at times in warm weather, but that this has no effect whatever upon its practical employment. A further caution in respect to it is that it must on no account be mixed with any other matt varnish. The new product is evidently one which will find many users among those having occasion to carry out retouching work of any description on negatives. It is supplied at the same price as the ordinary matt varnish of the Vanguard Company, namely, 2s. per small bottle, 6s. 6d. per half pint, or 12s. per pint.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, JUNE 5.

Hammersmith Hampshire House Phot. Soc. Outing to Esher.
South London Phot. Soc. Excursion to Cobham and Stoke D'Abernon.

MONDAY, JUNE 6.

Bowes Park and Dist. Phot. Soc. "Home Portraiture." J. R. Smith.
South London Phot. Soc. "The Balance of Light." C. P. Crowther.

TUESDAY, JUNE 7.

Hackney Photographic Society. "Toning and Staining Bromides and Slides." E. C. Ridge.
Portsmouth Camera Club. Final Competition and Awarding of Prizes.
Sheffield Photographic Society. Annual General Meeting.

WEDNESDAY, JUNE 8.

Bradford Photographic Society. Evening Excursion to Hirst Woods.

THURSDAY, JUNE 9.

Hackney Photographic Society. Excursion to Chipperfield.
Hammersmith Hampshire House P.S. "The Negative." O. King
Kinning Park Co-operative Society C.C. "Holiday Hints."

SATURDAY, JUNE 11.

City of London and Cripplegate P.S. Outing to Cowley and Ivor.
Kinning Park Co-op. Society C.C. Outing to Old Kilpatrick.

ROYAL PHOTOGRAPHIC SOCIETY

Meeting held Tuesday, May 31 the president, Dr. G. H. Rodman, in the chair.

The president referred to the collection of radiographs on the walls. This second exhibition of radiography had been brought together with the co-operation of members of the Röntgen Society, and includes many prints of special interest. We must postpone detailed reference until a later issue.

Dr. C. Thurstan Holland then delivered a lantern lecture, "The Snow and Ice Scenery of Switzerland," and, for over an hour, held a large audience greatly interested in a series of photographs, not only representing magnificent technical renderings of very beautiful subjects, but illustrating the natural processes concerned in the formation of the Swiss glaciers.

On the proposition of the chairman, a hearty vote of thanks was accorded to the lecturer.

CROYDON CAMERA CLUB.

Mr. W. F. Slater, F.R.P.S., gave a lantern lecture entitled "Architecture with a Hand-Camera," previously tried and found good at the R.P.S. On an occasion like this, the club in its corporate capacity with peculiar modesty regards itself as a sort of Court of Appeal, which in this case emphatically upheld the prior decision. In fairness, however, it should be stated that the members individually are just as humble-minded as the average amateur photographer, no more and no less, though if modesty had to be expressed numerically, it must be admitted that the sum total derived from certain of the pictorialists would make but a poor show.

It cannot be said that the title of the lecture was particularly arresting, for in these days hand cameras may possess so many movements that architecture is well within their scope. Often in all essentials they are field cameras, but capable of being used in the hand. Equally capable of misuse, and many a plate has found oblivion by being hurriedly exposed with an adjustment out of adjustment. As an instance, one popular member who buys the most expensive cameras every few months finds in each fresh purchase new and glorious opportunities of adding to an unrivalled collection of disasters for which he is so justly famed. The cameras with which Mr. Slater worked were not of this sort, but Kodaks of the simpler type, not even fitted with a rising front, and some of the really splendid slides shown owed their origin to the best-known camera in the world, to wit, the "Brownie." They also well illustrated that the oft-despised R.R. lens is still capable of first-class results, though in most cases a 5-in. Cooke lens working at *f* 6.5 was employed on quarter-plate film. As many interiors require permits to photograph them, Mr. Slater prefers to dispense with a tripod, for, if reposing innocently on a chair or other support the camera is spotted by an attendant, a little friendly discussion permits completion of the exposure. The finder is only used for centring, as practice enables the amount of view included to be judged. Focussing is effected by scale, depth of field being calculated on a confusion disc of 1/250 inch, varying the stop as circumstances dictate. In many cases, he said, it is possible to give prolonged exposures by pressing the back of the camera against a wall or pillar, and frequently a Kodak scores by being able to be used in a position impossible for a camera on a tripod.

A rough guide to exposures for interiors, due to the facile brain-box of Mr. H. W. Bennett, the lecturer had found useful and reliable for Kodak film. In ordinary bright summer light, stop *f* 16, a modern domestic interior with light walls takes 1 minute; with dark walls, 2 to 3 minutes. Naves of churches, badly lit, 1 minute; cathedral aisles, 1 to 4, and choirs, 4 to 20 minutes. Of course, "time and temperature" were well rubbed in at intervals; the last factor was so sweilteringly obvious that dry-ginger and K3 cyder were in great demand.

The discussion was brief and highly appreciative, the president felicitously picturing the lecturer as a "typical London photographer." Occasionally one sees this type about, armed with tripod and attached mysterious contraption, whose main feature is a large pneumatic bulb fitted close, both apparatus and operators usually being sadly the worse for wear. To normal vision the genial Mr. Slater does not resemble them in the least. He was accorded a very hearty vote of thanks.

In last week's report of Mr. Sinclair's lecture, owing to a printer's error or mystic charm of the reporter's handwriting, it was stated that 3 and 6 inch lenses were employed. Lenses of 5 and 6 inch focus were actually referred to.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held Thursday, May 26. Present: Miss Bertram, Messrs. J. Campbell Harper, Swan Watson, George Balmain, E. D. Young and Moffat. Mr. William Hislop, of Messrs. Hislop and Day, Ltd., process engravers, Edinburgh, was also present on the invitation of the Society. Mr. E. D. Young in the chair.

The Chairman explained that Mr. Pirie Macdonald, of New York, who was known to them all as one of the premier photographers in the United States of America, was attending the Rotary Convention to be held in Edinburgh from June 13 to 16 next, and that several members had expressed a desire to do honour to him and to the profession by entertaining him to luncheon one day during the sitting of the Convention. The Chairman explained that he had cabled Mr. Pirie Macdonald on the 19th inst., inviting him, on behalf of the Society, to luncheon, and to name the day, but he had not yet heard from him in reply. The meeting unanimously confirmed the Chairman's actions, and the Committee were appointed to carry through the arrangements. It was resolved to invite ladies to the luncheon, and the Secretary was instructed to send out a circular to all the members inviting their support so that the Society may be fully represented.

Mr. Young reported that he had seen Mr. McNally, the organiser of the continuation classes under the education authority, and had received a very sympathetic hearing from him as to the formation of a class for chemistry and optics as applied to photography. He had framed a letter which he proposed should be sent to Mr. McNally setting forth the particulars of the proposed scheme. The secretary read the letter to the meeting. It was approved of and instructed to be dispatched.

Mr. Hislop, who had for the past sixteen years conducted the class for process engravers in the Heriot-Watt College, gave an outline of the work of the class there. He thought the project of the Society an admirable one, and if the Society were agreeable that process workers should be admitted to the class along with photographers, he was confident that their combined efforts would command success. He offered, should a sufficient number of pupils come forward, to undertake the tuition of the class, which it was resolved to limit to the process workers and photographers. Mr. Hislop was cordially thanked by the members of the Society for attending the meeting, and for the information he afforded the Society. He was also thanked for his kind offer to undertake the carrying on of the class.

An interesting discussion thereafter took place on the comparisons between the minimum prices charged for commercial photography by the process engravers and the professional photographers respectively, and it was agreed to invite Mr. Hislop to the next meeting of the Society, when the prices for commercial photography were to be approved of so that the members might have the benefit of his experience in fixing their charges.

It was resolved to give a donation of one guinea towards the prize fund for the retouching class at the College of Art, and the Secretary was instructed to remit the same.

A vote of thanks to the Chairman concluded the meeting.

Commercial & Legal Intelligence.

NEW COMPANIES.

Daniel Chinery, Ltd.—This private company was registered on May 25 with a capital of £1,000 in £1 shares. Objects: To carry on the business of photographers, photographic artists and printers, manufacturers of and dealers in photographic apparatus and chemicals, cinematograph film producers, etc. The subscribers (each with one share) are: C. W. D. Chinery, 3, Silverton Road, W.6, automobile engineer, and Mrs. F. M. Chinery, 3, Silverton Road, W.6. C. W. D. Chinery signs as "director." Qualification, 50 shares. Remuneration as fixed by the company. Registered office: 13, Eccleston Street, S.W.

News and Notes.

Focussing Magnifiers.—Messrs. A. W. Penrose write from their Glasgow offices, 347-349, Cathedral Street, pointing out, in reference to our article of last week, that they have just placed on the market a low-power fixed-focus magnifier with a sucker end, which readily adheres to the ground glass screen. A magnifier of this kind is particularly useful to the general worker, outdoors or in the studio. It is supplied by Messrs. Penrose, price 6s. 6d., post free.

Death of Mr. L. F. Hammer.—The death is announced of Mr. Ludwig F. Hammer, for many years a prominent manufacturer of dry plates in the United States and head of the Hammer Dry Plate Company. Mr. Hammer, who was a native of Germany, made his home in America in the first half of the last century, and after many years of success as a professional photographer founded the business which still bears his name. Throughout American photographic circles he was very greatly esteemed for his cordial and amiable nature, and his death, at the age of 87, removes a personality that will be keenly missed.

The Club Photographer.—Having cast its two previous titles our young and lively Liverpool contemporary has now appeared under the above title, chosen in reference to its representation of the interests of photographic societies throughout the country. It signifies this broad policy by devoting its literary and illustration pages solely to contributions by the Hammersmith (Hampshire House) Photographic Society. The members of this body contribute the articles and originals of the art supplement, notable among the former being a useful series of notes on the handling of panchromatic plates. Our contemporary is clearly showing its capacity to make a place for itself in photographic journalism, and should certainly make many readers both inside and ontside the ranks of photographic soc.eties. It is published from the headquarters of the Liverpool Amateur Photographic Association, 9, Eberle Street, Liverpool, price 3d. monthly.

Picture-Hanging Wire.—Mr. A. G. Stubbs writes to "Nature":—I have for many years past used and advocated the use of plain copper wire in preference to any other means of suspension. The only matter that calls for carefnl attention is avoidance of "kinks." With heavy pictures my practice is to have two entirely independent suspensions—screw eyes, wire, and wall nail or hook—the duplicate being entirely screened by the picture, and either actually or so nearly sharing the weight that should the other suspension fail it could take the whole load at once without jar.

If I use a (nailed-on) wall-hook I put a stout nail immediately beneath to provide against failure of the brass hook, and I have found it a good plan when using a brass-headed nail to drive in a wire nail at a steep angle beneath it so that the head of the wire nail lodges beneath the brass head. The wire nail acts excellently as a strut.

Handelchrome Portraits.—We have recently had an opportunity of seeing a number of examples of a new departure in oil portraits in colours which owes its origination to Mr. E. G. Handel-Lucas, doubtless well known to many of our readers both as a painter of repute and as a technician in photographic methods, particularly in relation to colour photography. For several years past Mr. Handel-Lucas has been engaged in perfecting what we understand to be a new technique in the making of oil portraits in colours. We do not know anything of the technical methods which are adopted, except that a photographic print is employed as the basis. But we are able to extend a very cordial appreciation of the results. The Handelchrome portraits are characterised by very remarkable freshness of colour and drawing. In the latter respect they immediately impress one as being striking likenesses of the subject. That may be due in part to the employment of a photograph as a basis, but we believe that Mr. Handel-Lucas makes it his practice to study the original sitter whenever that is possible. At any rate, it may be justly claimed for the Handelchrome portraits that they strike a new note in colour portraits, and will recommend themselves both to photographers and their customers by the very great technical perfection and their altogether distinctive character. They have been compared with the effect which one sees when looking at oneself in a mirror; and the comparison is an apt one in giving an idea of their realistic quality. We learn that Mr. Handel-Lucas is busily engaged in fulfilling commissions, which have resulted from a comparatively limited announcement of his work, and that further particnlars of the process may be obtained by application to him by letter at 169, Gleneagle Road, Streatham, London, S.W.

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Clnb. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Malt East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.I.

MADAME YEVONDE'S LECTURE.

To the Editors.

Gentlemen,—I had not the pleasure of listening to Madame Yevonde's lecture, so am free from the hypnotism of the lady's wit, or is it "tact," so often alluded to.

Anyway, the whole tenor is very misleading and unfair to all, although I fancy her own sex will be most misled, as the lady so strongly maintains photography is essentially a woman's business, and so fits the feminine qualities of "tact," etc. This kind of talk is but too likely to create a crowd of deluded people, seeking an easy living by their tactful acquiescence and flattering smiles to the new baby, the girl with her latest blouse, and the bride-groom; but do not these form but a very small part of a photographer's work? How does Madame Yevonde suppose her tactful ideas are to work with sitters who have stronger characters, when it is a case of coming up to the sitter's level, not down. How is it to be used in photographing machinery, architecture, furniture, jewellery, etc., or from a lofty building's scaffolding, or a ship's crankshaft, or 3,000 ft. up in an aeroplane? These and more intricate, technical and difficult work I have been called upon to do; all photographers are at times. Photography as a living requires long and arduous application early and late of technical expertness, as in the old wet-plate days, with real art discrimination, quick judgment, ready adaptability, and sound business acumen, and then you are getting somewhere near it. A camera, a packet of plates (with instruction by post), some blue and pink bows in the window, and tact, spell dismal failure. Again, how is it that women are so disliked as employers? I have yet to find the employee who prefers a woman to a man. Why doesn't the "tact" work with the servants at home?

As for the man who left the work to his girl assistants, well is that a criterion of their ability or his mental inferiority? And as for the dear, old gentleman of 35 years' experience, who advertised "perfect" pictures, I am afraid we are now suffering from the imperfect advertising; it won't work now—the public knows.

In 1914 I left for the war, returning in 1919, I applied for a manager's job, the two girl managers leaving to open a place of their own. "Don't take this place; come with us as assistant," they said, but neither knew anything but plate and paper makers' instructions, and had picked that up whilst I was away on Service. I believe they ran for twelve months, like many another war-time product, and, finally, lost all. To any deluded by Madame Yevonde's "tact" to start in photography, I copy "Punch" and say "don't."—Yours faithfully,

1914

THE STUDIO WORKER AND THE SHOPS ACT.

To the Editors.

Gentlemen,—The official view recently quoted ("B.J." May 13, p. 273), that "the actual taking of a photograph is a part of the *process of manufacture*" (the italics are mine) sounds suspiciously like the Factory Act, and if any question of applying the Factory Act to studios arises both employers and employees will be affected in many cases.

Now it is only just and reasonable that a photographer should be free to make appointments without being shackled by the apron strings of bureaucracy, but if assistants are employed for appointments out of regular business hours, and "process of manufacture" is pleaded against the Shops Act, we ought to be prepared to observe the laws regulating processes of manufacture.

At least six of the clauses of the Factory Act would have significance for studios were the Act to apply. Under these clauses it would become compulsory to provide adequate ventilation, heating arrangements, and sanitary accommodation for all employed. Provision would also have to be made for escape in the event of fire. The maximum hours of employment would have to be definitely fixed for the first five days and for Saturdays, and no woman could be employed on Sundays, Christmas, Good Friday, and the four Bank Holidays would be compulsory holidays for all employees in England and Wales, and other days in Scotland and Ireland.

Admittedly many of the studios which make a specialty of sittings by appointment are already well within the above provisions, and the Act could be applied to them without their knowing it or being inconvenienced in the least, but there are others which are not up the Factory Act standard and yet might wish to enjoy freedom from the Shops Act. This is the crux for employees. Before the Shops Act was law, studios were open all hours on all days, and there were no rules or regulations governing working hours. This Act gave a certain half holiday to many who had not had it before, and also shortened their daily hours, but if it is no longer of any significance to those employed in the studio and presumably in other work-rooms, they must either come under the Factory Act or drift back to pre-war conditions. There is, however, no reason at all why the interests of both employers and employees should not be safeguarded. Appointments could be freed from red tape without assistants being rendered liable for it. Under the Factory Act it should be possible to arrange for work out of usual business hours on an overtime basis subject to mutual agreement. This would mean that special appointments at which the services of paid employees were required would benefit not only the customer or the customer and the owner, but the employees as well. As things are at the moment the latter seem to be rather out of the running as regards the case in point.

THERMIT

PICTURE WIRE.

To the Editors.

Gentlemen,—Perhaps a few remarks apropos this subject, and in reply to Mr. R. B. Marston's complaint, may find an odd corner in your valuable space.

In choosing a wire there are three main points to consider, viz., strength, appearance, and durability. The saying, "Unity is strength," is exemplified in this article when new. I say advisedly "when new," as deterioration sets in when exposed to dampness and the various chemical actions in the air, the fineness of the strands, of course, laying themselves more open to attack.

True, there have been some brands placed on the market, such as autobronze and gilt copper, that have answered all requirements admirably, but the price precludes them from general use. When hanging pictures, I always advise customers to hold an annual inspection.

To sum up, for general purposes, such as for studio curtains, workroom fittings, etc., where appearance is *not* of primary importance, the single strand copper wire is preferable on all counts including economy.

FRAMER.

THE WOMAN IN PHOTOGRAPHY.

To the Editors.

Gentlemen,—It is very interesting to know that "Onlooker" regards the lady photographer as a passing fad. Lady photographers have just as good a reason for taking up the work as men, to help earn the daily bread. Before I had a business of my own I started in a country place against tremendous odds. I was a lady assistant to three men, who never gave me a chance to do anything but just the work I was paid for, though I was eager to learn.

Women are good at details; that is why they do well in photography when they have the chance. Besides doing business, I have a large house to look after, with the help of one little maid, and my husband says I am a good cook. I expect "Onlooker" does not know much about women. He will be an onlooker at a football match on a Saturday afternoon.

I cannot write more. I am off to take a group of footballers with a cup they have won from a good many teams.

THE WOMAN IN PHOTOGRAPHY.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B. H.—D.50 is made and sold by the Cooper Research Laboratory, Watford, Herts.

G. E. A.—For particulars of the Carbro process apply to the Autotype Co., 74, New Oxford Street, London, W.C.1.

C. T.—Possibly the brush is out of order, but fine grain can only be obtained by high air pressure. Don't have paint too thick. Pumice on print will have no effect. We don't think it is the fault of the colour as we have often used the same.

A. N.—As regards glazing in quantity, perhaps we should refer you to an article by Mr. Brangwin Barnes, in our issue of April 1, 1921, page 185, which gives very full details of glazing by means of ox-gall., which is the process very largely used.

W. P.—For machinery for coating with the ferro-prussiate or ferrogallic sensitisers the two best firms are Messrs. R. W. Munro, Ltd., 103-149, Cornwall Road, South Tottenham, London, N.15, and Messrs. N. L. Scott and Co., Ltd., 3, Pancras Lane, Cheapside, London, E.C.4.

E. G.—Messrs. Billcliff, Richmond Street, Boundary Lane, Manchester; the Magna Co., 2, Eastborough, Scarborough; the Quta Co., 252-254, Haydon's Road, Wimbledon, London, S.W.19; and the Victoria Frame Co., 103, Anglesey Street, Lozells, Birmingham, are the firms supplying ferrotype and similar cameras.

S. D.—Certainly you can have a $3\frac{1}{2} \times 2\frac{1}{2}$ inch adapter, and the only difference will be that a narrower angle of picture will be taken, that is to say, from a given standpoint you will get exactly the same picture as on a quarter-plate except that a margin of $\frac{3}{8}$ inch width will be missing. The camera will not need to be re-scaled.

M. H.—It is very difficult to get a background black enough to show up a dark figure effectively. In the present case the negative is rather under-exposed. If, as we suppose, the coat is red, a panchromatic plate and a fairly deep filter, say, K.3 or Ilford Gamma, should have been used. Italian cloth has too much gloss to give a good black. Serge or velvet is better, and these should be kept well back in the shadow. We should not call the print inartistic though, as you realise, it is rather "spotty."

W. J. B.—(1) Assuming that the ammonia is of the full strength of .880 or .885—much that is sold is not of this full strength—the specific gravity for half-strength is about .938. We are afraid we cannot tell you what the corresponding graduation should be on the 0-40 scale to which you refer. (2) The M.Q. formula is certainly rather weak for ordinary work. The same chemicals dissolved in 40 ozs. of water would be somewhere about normal, but, on the other hand, the formula was recommended for process plates, which readily give density.

H. J.—A trough made of a bent piece of tin is a very suitable holder for the flash powder. The latter is very conveniently fired by putting a small piece of gun-cotton (from the druggist's) at about the middle of the train of powder and lighting this by means of a match on a rod. With an $8\frac{1}{2}$-inch lens on a whole-plate you would probably require to use stop from $f/16$ to $f/22$, and depending on the colour of the walls of the room from, say, $\frac{1}{4}$ to $\frac{1}{2}$ oz. of powder. A lens of this focus on a whole-plate is a comparatively narrow angle for an interior subject of moderate size. If you are required to get in as much of the room as possible you will probably find it necessary to use a lens of not more than 6 inches focal length.

H. S.—We think the best means for avoiding the deep tone of the elder boy's face would be to make a P.O.P. print from the negative in well diffused light with an opaque paper patch on the part to be treated. Then, when the main part of the subject has been printed to sufficient depth this patch should be removed and replaced by a mask covering all of the negative except the part which was previously covered. You could now print the elder boy's face to the required depth and make a copy negative from the toned and finished P.O.P. In carrying out this process it will be necessary to bind up the negative with two or three sheets of glass of the same size, so as to provide some distance, from $\frac{1}{4}$ to $\frac{1}{2}$ inch, between the negative film and the masks.

Dr. J. M. D.—The only formula we know for a persulphate solution of reasonable keeping properties is that of Mr. H. W. Bennett, as follows:—

Ammonium persulphate	480 grs
Sodium sulphite	96 ,,
Sulphuric acid	48 minims.
Water	10 ozs.

Subsequently Mr. Bennett advised 85 minims of sulphuric acid in preference to the quantity given in the formula. For use, 1 part of solution is mixed with 9 parts of water, forming a 1 per cent. solution of persulphate. We have not had any experience of this formula ourselves, but Mr. Bennett is a very reliable technical worker, and we have no doubt the formula does what he claims for it, although we are bound to think that the sulphite is immediately oxidised by the persulphate.

W. A.—(1) The usual pigment for holding back parts of the negative by applying the pigment to the glass side, is carmine, the ordinary tube water-colour. You require to mix it with a little gum solution in order to make it adhere to the negative. (2) Methylated spirit will not do any harm to plates during the short time they are exposed to its vapours whilst backing is drying. (3) It requires a good deal of practice to turn out a number of gold-toned P.O.P. prints of identical tone, particularly if you use separate toning and fixing baths. Perhaps you would succeed best by toning prints as far as they will go in a batch of toning bath measured out for a given number of prints. The instructions for Solio P.O.P. (Kodak) give the necessary directions; or you could use the combined toning and fixing bath, which does not yield so easily the very finest results in P.O.P., but in the hands of a beginner gives a much better average of results, especially as regards uniformity, than the separate toning method. (4) Double toning in P.O.P. means a bluish tone in the high-lights or light parts of the prints, whilst the shadows are still not completely toned, and, therefore, have a warmish colour.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3188. Vol. LXVIII. FRIDAY, JUNE 10, 1921. Price Fourpence.

Contents.

SUMMARY

In the present issue we begin the publication of a series of chapters written for the purpose of presenting the elements of the scientific principles concerned in the making of negatives and, in a measure, prints, which are correct reproductions of the original subject. These chapters are, in fact an exposition of the work of Horter and Driffield, and endeavour to set forth their doctrine in the simplest possible way. The first chapter deals chiefly with the terms "density" and "opacity" and the description of a theoretically perfect negative in terms of the former. (P. 335.)

The several working formulæ reducer, stain remover, sepia bleach, re-bleacher, re-developer and hypo-eliminator—which may be compounded with permanganate as their staple constituent, are the subject of an article by Mr H C Inskeep. (P. 339)

There is a systematic way of securing the greatest degree of depth when using a large-aperture lens. A note on this item of practice will be found on page 333

The method to be adopted in providing view negatives with neatly lettered titles, either in black on the white margin of the view or in white in one corner of the foreground of the subject, is described in an article on page 334, containing the necessary working directions.

Now that the slower development papers of long range of gradation are so much more widely used, a useful purpose is served in emphasising their distinctive qualities in comparison with gaslight papers, and particularly as regards the type of negative most suitable for them. (P. 334)

Mr. Marcus Adams, lecturing on "The Eyes in Portraiture" before the Pictorial Group of the Royal Photographic Society said that the photographer excelled the painter in the delineation of the eyes, and that the creases around the eyes were of immense value in portraiture (P. 345)

Since the eye cannot appreciate even great differences in the strength of illumination, a common error in the use of artificial light in the studio is failure to make allowance for the lesser strength of lighting caused by greater distance of the source of light. (P. 334.)

Details of construction of a lens for which special qualities of "plasticity" are claimed will be found in a recent patent specification. (P. 344.)

The care which requires to be given to the use of the very convenient single metal plate-holders is probably the sole cause of dissatisfaction with these accessories in the hands of the less experienced. (P. 334)

A very interesting collection of X-ray pictures is now on view at the Royal Photographic Society. Among the most interesting of the exhibits is a series of radiographs of the hands of some famous people. (P. 342.)

EX CATHEDRA.

Focussing with large Apertures.

Purchasers of very rapid lenses with apertures of *f* 3 or *f* 3.5 and of considerable focal length, say 12 inches or over, are often disappointed with the depth of focus in the resulting pictures. Such lenses are, of course, mainly used for portrait work, and although their covering power is much greater than the old portrait lens of similar aperture they do not possess any more depth. To make the best use of them, focussing must be done very carefully and the focus "divided," so as to distribute the definition as far as possible. If a large head is to be taken, the eye should first be got as sharp as possible. Then, keeping a focussing magnifier upon it, the camera back should be racked in until it is only as sharp as is necessary to give good definition upon the paper to be used for printing, many of the surfaces now in use being incapable of rendering critical definition. Most of the modern rapid lenses are fitted with a diffusing adjustment, and if this be set for a very slight softening, not enough for a "soft focus" effect, it will apparently increase the depth of focus (or field), this being due to the fact that there is no critically sharp point in the portrait to start from. For children's portraits with such lenses it is advisable to keep the image as small as possible, even if it is necessary to enlarge subsequently, when large heads are required.

* * *

Organised Photographers

During the present month one of the foremost professional photographers in America, Mr Pirie Macdonald, of New York, hopes to pay a short visit to this country, and will, it is hoped, have the opportunity of conferring with his professional brethren. Should he come to London, the Professional Photographers' Association will not let slip the opportunity of hearing the views of one who has been fighting the battles of photographers as a body in the United States for many years past. Mr. Pirie Macdonald represents in his own person a great deal more than a skilful and very successful "photographer of men." Ever since he arrived at success in New York he has thrown in his lot with the various movements for the organisation of photographers as a whole, and has done yeoman service, particularly in connection with copyright legislation in America. Mr. Macdonald, as we had occasion to say some weeks ago when reprinting a speech of his, is a combination of idealist and shrewd business man, and has a way with him which evokes enthusiasm, even from those reluctant to admit the effectiveness or necessity of corporate action among men engaged in the same business. But he has preached full representation of that business as an essential to the vitality of an organised body. To quote a dictum of his:—"A postmaster-general will listen to a society of a thousand

members, but a society of ten thousand members is able to induce him to listen to reason." Latterly, Mr. Macdonald has devoted himself to promulgating the value of a code of ethics to which professional photographers might well pledge themselves; and if he is heard in London it is very likely that he will give his audience the opportunity of a fruitful discussion around that theme.

* * *

Slower Papers. A great improvement in the quality of photographic printing is likely to result from the growing use of slower printing papers. Most of our leading manufacturers are now offering papers which require many times the exposure which is necessary for the bromide emulsions which have so long held the field, and it will be found upon trial that a much longer scale of tones can be obtained upon the new papers than was possible with the old ones. These papers must not be confused with what have been known as "gaslight" grades, for while the latter were almost invariably suited for thin or flat negatives, the newer papers give the best results with such negatives as would give a good print on P.O.P. or carbon. It is, of course, possible to obtain fairly good results from such negatives upon ordinary bromide paper, but as a rule the prints are lacking in quality and of poor colour, this being due to the fact that a full exposure and short development have had to be adopted in order to avoid vigour. With the new papers it is necessary to use a rather intense light, mercury-vapour or half-watt lamps being the most convenient. As the latter can now be obtained in small sizes and with the ordinary fitting, it is easy to substitute them for the ordinary lamps in any printing box.

* * *

Light-Distance and Exposure. A point which is commonly overlooked in taking portraits by artificial light is the effect upon the time of exposure of altering the distance between the light and the sitter. The photographer who has only been accustomed to daylight work does not realise that by moving the sitter three or four feet to secure a certain effect of light he may be doubling or halving his working light. The ordinary rule that the intensity of light is in inverse ratio to the square of the distance between the source of light and the object it falls upon is strictly correct only in the case of an illuminant of very small area, but it will not be far wrong if applied to ordinary portrait work. To give a simple example, we will suppose that at a distance of six feet from the light an exposure of two seconds is sufficient; at eight feet six inches four seconds will be necessary to give an equally exposed negative. This principle has also an important bearing upon the exposure of full-length figures, in which the difference of distance from the light between the head and the feet may be four or five feet in such a case. The head at four feet from the light will receive four times as much light as the boots which are, say, eight feet away.

* * *

Single Metal Slides. The single metal slide has become increasingly popular of late years among hand-camera users, and in some respects it has advantages to offer over more elaborate patterns, as regards the cost, weight, and freedom from the tendency to warp from damp. One point, however, is essential in its use if fogged plates are to be avoided; the re-insertion of the shutter into the slide, after the plate has been exposed, should always be done quite squarely, and not from one corner, as this tends to depress the light-trap, allowing the admission of stray light. The other day we were asked to help in diagnosing the cause of some plates which were very badly fogged along one edge; the trouble was eventually traced to this careless insertion of the shutter. Care should also be taken to see that the draw-out shutter slides straight into its groove in the slide. We have seen photographers who insert the shutter with a wobbling back and forward motion that tends to allow the admission of light. Lastly, the worker should take care that the shutter is inserted in its groove, and not between the slide and the camera back. Some of the apparatus upon the market that is not too well made allows plenty of room for a wrong insertion of the slide in this way. In fact, we know of a really careful worker who made this mistake, and only discovered the error when upon the withdrawal of the dark slide the shutter fell to the ground, leaving the plate uncovered.

TITLES IN VIEW NEGATIVES.

WHILE it is often said, with much truth in most cases, that the photographer in a given place is best qualified to produce the series of view postcards of the locality, that statement must, we think, be qualified as referring to the selection of the views and their production purely from the photographic standpoint. When it comes to the minor details of neatly incorporating titles or other lettering with the postcard views, the local photographer in our experience is almost always woefully neglectful of what should be done, and is done, by the large producers of postcards. We have often been astonished at the untidy lettering of postcard views, on many of which the title and the photographer's name are an unsightly disfigurement of really good photography. This deficiency must surely be recognised by the producers of such cards; its existence is presumably due to ignorance of the methods by which titles can be very neatly added to the postcards by photographic means. A few notes on a subject which is often the subject of inquiry from correspondents may therefore be of service to others.

For economy in this operation it is as well to make a whole series of titles at one time. The neatest lettering is undoubtedly obtained by getting the titles set up in a fairly bold, but not "condensed," type, by a printer, but if this cannot be done it is within the capacity of most studios to draw the titles by hand, using as a model either a given fount of type or one or other of the styles of script lettering, such as can be found in the educational copy books of Vere Foster. If this is done the lettering should be made on a very much larger scale (say five or six times) than is required in the negatives. Any irregularities in the drawing will almost disappear in the reduced version. In copying from large type, such as that available in the specimens of a type-founder's catalogue, individual letters may be traced in pencil on engineer's tracing cloth, and the outlines thus obtained filled in with Indian ink by means of a fine sable pencil.

A sufficient number of titles having been obtained, they are arranged together on an easel so that in the copy negative, now to be made, a space of at least a quarter of an inch is left between each. The negative is best made on a "process" or photo-mechanical plate on which ample density of the ground can be obtained with practically glass-clear outlines of the letters. Although "process" plates are slow, their latitude in exposure is small, and the best results are obtained only by hitting just the right exposure. With pyro-soda or hydroquinone developer, preferably made up according to the formula recommended for the "process" plate, there is, however, no difficulty in getting an excellent black-and-white negative. After development, fixing,

washing and drying, the film is cut through to the glass, using a steel straight-edge and a sharp pen-knife. The titles are thus cut into separate sections of the emulsion film. Each separate piece has now to be transferred to its respective negative. This is done by soaking the negative in a hydrofluoric acid stripping mixture, such as that recommended in the formula in the "Almanac" (page 449 of the current issue), and consisting of 25 ozs. methylated spirit, 1 oz. water, 1 oz. glycerine, to each ounce of which mixture from 10 to 20 drops of commercial hydrofluoric acid are added to form the stripping mixture. It is hardly necessary to say that care should be taken in handling, or rather refraining from handling, the hydrofluoric acid. The latter should be purchased in a gutta-percha bottle, the stripping mixture made in a vulcanite dish, and a plate lifter used in handling the negative, so that the fingers require to touch only the edges. After treatment in the mixture, each narrow band containing one title can be readily raised, detached and transfered to the view negative. Before applying the title strip to the latter it is usual to cut out a strip of the emulsion film with a sharp pen-knife, so as to provide a clear space for the reception of the strip bearing the title. By providing a little adhesive in the shape of weak gum solution applied to this bared strip and allowed to dry, the band of film will readily adhere when the negative is dry.

As a rule, and for the best effect in the printed postcard, this title is put on the negative, where it will print close to the bottom edge of the postcard, and the subject of the latter is then masked so as to give a narrow white margin all round the view on the printed card. This masking is very readily done by first drawing lines in Indian ink with a drawing pen, T-square and set square. The further blocking out, on the outside of the rectangle made with the drawing pen, can then be speedily done with a good blocking-out mixture, such as Vanguard "Photopake." In using this on the marginal part of the negative containing the transferred title, the fine brush is taken up as close as convenient to the letters; ample density of the title negative is, of course, necessary to prevent any tint showing around the letters in contrast with the white of other parts of the margins which have been fully blocked-out.

Some postcard makers, on the other hand, prefer to make a feature of cards in which the view extends right to the edges of the postcard. In this case the title has to be put on to some part of the foreground of the subject where it will show up on the print. For this purpose a positive of the lettering, that is to say, in black on a transparent ground, is usually better than the negative, since the white letters which are thus impressed on the postcard will show distinctly on any subject, whereas black letters are liable to be inconspicuous if the subject happens to have a particularly dark foreground. In this case it is a simple matter to print a positive by contact on to a second "process" plate, and to cut up and strip the titles as already described for a negative direct.

THE H. AND D. DOCTRINE.

In the series of chapters, the first of which appears below, an endeavour is made to present the elements of the scientific principles which are concerned in the processes of making photographic negatives and prints. The discovery of these principles was chiefly due to Hurter and Driffield. While researches on somewhat similar lines were made by previous investigators, the methods and conceptions originated by Hurter and Driffield have proved so fruitful that the title adopted above for this very elementary introduction to what is now the science of sensitometry is fairly justifiable. That science has been enlarged in many directions during the last twenty years, and now represents a considerable volume of literature, chiefly scattered in periodical publications, but accessible through the bibliography appended to the collected researches of Hurter and Driffield in the memorial volume published under the editorship of Mr. W. B. Ferguson, K.C., by the Royal Photographic Society at the price of twenty-five shillings.

Since the output of original papers written in the language originated by Hurter and Driffield and by later experimenters is growing year by year, it seems desirable to put the fundamentals of sensitometry in a form in which they can be understood by the non-mathematical reader. The following chapters are a first step in that direction. Although they do not take the student very far, they will, it is hoped, enable him to become familiar with the methods and terms which are the basis of a great deal of present-day research in photography. They should do much towards enabling him to extract the meaning from papers which he may regard as incomprehensible.

The first chapter deals with the optical conditions which a negative fulfils if it is a theoretically perfect record (in negative form) of any subject. It also explains the meanings attached in sensitometry to the terms exposure, opacity, and density, and will it is hoped, make plain the difference between the two latter.

I.—THE THEORETICALLY PERFECT NEGATIVE.

In making a negative the obvious aim is to record correctly the relative brightnesses of the parts of the subject—that is to say, the amounts of light which they reflect; in other words, to reproduce in inverse light and shade the tone-values in the subject, or, what amounts to practically the same thing, the tone-values in the lens-image of the subject. In a photographic negative this inverse rendering consists of deposits of granular silver formed in the gelatine by the developer, and it is self-evident that a negative is theoretically perfect when the light-intensities transmitted through these various deposits are respectively in inverse proportion to those emitted by the corresponding parts of the original subject. Thus the negative of, say, a drawing (Fig. 1) consisting of five tones of respective brightnesses expressed numerically as 20, 12, 8, 4 and 1, would consist of five silver deposits transmitting respectively

1 20th, 1 12th, 1 8th, 1 4th and 1 1 (the whole).....(A)

of the light falling on it, as shown in Fig. 2; or

1 10th, 1 21th, 1 16th, 1 8th and 1 2 .....(B)

or any other series of deposits exhibiting this proportionality of transmission of light by the respective parts. (Fig. 2.) Obviously only a negative answering to this description is a theoretically perfect substitute, in "negative" or inverse form, for the lens-image of the original subject, for the purpose, for example, of preparing a true positive version of the original by printing on to a light-sensitive paper, also theoretically perfect. It is also clear that negative A is better than negative B in one respect—owing to the larger proportions of light which it transmits it prints more quickly than any other.

The truth of the above definition had been admitted by students of the photographic process long before Hurter and Driffield formally expressed it in the above terms, but it was

not until Hurter and Driffield published their "Photo-chemical investigations" in 1890 that the conditions under which such a theoretically perfect negative is produced were defined and the laws established expressing the relation of light-intensities transmitted by the silver deposits in a perfect negative to

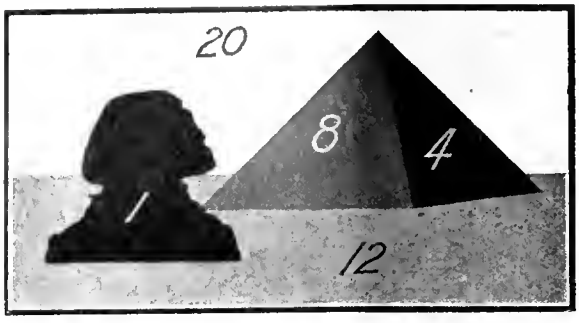

FIG. 1.—A LANDSCAPE OF ABRUPT BRIGHTNESSES.
In five tones, emitting light-intensities in the proportion of 20 : 12 : 8 : 4 : 1.

the exposures (amounts of light) which produce them and the process of development. It will be seen that exposure and development take each an essential but different share in producing the theoretically perfect negative as defined above.

Sensitometry and its Language.

These laws were worked out mathematically by Hurter, and the practical conditions in which they apply and the effects of departure from those conditions were ascertained by the experiments made by him and Driffield. While the two investigators began their work for the purpose of finding a scientific measure of the sensitiveness or speed of plates, their researches had a much wider result, and established a system of expressing the qualities of plates and negatives in definite figures or curves, and of providing a numerical or graphic language for the exact description of both the action of light on plates and the action of developers. In other words, they were, in fact, the creators of what we now call "sensitometry" (the science of measuring the properties and behaviour of light-sensitive substances), and though other sensitometric systems have been devised, theirs still remains the most useful.

The language which Hurter and Driffield introduced is now in every-day use by experimenters in sensitometry, yet is still Greek to large numbers of photographers, who are thereby denied the opportunity of studying a large and important mass of literature and of carrying out and describing any experiments they may make in the most definite way. This does not arise from the fact that Hurter and Driffield employed mathematical methods much beyond the powers of most people.

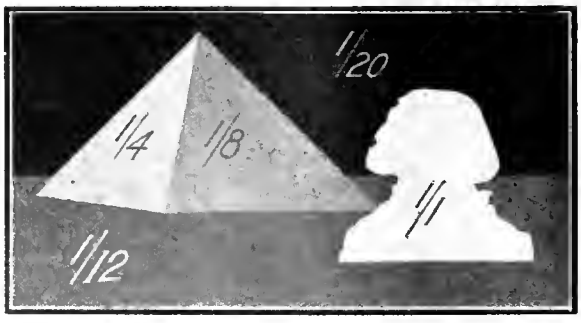

FIG. 2.—THEORETICALLY PERFECT NEGATIVE OF FIG. 1.
The numbers represent the relative light-intensities transmitted by the various parts.

These methods are used by them chiefly in arriving at simple formulæ. The obstacles in the way of assimilating their work from their own writings or those of others are of a much less serious kind. They are, in the first place, the understanding and use of logarithms, which anyone can master for this purpose in an hour or two. Secondly, the use of the word "density" in an altogether special sense, different from photographers' use of it; and, thirdly, that Hurter and Driffield never directly measured densities (in their sense of the word), although they and many other later authorities on sensitometry constantly write as if they do. They measure opacities, or, rather, transmissions, and express them as densities. The confusion introduced in these two latter ways into the study of sensitometry by laymen is perhaps more largely responsible than anything else for the difficulties which are experienced. Particular attention is therefore invited to them in what follows.

Fundamental Values.

It is the basis of sensitometry that we shall express the factors concerned in the making of negatives by numbers (values), not simply describe them by terms, such as large or small, high or low. Some of these numbers are ratios (proportions); others are definite quantities. We must therefore consider these fundamental factors and the manner of expressing them by numbers.

The amount of light which acts upon a plate—that is, the exposure which the plate receives—is measured by the intensity of the light, usually denoted by I, multiplied by the time, t, during which it acts. The intensity is conveniently measured in terms of the light of a standard candle at the distance of 1 metre; the time is measured in seconds. Thus an exposure (I t) of 40 seconds to the light of a standard candle at 1 metre distance is 40 candle-metre-seconds. Other (stronger) sources of light are often used, and are usually rated in terms of the standard candle.

Under certain conditions of experiment exposures represented by identical products of I and t produce equal results, however I and t may vary. This is the so-called Bunsen-Roscoe or "reciprocity" law, but it does not hold good in all cases.

Transparency and Opacity.

The proportion of light transmitted by a patch of silver deposit in a negative, *i.e.*, the *transparency* of that deposit, is expressed as the fractional part of the unit light falling on the other side. Thus, if 1/10th of the light is transmitted we call the transparency 1/10.

But instead of speaking of a substance as having such-and-such transparency, we can speak of it as having such-and-such opacity, transparency and opacity being inverse terms for the same property according as one considers the fraction of unit light-intensity which is transmitted or the multiple of unit light-intensity required for a transparency of 1. The two terms are names for the same thing expressed in different ways. Thus opacity is expressed as the inverse or reciprocal of the fraction denoting transparency, *e.g.*, a transparency of ½ is an opacity of 2. Beginners in the study of sensitometry appear to find a difficulty in becoming familiar with this relation of opacity to transparency. A common pitfall is to think that a completely transparent substance (transparency therefore = 1) should have opacity = 0 instead of = 1. This misconception perhaps arises from the wrong idea that a substance subtracts from the light-intensity which falls on it. It is overlooked that the numbers representing transparency and opacity are ratios. Transparency is the ratio,

$$\frac{\text{light-intensity transmitted}}{\text{original light-intensity}},$$

in which the transmitted light-intensity is taken as 1. Opacity is the ratio,

$$\frac{\text{original light-intensity}}{\text{light-intensity transmitted}},$$

in which again the transmitted light-intensity is taken as 1. Plainly then in the case of the transparency (=1) of a completely transparent substance the opacity also = 1. The number representing opacity is the number of units of light that must fall on the medium in order that one unit of light may be transmitted.

The terms transparency and opacity are perhaps unfortunate in their implication of completeness, or, at any rate, high degree of the denoted quality. But as used in sensitometry they have not this emphasis, and Mr. Renwick has suggested replacing them by the respective terms, *transmittance* and *obstructrance*. The student, however, should now appreciate their mutual relation.

Opacities of a Negative.

It will have been clear from the above that the opacities of the series of deposits which form a negative are the values of chief concern in the use of the negative, since they represent the light-stopping powers. They represent what are popularly called the "densities" of the negative, and in a theoretically perfect negative are directly proportional to the light-intensities which produced them, since the time factor (the *t* of *i t*) is common to all these latter in the case of a plate uniformly exposed in the camera.

The Meaning of Density.

But the term density has a particular significance in sensitometry, following its first use in this sense by Hurter and Driffield. Density is a measure of the quantity of silver or other light-stopping material per unit area of a negative. It is a quantity, not a ratio as transparency or opacity is. It has a particular relation to these latter which perhaps can be best shown by a simple example.

Imagine a negative made by laying on a sheet of glass strips of developed film having a transparency of 1/3, *i.e.*, transmitting one-third of the light-intensity falling on it. Let the glass be uncovered on the left, then one thickness of film attached, then two thicknesses, then three thicknesses, the arrangement being as shown in fig. 3. Let us see what will be

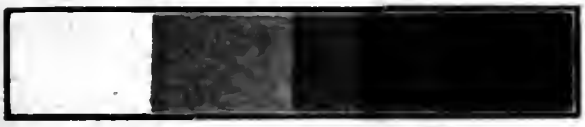

FIG. 3.—THE BASIS OF DENSITY.

The four deposits of the negative consist respectively of 0, 1, 2 and 3 thicknesses of film of a certain density.

the transparencies of these four patches. No. 1, being quite transparent, has a transparency of 1. No. 2 (one film) has a transparency of 1/3. What happens in the case of the two films? The first transmits one-third of the incident light and the second a third of this third, that is $1/3 \times 1/3 = 1/9$.

Index and Logarithm.

A little explanation must be put in here for the non-mathematical reader. It is one of the simplest mathematical forms to represent a value multiplied by itself any number of times by means of what is called an "index" (plural, indices) or "power." The index is written as a small figure placed slightly above, *e.g.*, 10×10 is written 10^2, and $10 \times 10 \times 10$ as 10^3, 2 and 3 being the respective indices. The value, in our example, is said to be raised to the power of 2, 3, or whatever the index is. Perhaps the best way of realising the nature of an index of any quantity is to think of it as the number of times that 1 is multiplied by that quantity. Thus:—

$3^3 = 1 \times 3 \times 3$. (Index is 2.)
$3^1 = 1 \times 3$. (Index is 1.)
$3^0 = 1 \times$ (no times 3) $= 1$. (Index is 0.)

Arithmetically an index must be a whole—you can't multiply a number by itself 2½ times by ordinary arithmetic—but mathematically an index is not limited in this way. It may be a fraction. A logarithm, which we shall need to employ directly, is simply an index or power. Hence its nature will be understood from what has just been said. Our $1/3 \times 1/3$, from which this digression started, is, of course, $(1/3)^2$. As we shall see directly, 2 is the logarithm of 1/9 to the base 1/3.

Relation of Density to Opacity.

To proceed now to the strip consisting of three thicknesses of silver deposit. Similarly it will transmit a third of a ninth, or $1/3 \times 1/3 \times 1/3 = (1/3)^3 = 1/27$. So we can write down the series of transparencies and the corresponding opacities as follows:—

No. of films	0	1	2	3
Transparency	1	1/3	1/9	1/27
Opacity	1	3	9	27
or	1 ($=3^0$)	$(3)^1$	$(3)^2$	$(3)^3$

Consider the third and fourth lines of this table. Neglecting the first column (those with some algebra will recognise that the 1 in line 4 may be written as 3^0), it is seen that we can express the opacities in a form in which a common number, 3, is successively raised to a power corresponding with the proportionate quantity of light-stopping material, *i.e.*, the silver deposit of the films. The silver (line 1) is in the proportion 1 : 2 : 3. The indices (line 4) are also 1, 2, 3. They simply indicate the number of 3's multiplied together, 1 (one 3) in col. 2; 2, (3×3) in col. 3; and 3, $(3 \times 3 \times 3)$ in col. 4.

But if the silver deposit in the two films be put all in one film, the transmitting effect will be the same; also the transmitting effect of three films will be the same if treble the quantity in a single film be contained in one film. Thus the indices 1, 2, 3 (line 4) are measures of the quantities of silver, *i.e.*, densities.

By comparing lines 3 and 4, we shall see the relation of density to opacity. It is that density is the logarithm of opacity. As mentioned in a preceding paragraph, a logarithm is an index or power. In $3^2 = 9$, 2 is the logarithm of 9 to the base 3 (written log$_3$ 9), that is the number of 3's which must be multiplied together to make 9. Similarly 1 and 3 are the logarithms of 3 and 27 respectively, in each case to the base 3. Any number, however, may be chosen for the base of a system of logarithms, and 10 is commonly selected in tables of logarithms which are published, *e.g.*, "Chamber's Mathematical Tables." Converted into logarithms to base 10, line 4 of our table will read:—

10^0 $10^{.477}$ $10^{.954}$ $10^{1.43}$ *

and the densities corresponding with the opacities in line 3 will be:—

Density	0	.477	.954	1.43

The density values employed in sensitometry are invariably computed on the above basis, that is, are logarithms of opacities to base 10. A density of 1 thus corresponds to an opacity of 10 or a transparency of 1/10. The density corresponding with any opacity is found by looking up the logarithm of the latter in a table of logarithms, but in measuring instruments, which invariably measure the proportion of light transmitted, and therefore measure its inverse or opacity, it is customary to graduate the scale in densities. This is done by marking on the scale the values of logarithms of the opacities instead of the opacity values.

Weight of Silver and Density.

There is not a simple method of measuring densities directly. Hurter and Driffield measured by chemical analysis the weight of silver (produced by development) per 100 sq. cm., which is required to give a density of 1 (opacity of 10), and found it to be .0121 gm. Subsequent measurements by Eder and by Mees of this *photometric constant*, as it is called, gave the values .0103 and .01035. Thus by use of this constant or multiplier, densities computed from optical measurements are expressed in terms of silver, *e.g.*, density of 1.2 = 1.2 × .0103 gm. silver per 100 sq. cms. = .0124. But we shall not have occasion to deal with densities expressed in this form, which is mentioned here only to show that the optically derived value (log opacity) is really a measure of density of silver deposit, just as the number of people per sq. mile is a measure of density of population.

Illustrations of Density.

Before leaving the definition of this all important property of density, perhaps an example may be given to show its logarithmic relation to opacity. Suppose a country to be so densely covered with pampas grass that an explorer by pushing through a region of it is exhausted to the degree that he can travel at only 1/10th of his previous rate. Suppose now that after regaining his full strength he comes into a region of equal extent, but having two grasses growing on an area where one grew in the first, and that his struggles to push through this denser region reduce his strength of progression to 1/100th. If we call the density of the first region 1 and of the second 2, we have a good illustration of density (as defined by Hurter and Driffield) and its relation to transparency.* Its relation to opacity is displayed by regarding the explorer as having a strength of 10 when entering the first region and of 100 when entering the second. These strengths being each brought to 1 by travelling through the respective regions, the numbers 10 and 100 are analogous to opacities. And if we multiply the densities each by the same suitable number (analogous to the photometric constant), we can express the densities of the regions in terms of the weight of the grasses on a given area.

A less fantastic illustration of density and opacity is provided by the simple optical device of a wedge of uniform substance, such as grey glass, or gelatine in which a fine pigment is evenly distributed. The density of such a wedge (Fig. 4) at any point is, therefore, measured by its thickness at that point, since the material is uniform. The densities

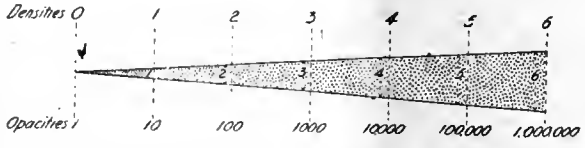

FIG. 4.—AN ILLUSTRATION OF DENSITY AND OPACITY.

The upper row of numbers represents the relative thickness of the light-obstructing medium. The lower row represents the corresponding opacities.

may, therefore, be represented by thickness numbers, which, in the wedge of fig. 4, run from 0 to 6. But if you hold such a wedge up to the light you see that towards its thicker end it becomes very opaque (" dense," as we commonly call it) indeed. That is what is denoted by opacity, and, as shown in the lower line of the figure, it increases by mathematical leaps and bounds as density proceeds sedately from its 0 to 6.

In short, and to clear the ground thoroughly for what follows, opacity is the degree to which a deposit of anything obstructs light, density is the quantity of the physical stuff—silver, pigment or anything else—of which that deposit is made. When you hold up a negative to the light, you judge its opacities; you can't judge its densities.

The Relation of Densities to the Tones in the Subject.

It will now be seen, from a comparison of the definition of a theoretically perfect negative (in the opening paragraphs of this chapter) with the relation of density to opacity to which we have now come, that we can set down the relation which the densities must bear to the light-intensities emitted by the subject in order that the negative may be theoretically perfect.

The opacities, as we have seen, require to be proportional to the light-intensities.

In the making of a negative in a camera the exposures (light-intensities × time, *i.e.*, $I\ t$) which the various parts of the plate receive are proportional to the light intensities, since all these latter act for the same time t. Therefore the opacities of the negative require to be proportional to these exposures.

But as the densities are the logarithms of the opacities, it follows that the relation between the densities requires to be the same as the relation between the logarithms of the exposures. This relation is that the difference between any two densities shall be equal to the difference between the two corresponding log exposures. I may illustrate this relation by reference to the Egyptian landscape (Fig. 1). The assumed light-intensities are:—

Light-intensities	20	12	8	4	1

which are proportional to the exposures of the parts of the plate representing sky, foreground, pyramid and sphinx. So we can write:—

Exposures	20	12	8	4	1

In a theoretically perfect negative the opacities will be, say:—

Opacities	40	24	16	8	2

representing densities (log opacities) of:—

Densities	1.602	1.380	1.204	.903	.301
	.222	.176	.301	.602	

The figure in the smaller type between each density and the next is the difference between the two. It will be seen that these are the same as those between the logs of the corresponding exposures, viz.:—

Log exposures ...	1.301	1.079	.903	.602	0
	.222	.176	.301	.602	

It is this equality of difference between logs of corresponding quantities which Hurter and Driffield, in common with mathematicians, speak of as proportionality. They mean this relation when they define the theoretically perfect negative as one in which the densities " are proportional to the logarithms of the intensities of light proceeding from different parts of the subject." (H and D. Memorial Volume, p. 78.) " Proportional " is used by the mathematicians as a contraction for the difference-relation when speaking of logarithms; but, in default of apprehension of this extra-ordinary meaning of the word, the custom, which is generally followed by writers on sensitometry, must be very confusing to the beginner who is trying to master the fundamentals of the H. and D. doctrine.

It should, however, be clear from the above what is the theoretical basis of a correct negative—that is to say, for any difference between the *logarithms* of the two numbers representing the different exposures on different parts of a plate, there shall be an equal difference between the *densities* produced by those exposures.

But can this condition be fulfilled in the making of negatives on dry plates? For the answer we must now proceed to consider the laws which by experiment have been found to govern the action of exposure and development and see within what limits the above condition of correct reproduction can be realised.

In proceeding to this part of the subject it should be pointed out that in sensitometric tests it is customary to increase exposures in multiple (2 as a rule), so that the difference between successive log exposures is the same. Thus:—

Exposures	1	2	4	8	16
Log exposures ..	0	.301	.602	.903	1.204

The common difference is .301, and in the theoretically perfect negative the densities produced by the above exposures would likewise differ by .301.

G. E. B.

(To be continued.)

* It may be rightly objected that two numbers do not serve to distiagnish, in this analogy, between a difference and a ratio. Will the reader, therefore, please assume a third region, of 3 grasses per unit-area, in passing through which my intrepid traveller's full vigour is reduced to 1-1000th.

PERMANGANATE FORMULÆ.

The majority of photographers do not realise how adaptable permanganate of potash is to the needs of the general worker.

This salt of potassium may be used for a variety of purposes, and it will be found that baths compounded with permanganate will compare favourably with other formulæ used for a like purpose, and in some cases excel them.

The object of this article is to collate the formulæ for various baths, of which permanganate is the principal agent, and also the processes for which the salt may be used.

Negative Reducer.

As a reducer for negatives this salt has proved valuable. Negatives that have been inadvertently allowed to develop a little too much may be as easily reduced to the required density as the excessively over-developed ones. A strong solution for rapidly reducing the most dense negative is

Potassium permanganate (5% sol.)	...	2 drs.
Sulphuric acid (10% sol.)	...	5 drs.
Water	...	10 ozs.

Apply this solution to a dry negative, wash immediately and dry. Again repeat this procedure, and a considerable softening of contrasts is obtained.

On the other hand, fairly even reduction may be obtained by diluting the above reducer to 60 ozs. and applying to a wet negative.

The strong reducer should not be used to reduce a negative with strong high-lights and shadow detail in clear gelatine, as the little deposit in the shadows will be removed, as they would be with any single solution reducer when considerable reduction is desired in the high-lights.

Stain Remover.

No matter how careful one may be, occasionally stains make their appearance on our negatives, but with the aid of an acid permanganate solution the fault may be rectified with ease.

Two methods may be adopted, one of which will permit the negative to be intensified during the process of removing the stain. Bleach the negative in either A, B, or C, solution of the late Welborne Piper's chromium intensifier according to the degree of intensification required. Wash, away from strong light, until the bichromate stain is removed, place the negative in

Potassium permanganate (5% sol.)	...	2 drs
Sulphuric acid (10% sol.)	...	5 drs
Water	...	5 ozs

from 2 to 10 minutes until the stain is removed. The negative will have taken on a characteristic brown stain which can be easily removed with a 1 in 10 bisulphite lye or a 2 per cent. potassium metabisulphite solution.

Pour either of these solutions on and off the negative until the stain is removed, but discard the clearing bath when any discolouration is visible, and use fresh solution. Wash the plate for a few minutes and develop with a normal amidol developer to complete the process.

The second method and the more direct for removing pyro stains is the formula published by Ilford, Ltd., in the "B J.," May 5, 1916, providing no intensification of the negative is required.

Soak the negative for 10 minutes with constant rocking of the dish in

Potassium permanganate	...	50 grs
Common salt	...	½ oz.
Acetic acid (glacial)	...	1 oz.
Water	...	20 ozs

wash briefly and transfer to

Potassium metabisulphite	...	1 oz.
Water	...	20 ozs.

until the bleached image is quite white everywhere to the back of the film.

Re-develop the image in any non-staining developer such as amidol, when a good neutral black deposit with clean shadows is produced.

If the negative has not been dried before the treatment is applied, harden the negative in a solution of

Chrome alum	...	10 grs.
Water	...	10 ozs.

as the film is liable to become a little more tender in the process.

Bleacher for Sulphide Toning.

Probably the best known formula containing potassium permanganate is the one popularised by Mr. T. H. Greenall for bleaching prints previous to toning by a solution of sodium sulphide. Many words have been written eulogising this bleacher, and with justice. It has the power of clearing up the high-lights and tones a correctly developed print to a pleasing cool brown colour quite free from any trace of yellow. The writer prefers the acid bleacher, as it is less trouble to compound than the formula containing sodium chloride, and the remarks in the previous paragraph apply to that formula.

Two stock solutions are required :—

A. Hydrochloric acid	... 10%.
B Potassium permanganate	... 5%.

For use, take A 1 oz. and B 30 mins.

This formula is considerably stronger than the one suggested by Mr Greenall, but it has been found necessary, to complete the bleaching within a reasonable time

Both stock solutions keep indefinitely in stoppered bottles, but the working mixture must be made up at the time of using and discarded when it shows any sign of discolouration or turbidity, as trouble may be experienced where the sediment which is formed touches the print.

The prints are transferred direct to the sulphide bath, which should not be stronger than 2 grs. to the ounce, where any brown stain due to the bleaching bath will generally disappear. Should the sulphide bath fail to remove the permanganate stain, a quite effective clearing bath is 1 per cent. solution of potassium metabisulphite.

Re-bleaching Sulphide Toned Prints.

It sometimes happens that a sulphide toned print is not quite the colour desired, particularly so when the exposure of the print, for the reason of excessive contrasts in the negative, has had to be increased and development not carried out to the limit. When it is deemed desirable to improve the colour of any sulphide toned print resort may be made to the bleaching bath already given, and it will be found to bleach out nearly as rapidly as a normal print. Apply a weak solution of sulphide (about 1 gr. to 1 oz. water) to the print, and a darker and much improved colour will be the result.

Should, however, it be desired to reconvert a sulphide toned print to a black tone, use the same bleacher and re-develop the print in the following acid amidol developer. —

Sodium sulphite	...	½ oz
Potassium metabisulphite	...	80 grs.
Amidol	...	30 grs.
Water	...	20 ozs.

pass through the hypo bath, then wash and dry.

Re-development for Improving Prints.

This useful salt may be also used for bleaching a bromide or gaslight print to improve the colour and contrast

It not infrequently happens that an enlargement has to be made from a negative with excessive gradations, and resort is made to abnormal exposure and development. The bad colour of the print show the method of its production.

Prints of this type can be readily improved and a warm

black tone obtained on most bromide papers by the following method:—

Bleach the print in	
Potassium permanganate, 5%	120 mins.
Sulphuric acid, 10	40 mins.
Sodium chloride	30 grs.
Water	10 ozs.

Wash the print for 10 minutes and re-develop in strong daylight with a normal amidol developer without any addition of bromide. Wash the print again for a short period, and the process is complete.

Slight intensification is obtained by this method, but should this increase in strength be deemed insufficient greater intensification can be obtained by first sulphide-toning the print, washing, re-bleaching and re-developing in the formulæ already given in an earlier portion of this article.

Hypo Elimination.

The rapid elimination of hypo is occasionally necessary, and no better chemical can be used than permanganate of potash. Rinse the negative for a short time in running water, and meanwhile make up a solution of permanganate of potash of a pink colour. Lay the negative in a dish and pour on a small quantity of the above solution, which must be removed so soon as the pink colour is altered. Repeat this procedure with fresh solution until the colour of the permanganate solution is not discharged.

Pyro Stained Fingers.

Immerse fingers in Ilford bleacher, already mentioned, for a short period of time, and remove permanganate stain with the metabisulphite solution.

Hypo Test.

Permanganate may be also used to test the presence of hypo in negatives or prints. For this delicate test make up a solution of potassium permanganate of a light rose colour and place a small quantity in two test tubes, or other glass vessels. In one tube allow the drippings from the negative or print to be tested to fall into the solution; if no change of colour is apparent when compared with the untouched solution you may be assured that the negative is free from hypo.

The dilute solution for this test should be used soon after mixing owing to the water causing the solution to lose colour.

HORACE C. INSKEEP.

FRAMING THE PICTURE.

[In spite of the great popularity of the *passe-partout* method of finishing photographs and other pictures, the older plan of framing in mouldings still holds its own, particularly among professional workers. The following hints, which we take from our contemporary, "American Photography," will no doubt be read with interest, they being given by a worker who has studied the subject of mounting and framing very closely, and whose examples of work are very well known in artistic circles.—EDS. "B.J."]

MUCH has been said about making enlargements from really good negatives, but unless some of these enlargements are framed and hung on walls much pleasure is lost. If the prints are taken to the local framing shop the maker should know whether or not his picture needs a mount; if so, how wide and what colour; also something about the width of the frame and what colour it should be. This knowledge is more useful if one attempts to make the frame, whether he makes the moulding or buys it and simply cuts it to correct lengths.

To frame a picture that is not beautiful is to honour what should be ignored. Much has been written about composition, so let us make use of whatever knowledge we may have on the subject, in selecting the portion of our negative to enlarge. Study a contact print, go over it with a pair of L-shaped cards, and select the composition, enlarge the corresponding portion of your negative, and then the following hints may be of value in framing it.

The functions of the mount are to increase the size of the picture space upon the wall, and to isolate it from the surrounding background. A picture with a great deal of action requires a mount, as the frame alone is not enough to bind the picture together and separate it from the background. Prints tinted with water-colours, and prints resembling Japanese prints in composition, need something more than the frame between them and the wall. In some pictures the figure comes close to the top, and seems crushed or at least crowded without a mount. Again, the figure may be cut on the sides, and a mount is needed. When a picture is filled with large objects and is to be viewed at a distance, a mount is generally required to isolate it. If the picture is filled with detail, and to be viewed at close range, no mount is required.

The shape of the picture determines the shape of the mount. A horizontal picture should be framed on a horizontal mount; a vertical one upon a vertical mount; and a square one upon a mount made slightly oblong by making the square below the picture wider than that above. Avoid squareness in either picture or mount; an oblong is much less monotonous, and therefore much more pleasing. Simple multiples in the dimensions of the oblong are to be avoided; that is, the ratio of the sides should not be 1 to 2, 2 to 3, or any similar even ratio, but should have a more subtle relation.

The picture should neither be crowded nor lost in space. There should always be a wider margin below than above giving a feeling of rest. The side margins should be equal, and can be the same as the top, or a little more or less, governed by the action in the picture. Much horizontal action requires more space at the sides than at the top, but the general rule is that the widest space should be at the bottom, next at the top, and narrowest at the sides. Much action in the picture calls for a larger mount, and a quiet one calls for a smaller mount. A number of large objects in a picture makes a larger mount necessary. The mount should give the appearance of rest to the picture. Avoid oval, diamond-shaped, or any odd-shaped mounts.

Sometimes a second mount, forming a narrow band $\frac{1}{8}$ in. to $\frac{1}{4}$ in. wide around the picture, and of a colour to harmonise with the dominating note in the picture, heightens the effect, and gives sparkle and beauty. Do not allow a strip of pure white to enclose the picture. Sometimes a single line of the value of the darks in the picture, drawn upon the mount about $\frac{1}{4}$ in. from the picture, softens the contrast between the two. An opening may be cut in the mount, the size of the picture, giving a soft-border line formed by the shadow of the mount.

Any picture in brown tones should have a mount of the same tonal quality as the picture; that is, neither warmer nor colder, and in value slightly above the middle value of the picture and one tone lighter than the frame. Gray pictures should have grey mounts, above the middle greys of the picture and of the same quality. Pictures tinted with water-colours require a cream or dull gold mount.

The frame may be considered as a part of the decorative scheme which the picture will make when hung, or a strong enclosing form which will separate the picture from the objects around it. The frame is only a continuation of the mount,

if one has been used, and should be unobtrusive. Any frame that detracts from the picture is wrong. For this reason mouldings should not be used in which the grain is too coarse or prominent. As a rule, the colour of the frame is the same as the mount, or the predominating colour of the picture, but lighter than the darkest parts and darker than the lightest parts. In some respects the frame is to the picture what dress is to people. The frame should modestly enhance the beauty of the picture, and be subordinate to it. One of the primary purposes of the frame is to protect the picture, hence a durable wood should be used, rather than a plaster combination. Ornately carved and glittering mouldings are harmful to the tone relations of the picture, and violate the principles of subordination. Whenever possible, there should be harmony, symbolic or otherwise, between picture and frame. When the frame is sufficient to isolate the picture, no mount should be used.

A consistently pleasing relation must exist between the width of the mount and that of the frame. The moulding is usually narrower than the mount, never the same width. The width is governed by three things: the amount of action in the picture, the number and size of the objects in it, and the brilliancy of the colouring. The stronger the action, the stronger the frame. Large objects in the picture require a wider frame than several small objects would. Single heads in repose need a wider frame than two or three small figures. In case of a tinted photograph, great contrast in hue or intensity requires a wider moulding than quiet contrasts.

In mouldings wood appears stronger the more it is cut up. A flat moulding is suitable for a picture flat in colour or strong in feeling. A moulding with depth is appropriate for a landscape showing perspective. The curve and the depth of the wood accentuate the impression of distance. Where there is much action or great strength shown, a more complicated moulding, made of two or more bands, may be used.

For the majority of pictures in brown use flat mouldings, or those with slight curves, finished to show the grain of the wood but slightly. The frame should be toned to the right hue and value to harmonise with the picture—lighter than the darkest parts and darker than the lightest parts—with perhaps a delicate beading for accent. The beading, if used, may be a dull gold, but never a bright, shiny gold. A small photograph in sepia looks well in a narrow gilt frame toned toward sepia. For photographs tinted in colours use a dull gilt moulding, usually narrow. Or, what is better, tone the gilt to sepia, or green, or grey, depending upon the predominating colour in the tinted picture. Green or grey-toned frames can be used with pictures cold in colouring, and sepia-toned gilt frames with warm-toned pictures. For pictures in black and white, or half tones of grey, grey moulding should be used, governed by the same considerations as brown mouldings for sepia prints.

A fine-grained wood is best for frames—white pine, poplar, cherry, well-seasoned red gum, walnut, mahogany, maple, fine-grained oak. Maple is good for grey effects. Mahogany is good where it can be stained brown to harmonise properly. Gum and walnut may be left natural or stained to a darker brown. The cheaper woods can be enamelled the proper shade.

In case one is attempting to refinish a moulding to more closely harmonise with the picture, use artists' oil colours, of a proper shade or mixture to tone the original colour to the proper shade. Thin the colour slightly and rub on the wood with a soft cloth until the desired shade is obtained. If the moulding has never been finished, the artists' colours may be mixed to the proper colour, and thinned with turpentine and used for the entire stain, or some prepared oil stain may be used, if the proper colour can be found. For tinted photographs the ordinary gold bronze may be used alone, or toned to harmonise with the predominating colour, as mentioned above. This is done by first staining the wood with the oil colours, and then, when nearly dry, rubbing the dry gold bronze into the colour, letting just a trace of the colour show through. Aluminium bronze may be used in this way for cool, grey effects. On some pictures a frame made of open-grained wood may be used, stained to the proper colour and then neutralised by rubbing a white filler into the open grain. The final finish on any frame should be flat or rubbed dull, never glossy. Wax is an appropriate finish.

When the frame is finished, the next thing is to put in the picture. Cut the glass and backing to fit the frame accurately, and then make sure the glass is clean. Use glass that is clear in colour and free from air bubbles or noticeable waves. Place the glass, picture and backing in the frame and fasten in securely with brads, laying them flat on the backing to start them. Then make the frame dust-proof by covering the back with a heavy piece of wrapping paper. Dampen one side of the paper with a moist cloth, and spread a thin layer of glue over the back of the moulding. Lay the paper on the moulding wet side up, press firmly to the moulding and stretch toward the outside of the frame until the wrinkles are practically gone and the paper seems quite taut. Let it dry and trim the edges of the paper that project over the edge of the frame.

Place screw-eyes not more than 2 in. from the top of the frame, as the picture should hang as flat as possible. If the picture is at all large, two wires should be used, each running vertically from the frame to the picture moulding of the room. The triangular space made by a single wire running to the ceiling and down to the other side of the frame is not in keeping with the vertical lines of the room. The wall on which the picture is to be hung should be considered as a complete composition, and the picture so hung that the space is well balanced.

GILMAN LANE.

HALF WATT LAMPS IN FILM STUDIO LIGHTING.

(A communication from the General Electric Co.)

THE gas filled metallic filament lamp is rapidly growing in favour as an illuminant for portrait studio lighting, but its use in the production of cinematograph films has not been developed to the extent which it deserves. An account of some experiments in

Fig. 1.

this direction recently made with Osram gas filled lamps in the studios of Messrs. Holams, Ltd., may be of interest.

The orthochromatism of modern films, by which colours are given their true relative tone values when exposed in daylight, is of little advantage when the exposure is made under arc lamps owing to the predominance of blue and blue violet rays in these lamps. In the gas filled lamp, however, the photographer has a light source rich in red, orange, and yellow rays. The resultant light is therefore a much closer approximation to daylight, and the images on standard orthochromatic film are also more colour true.

In the tests mentioned above, a large number of models and colour schemes were photographed, and it was found that it was necessary for the artistes to use little or no make up other than that necessary for special character effects.

The illustrations reproduced herewith are sections of films of the same scene taken on the same day under exactly identical

conditions, the one under arc lamps and the other under the light from Osram gas-filled lamps. The colour scheme was purposely made as rich and comprehensive as possible so as to present a really difficult subject. The background consisted of three panels—in the centre, an Indian rug having a warm pattern of red, yellow, green and blue. The side panels were of rose red velvet and black and yellow striped silk respectively. The sitter was also a somewhat difficult subject, being fair with light brown hair and blue grey eyes. Her dress was of natural shantung with navy-blue collar and cuffs.

Fig. 1 was taken with 12 enclosed arc lamps taking 15 amperes each at 200 volts, a total of 36 kilowatts.

Fig. 2 was taken immediately afterward with 16 1,500-watt Osram gas filled lamps in G.E.C. studio reflectors, and consuming in all 24 kilowatts.

The improved colour rendering in fig. 2 is obvious.

The results of these experiments tend to show that the gas-filled lamp is worthy to play a much larger part in film production than hitherto from the point of view of film-quality alone. They have, however, many other inherent advantages.

They are very light and easily handled so that replacements can be made quickly. Moreover, the absence of complicated

Fig. 2.

mechanism makes for simplicity of operation and low cost of supervision and maintenance. A very small staff of electricians would be needed for the largest installation.

Gas-filled lamps are obtainable for all standard voltages, and are suitable for both alternating and direct-current circuits. No energy, therefore, is wasted in resistances and no expensive converters are necessary.

Other valuable features are that the quality of the light does not vary appreciably throughout the life of the lamp, reaches its full value immediately the lamp is switched on, and is perfectly steady.

Finally, the question may arise as to the dazzling effect of the intensely brilliant gas-filled lamps, but if these are installed with large white reflectors behind and suitable diffusers in front the glare is not any greater than that of the usual arrangement of arc lamps, and, moreover, it is probably more bearable on account of its steadiness.

TYPEWRITING FOR PHOTOGRAPHIC REPRODUCTION.—In making duplicate copies of manuscripts having inset illustrations, or in reproducing specifications, the blue-print process is often the most convenient. To letter a considerable quantity of text is tedious (says "Popular Mechanics"), and, if properly done on a typewriter, the result will be more satisfactory. Tracing cloth, or tracing paper, preferably of the unglazed onion-skin variety, may be used. In writing the text on the typewriter, reverse a piece of carbon paper under the tracing paper, so that the impression is made on both sides of the sheet. This will give density, and make the blue-prints sharp. If white grounds with dark lines are desired, a new sheet of carbon paper should be used, and this taken as the negative in making the prints. Bromide or gaslight paper may, of course, be used in place of the ferroprussiate paper.

Exhibitions.

X-RAY PHOTOGRAPHS AT THE ROYAL PHOTOGRAPHIC SOCIETY.

AN important exhibition of X-ray photographs has just been opened at the House of the Royal Photographic Society, 35, Russell Square, W.C., under the auspices of the Röntgen Society. Comprising upwards of 250 prints it includes a number of examples from French workers. The French prints arrived by special aeroplane from Paris only on the day prior to the opening of the exhibition, and for this reason it was not possible to include the details in the official catalogue, but where available short descriptive notes are attached to the prints. Of especial interest in this section is the work of the late Dr. C. Infroit, of the Hospice de la Salpêtrière, Paris. It will be remembered that this worker died recently, a martyr to science. Drs. Vignal, Haret and Contremontez have sent very striking examples of their radiographic work, and interesting examples of metal radiography have been contributed by the firm of Giaffe-Gallot and Pilon.

Among notable examples of work contributed by radiographers in our own country is a fine series of prints illustrating various abnormalities of the vermiform appendix, by Dr. C. Thurstan Holland, and the Cancer Hospital is represented by some good technical prints, noteworthy being a record of the progress of opaque meals.

The wide application of radiography is demonstrated by the prints of paintings shown by Dr. A. Chèron and the Sunic Research Laboratory; as is widely known nowadays, fraud is readily detected and curiosities brought to light by its use.

Undoubtedly of historic interest are the photographs of the hands of celebrities taken in the early days of X-ray photography (1896) by A. Campbell Swinton, Esq. The hands shown here are those of Lord Salisbury, Sir William Crookes, Lord Armstrong, Lord Kelvin and the Rt. Hon. A. J. Balfour, O.M.

Dr. Salmond, joint honorary secretary of the Röntgen Society, is represented by work of good technical quality, and radiographers will be particularly interested in the comparative results obtained with the new Impex plates and the ordinary X-ray plates by Dr. G. H. Rodman, the President of the Royal Photographic Society. The increased rapidity secured by the Impex plates is clearly indicated.

A series of plates taken under the difficulties of war and with a portable apparatus by Miss Phyllis Berry and Miss Collum, of the Scottish Women's Hospital, France, illustrates some of the war-time applications of the X-ray.

The exhibition generally is one of very considerable technical excellence, and a distinct advance over anything previously seen. The hanging of the work of radiographers in this country alongside that of workers in other countries demonstrates the advantage of different methods of procedure, and should serve to help technique in the future. Perhaps the best evidence of this is seen in a series of sets of four prints produced by lay workers employed either in the radiographic departments of hospitals or acting as assistants to qualified radiographers.

A competition for prizes offered by Dr. R. Knox, President of the Röntgen Society, has undoubtedly helped in popularising this exhibition, and generally the entries are of a high standard. The work of Mr. Suggars, of the London Hospital, was the best, in the opinion of the judge, and it was closely followed by that of Mr. A. O. Forder, of King's College Hospital.

The exhibition will remain open daily during the whole of June (Sundays excepted), from 11 a.m. to 5 p.m., admission free, and should certainly not be missed by anyone interested in radiography

---

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Applications, May 23 to 28 :—

DAYLIGHT LOADING.—No. 14,596. Combined daylight-loading roll-film or plate-holder for photographic cameras. J. W. Willans.

COMBINATION PHOTOGRAPHS.—No. 14,572. Method of producing combination photographic pictures. W. H. Pearse.

CAMERAS.—No. 14,796. Photographic cameras. E. G. Hughes.

PAPERS.—No. 14,549. Means for manufacture of photographic papers. J. W. Davies.

FERROTYPE PLATES.—No. 14,823. Holding and lifting ferrotype photographic plates. G. P. Usher.

STEREOSCOPY.—No. 14,827. Method of producing increased speed and stereoscopic or relief effect in photographic plates or films. F. W. Daniels.

CINEMATOGRAPHY.—No. 14,477. Cinematograph films. W. Ayer.

CINEMATOGRAPHY.—No. 14,420. Cinematographic cameras. J. B. Barton and Sir O. Stoll.

CINEMATOGRAPHY.—No. 14,421. Cinematographic projectors. J. B. Barton and Sir O. Stoll.

CINEMATOGRAPHY.—No. 14,732. Means for taking, printing and projecting films. J. V. Davies.

CINEMATOGRAPHS.—No. 14,832. Cinematographs. Educational Film Co.

X-RAY APPARATUS.—No. 14,563. X ray apparatus. General Electric Co.

FRAMES.—No. 14,894.—Photograph frames. J. Glover.

CINEMATOGRAPHY.—No. 14,280. Cinematograph film feed and take-up sprockets. A. Kur.

REPRODUCTION METHOD.—No. 14,341. Photographic reproduction of pictures represented on curved surfaces. G. von Lücken.

PHOTOGRAPHIC RECORDS.—No. 14,631. Photo-recording tachymeters. F. Rived.

CINEMATOGRAPHY.—No. 14,533. Cinematograph machines for advertising. W. E. G. Smithers.

STEREOSCOPIC CINEMATOGRAPHY.—No. 14,293 (or 14,239). Stereoscopic shutter for cinematograph projector. H. P. Tucker and W. Waugh.

CINEMATOGRAPHY.—No. 14,463. Cinematography. C. H. Verity.

CINEMATOGRAPHS.—No. 14,832. Cinematographs. G. C. A. and M. J. G. da Vrière de Lodi.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TRIPLET LENSES.—No. 161,091 (June 5, 1920). The invention relates to objectives primarily for use in photography, and has for its subject an objective by means of which a sharp image will be produced. The objective is composed of a small number of lenses and is designed to give a plastic image, focally correct. According to the invention the objective is composed of three separate lenses, which are separated one from another by air-gaps and arranged in the form of two lens systems. The concave surfaces of the lenses in contact with the air-gaps are directed towards the diaphragm, which is disposed between the two lens systems. One lens consists of a convex-concave dispersive lens and of a concavo-convex collecting lens separated one from another by an air gap and having their concave surfaces turned towards the diaphragm. The second lens system is composed of a biconcave lens and of a biconvex lens cemented together along a collecting surface.

In order to obtain a sharp image, a large picture-field with anastigmatic flattening of the field, efficient orthoscopy, reductions of the spherical and chromatic aberrations and consequently a focally correct plastic image, and in order to permit of the use of three different focal lengths in a single objective the convex-concave dispersive lens has a greater thickness at the centre than the biconcave lens, whilst each of the two systems, separated by the diaphragm, has a collecting effect. An objective of this very simple construction has, with the glass types at present obtainable, a small residuum error of chromatic magnification, which is, however, not disturbing if the objective is used for amateur purposes. If the objective is designed to be used for high-grade technical purposes the error is avoided by forming the convex-concave dispersive lens of a positive lens and of a negative lens cemented together. The types of glass used are chosen so that the positive lens possesses less dispersive power than the negative lens. The refractive indices may either be the same or different according to the purpose in view.

The construction of the objective thus constructed may be modified according to requirements and according to the purpose for which it is to be used. The type of glass, the radii and the thicknesses may be varied as required.

Three forms of construction are described by way of example in the accompanying drawings. Each form serves a different purpose.

Similar reference letters designate similar parts in all figures. The diaphragm is indicated by the line B—B. In Fig. 1, L_1 is

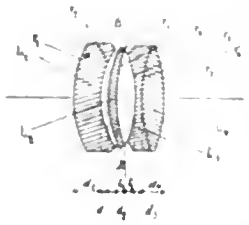

Fig. 1.

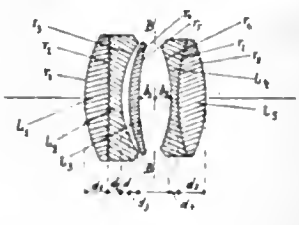

Fig. 2.

the convex-concave dispersive lens and L_2 the concavo-convex collecting lens. L_3 is the biconcave lens and L_4 the biconvex lens. The curved surfaces of the lenses are indicated by r_1, r_2 and so forth, whilst d_1, d_2 . . . . . are their thicknesses, and b_1, b_2 indicate the widths of the air gaps between the lenses. The types of glass of the various lenses are given by the refractive index n_D for the D line of Fraunhofer spectrum, n_G^1 being the refractive index for the G' line of the same spectrum.

In this form of construction the objective is designed for a focal length of 300 mm. The free aperture is 43 mm., the ratio of aperture to the focal length being consequently 1 : 7. The angle of view is greater than 90 deg. This is the simplest form of construction, as the objective is only composed of four single lens elements. The two lens systems of the objective, separated by the diaphragm, have a positive focal length, the front system having the longer focal length. The following particulars apply to an objective having a focal length of 100 mm. :—

Radii of curved surfaces.		Thicknesses and air-gaps.	
r_1	= 16.03 mm.	d_1	= 3.799 mm.
r_2	= 11.62 mm.	d	= 0.534 mm.
r_3	= 15.36 mm.	d_1	= 1.202 mm.
r_4	= 21.76 mm.	$b_1 = b_2$	= 1.336 mm.
r_5	= 17.36 mm.	d_3	= 0.801 mm.
r_6	= 20.03 mm.	d_4	= 2.871 mm.
r_7	= 18.03 mm.		

Glass types.

$L_1 = L_2$	n_D 1.53980	n_G^1	= 1.55159
$L_3 = L_4$	n_D 1.62070	n_G^1	= 1.63463

In Figs 2 and 3 the collecting lens of less dispersion than that shown in the foregoing example is indicated by L_1, L_2 being the dispersive lens of greater dispersion cemented to L_1. The concavo-convex collecting lens is indicated by L_3, L_4 being the biconcave dispersive lens and L_5 the biconvex collecting lens.

In Fig. 2 the objective is designed for a focal length of 300 mm. The free aperture is 50 mm., the ratio of aperture to focal length being consequently 1 : 6. The angle of view is 90 deg. The objective consists of five lens elements, the convex-concave dispersive lens being composed of the lens L_1 and of the lens L_2, which are connected together along a plane surface. The glass types for L_1 and for L_2 have for D approximately the same refractive index, but the dispersions are different. The front lens system of the objective possesses the larger focal length.

The following particulars apply to an objective having a focal length of 100 mm. :—

Radii of curved surfaces.	Thicknesses and air gaps.
$r_1 = +18.02$ mm.	$d_1 = 3.37$ mm.
$r_2 =$ plane	$d_2 = 1.42$ mm.
$r_3 = +12.91$ mm.	$d = 0.72$ mm.
$r_4 = +18.14$ mm.	$d_3 = 1.30$ mm.
$r_5 = -29.64$ mm.	$b_1 = b_2 = 2.02$ mm.
$r_6 = -17.25$ mm.	$d_4 = 0.94$ mm.
$r_7 = +25.61$ mm	$d_5 = 3.34$ mm.
$r_8 = -18.53$ mm.	

Glass types :

L_1 : $n_D = 1.57190$	$n_G{}^1$	$= 1.58460$
L_2 : $n_D = 1.57180$	$n_G{}^1$	$= 1.58643$
$L_3 = L_5$: $n_D = 1.61650$	$n_G{}^1$	$= 1.63113$
L_4 : $n_D = 1.54440$	$n_G{}^1$	$= 1.55971$

In Fig. 3 the objective has a focal length of 300 mm. The free aperture is 60 mm. The ratio of aperture to the focal length is therefore 1 : 5. The angle of view is 80 deg.. The convex-concave dispersive lens is composed of the lens L, and of the

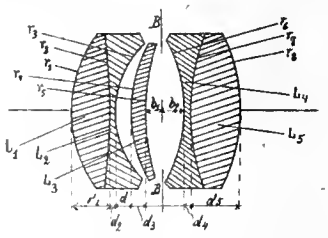

Fig. 3

lens L_2, which have different refractive indices as well as different dispersions. The front lens system has a smaller focal length than the rear lens system (L_4, L_5). An objective of a focal length of 100 mm. has the following dimensions :—

Radii of the curved surfaces.	Thicknesses and air-gaps.
$r_1 = +16.92$ mm.	$d_1 = 4.98$ mm.
$r_2 = -54.76$ mm.	$d_2 = 1.00$ mm.
$r_3 = +12.30$ mm.	$d = 1.80$ mm.
$r_4 = +18.92$ mm.	$d_3 = 1.98$ mm.
$r_5 = +29.87$ mm.	$b_1 = b_2 = 2.49$ mm.
$r_6 = -18.92$ mm.	$d_4 = 1.00$ mm.
$r_7 = +29.87$ mm.	$d_5 = 6.96$ mm.
$r_8 = -22.90$ mm.	

Glass types :

—Paul Rudolph, Grün, nr. Lengenfeld, Vogtland, Germany.

Background Stands.—No. 160,539 (December 20, 1919). Background apparatus for studio portraiture comprises several backgrounds carried by rollers a, Figs. 1 and 2, which are mounted

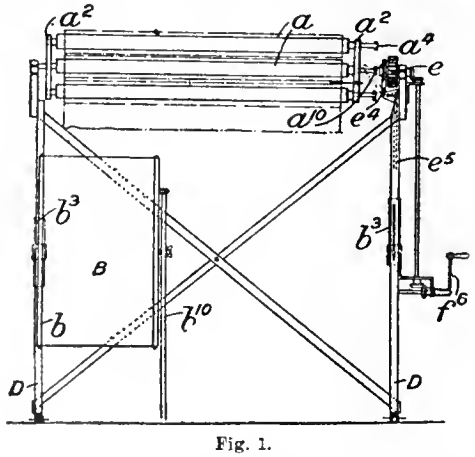

Fig. 1.

on a rotating holder a^2 and normally prevented from unrolling by springs a^5, Fig. 4. The holder a^2 is rotated by bevel-gearing from the handle f^6 through a gear-wheel a^{10} and pinion wheel e on a countershaft E. When the required background is brought into position in alignment with the countershaft E, the wheel e can be moved along the countershaft by a depending handle e^5 and crank-arm e^4, disengaged from the gear a^{10} and engaged with the projecting end a^4 of the selected roller, and the background unrolled from the same handle f^6. The ends of the rollers a may alternatively carry bevel gears, and a chain or pulley gearing

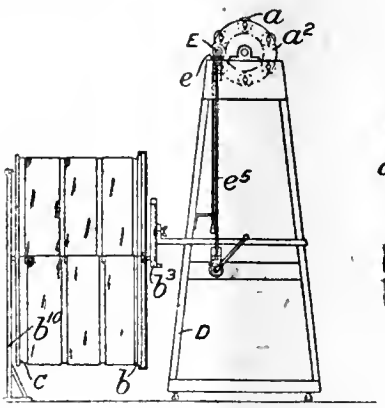

Fig. 2.

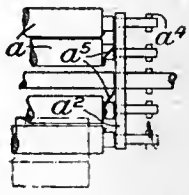

Fig. 4.

substituted for the bevel-gearing, provision being made for the countershaft E to engage recesses in the holder a^2. Reflecting or diffusing screens B, C on spring rollers b are mounted between a frame b^{10} and a bracket b^3, secured to the background frame D. Provision is made for a vertical and angular adjustment of the reflector or diffusing-screen.—J. H. Greenwood, 33, North Valley Road, Colne, Lancs.

The following complete specifications are open to public inspection before acceptance :—

Cinematography.—No. 163,676. Optical device for compensating the movement of the film in cinematograph apparatus. Petra Akt.-Ges. für Elektromechanik.

Cinematography.—No. 163,677. Film guiding for the optical compensation of the movement of the film in cinematographs. Petra Akt.-Ges. für Elektromechanik.

Cinematography.—No. 163,678. Optical compensation of the motion of the film in cinematographs. Petra Akt.-Ges. für Elektromechanik.

Projection Apparatus.—No. 163,687. Projection apparatus. L. Marzocchi.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Wellington (Child Design).—No. 412,402. Photographic plates, films and chemicals. Wellington and Ward, Shenley Road, Boreham Wood, Elstree, Hertfordshire, manufacturers. February 11, 1921.

Eclipse.—No. 413,813. Photographic plates and photographic films. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W.2, manufacturers of photographic materials.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

Ufag.—No. 383,896. Sensitised films for photography. Universum-Film Aktiengesellschaft, Unter den Linden, 56, Berlin, Germany, manufacturers.

Mr. Pirie Macdonald, of New York, who was invited by the Edinburgh Society of Professional Photographers to a luncheon, has written to the President (Mr. E. D. Young) regretting his inability to accept the invitation, as his visit to Edinburgh has been cancelled.

New Books.

The Film Industry. By Davidson Boughey. London: Sir Isaac Pitman. 3s. net.

THERE is, no doubt, a large section of the public which is interested in being behind the scenes in the production of cinema films. Mr. Boughey has written a little book which gives a popular account of the industry from start to finish, and which makes clear, with the aid of a large number of illustrations, the many different types of appliance, from camera to projector, which are concerned in the exhibitions in the cinema theatres. He steers a reasonable midway course between too highly technical details and that kind of loose description which does not in fact convey anything to the reader. Statistics crop up constantly in his pages. It is a common trait of the cinematograph industry to measure success in thousands of feet or hundreds of thousands of dollars, and that is perhaps inevitable in an industry which has very quickly accumulated great wealth by marketing an output, much of which is of very mediocre quality. Nevertheless, it is interesting to note the estimate of the number of cinema theatres in the world, namely, about 87,000, requiring 1,500 million feet of film per week for performances. In the United Kingdom it is estimated that over 200,000 people are employed in the cinematograph industry, as compared with just over 1,000 in the period 1904-5. Probably few industries can exhibit such an extraordinarily rapid development. Mr. Boughey's eleven chapters provide a clear bird's-eye view of it as regards both the manufacturing and commercial sides.

Radiographic Technique. By T. Thorne Baker. London: Constable. 15s. net.

BETWEEN the doctors who know little about electricity and next to nothing about photography, and the electricians who talk none too intelligibly on electrical matters, the literature of X-ray work has fared rather badly from the standpoint of the growing number of people who wish to make themselves proficient in the technique of producing creditable X-ray photographs. During the last few years there have been some notably good additions to text books on radiography, but perhaps too comprehensive for the purposes of the radiographic operator. By confining his field within the scope of the facts which the user of an X-ray installation requires to know, Mr. Thorne Baker has consulted the needs of the practical radiographer. The first chapter of his volume brings within a small compass the description of the average X-ray outfit; the remaining part of the book is devoted to what may be termed X-ray technique, namely, the exposure and development of plates, the use of intensifier screens, visual examination with a screen and the photographic methods of developing and printing. Although these may seem superfluous to readers of the present notice, they are, in fact, of the greatest necessity to many operators in charge of X-ray installations, for the want of knowledge of photographic methods exhibited by many of these latter is a source of constant astonishment to those who would naturally assume a fairly close acquaintance with ordinary photographic practice. In later chapters Mr. Thorne Baker deals with commercial and industrial applications of X-rays, and his text book includes also working photographic formulæ and recommendations for protection of operators from the rays and from high-tension shock.

A Dictionary of Chemical Terms. By James F. Couch. New York: D. Van Nostrand Co. 2 dollars 50

MODERN chemical language has now such a specialised vocabulary of its own that the author of this compilation has performed a useful task in providing the means of quickly ascertaining the significance of the terms and contractions in current use by chemists. The volume is for the professional chemist or student, but a large proportion of the definitions which are included in it may be considered to be reasonably intelligible to those who are strangers among chemical literature and are trying to puzzle out the meaning of some chemical paper which is beyond their knowledge. Apparently Mr. Couch has deliberately restricted his field to pure chemistry; chemical technology or manufacture appears to be very slightly represented in it. And a fairly close inspection of his pages has disclosed to us only one photographic term, and that, one which we have never heard. On page 10 "Amasthenic" (= amacratic) is stated to be the name of a form of lens which focusses the actinic rays. If we may make any criticism of a work which we think has been most excellently conceived and carried out, it is that the terms of bio-chemistry get rather more than their due share in the dictionary. Perhaps that has resulted from an unconscious bias on the part of the author, who is chemist in the Bureau of Animal Industry of the United States Department of Agriculture. But we think the compilation would benefit by more ample consideration of, for example, the terms for physical phenomena and units with which chemists have to deal. The entry under "Density" might refer to the optical significance of this term, and in the paragraph on "Calorie," which evidently aims at being comprehensive, there might, with advantage, be a mention of the gross and net calorific values, according to inclusion or otherwise of the latent heat of steam, much used in the calorific measurements of fuels. However, when so much has been done with evident care and capacity, it is perhaps an injustice to the book to single out such instances as the above. We must express our opinion that the volume is one which every chemist and student of chemistry will constantly find of the utmost usefulness.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, JUNE 12.

South London Phot. Soc. Excursion to Dorking.
Hammersmith (Hampshire House) P.S. Outing to Windsor.

TUESDAY, JUNE 14.

Scottish C.W.S.C.C. (Glasgow). "Home Portraiture."
Hackney Phot. Soc. "Beginners' Difficulties."
Manchester Amateur Phot. Soc. "Methods of Producing Diffusion as Applied to Portraiture and Landscape." Francis Fielding.

THURSDAY, JUNE 16.

Glasgow and West of Scotland. Excursion to Cadder.

FRIDAY, JUNE 17.

R.P.S. Pictorial Group. "Foregrounds." J. C. Warburg.

SATURDAY, JUNE 18.

Scottish C.W.S.S. (Glasgow). Outing to Blanefield.
Bradford Phot. Soc. Excursion to York.
Manchester Amateur Phot. Soc. Ramble to Prestbury Village.

ROYAL PHOTOGRAPHIC SOCIETY.

At the meeting of the Pictorial Group of the Royal Photographic Society on Friday evening last, Mr. Marcus Adams opened a discussion on "The Eyes in Portraiture." The subject was found so exciting and varied that its further consideration was adjourned to a later date when it was understood such problems would be dealt with as the comparative value of the panchromatic plate in the rendering of the eyes.

Mr. Adams's remarks were mainly a criticism of painters, particularly the exhibitors at this year's Academy, who, he said, had lost, or had never possessed, the faculty of representing the soul in these features. In some of the portraits at present at Burlington House Mr. Adams thought that compasses must have been used to draw the face. As a result of a recent study of eyes, which had occasionally caused him some embarrassing moments, Mr. Adams brought forward certain dicta. Eyes were as various in shape and colour and expression as the flowers of the field. They betrayed character to an astonishing degree. Although silent, they had a good habit of telling the truth even when their owner attempted to lie. Intuitively through his eyes a person often sympathetically denoted his heart felt feelings when words were too harsh or crude for delicate emotion. Eyes, through the mind, had the power to hypnotise or capture another. Although actually the eyeball was always round, the setting of these orbs within it was very different, and it was the relative position of the pupil which gave expression. The size of the pupil was governed by the amount of light shining in, and the question for the portraitist was as to which size of pupil was most attractive.

Finally, the creases around the eyes were of immense value in portraiture, although often obliterated by an ignorant retoucher. The painter, said Mr. Adams, had everything in his favour, while the photographer was hampered by a crude mechanical process, which gave him only shape, tone values, and light and shade. Yet the photographer excelled the painter in the delineation of the eyes, and he believed that the sculptor, who had more difficulties than either, excelled both; he instanced particularly Rodin. One piece of sculpture in the Academy, the subject being the Prime Minister was specially worthy of study from this point of view.

Mr. C. P. Crowther, who was in the chair, said that it was his observation that the eye contracted very considerably under the illumination of the half-watt lamp of 3,000 c.p., and in order to avoid such excessive contraction he followed Mr. Luboshez's plan of asking sitters to look on the ground or to close the eyes for a little time before he exposed. He also mentioned that in Japan until recently it was the invariable custom to cut out the high-light in the eye. People could not tolerate an eye which had a little white speck in it, with the result that Japanese portraits were so commonly lifeless and glassy.

Mr. A. C. Banfield found it necessary in taking head and shoulders with certain portrait lenses to get at least eight feet away from the subject, in order to avoid actual squint. With regard to the most appropriate size of pupil, he was of opinion, to express it in terms of photographic optics, that if the full aperture were taken as *f*/4.5, the best effect was obtained by letting the pupil close down to the equivalent of about *f*/8. He agreed with the unpleasing effect of the pin-point pupil.

Mr. W. B. Ferguson had observed that the contraction of the pupil in the case of strong lights depended on the actual intensity of the light seen, and not on the total amount of the light. The pupil of the eye under diffused light was much larger than under concentrated light, although the total illumination in each case seemed about the same.

Among other speakers, Dr. G. H. Rodman thought that the practice of looking on the ground was really carried out by Mr. Luboshez, not with the object of securing a larger pupil, but to avoid the picture stare. Mr. T. H. B. Scott was eloquent as to the value of the delineation of the "countryside" all round the eyeball, and Mr. Bertram Cox thought that in addition to the contraction of the pupil a good deal depended on the contraction of the eyelids over the eyeball in getting the maximum of expression. Miss Olive Edis appeared as an advocate of daylight for effective rendering of the eyes. She did not believe that "old Sol" was beaten by an arc lamp. So far as the value of snapshot expressions went, she had got more natural expressions with long exposures—best of all when giving two or three minutes' exposure with the Autochrome plate. Other ladies who took part in the discussion deplored the common habit on the part of sitters to look up, which gave an exaggerated expression in a photograph, and also asked what should be done when the two eyes were looking in different directions.

Mr. Adams said that mothers often asked him to take children looking up, and though he did it, he knew it would be a failure. He was doubtful of Mr. Crowther's plan of looking down or closing the eyes just before exposure in order to prevent excessive contraction of the pupil, for the contraction was immediate, and would occur before exposure could be completed. Two eyes which looked in different directions were, especially in the case of children, difficult to deal with. The thing to do was first to get one eye fixed, and then gradually attract the other by means of something held in the hand until an approximately harmonious relation was secured; he added that a person who wore glasses should be portrayed as wearing them, because they were part of his personality. To return to the Academy—which was a sore point with Mr. Adams—he mentioned some of the pictures in which the delineation of the eyes was far from being successful—perhaps it would be cruel to name them in print—and added that he could not find a single example of the old triangular wedge of high-light in the eye; the shape of the high-light was either square or oblong or a band right across the pupil.

It was promised that when the discussion is resumed the case of the eye which follows the observer in every direction from which he may look at the picture will be explored to its sinister depths.

CROYDON CAMERA CLUB.

A print display last week concluded a highly successful session, the informal one, preferred by many, now beginning. The president, Mr. John Keane, and the honorary secretary, Mr. J. M. Sellors, despite sparo time being at a premium with both, still find time to run the club between them, and the trusty councillors, rarely called to conclave, bask in that sweet content which in these up-to-date times is ever derived from the knowledge of work escaped.

In order to persuade the new recruits to contribute, Mr. Sellors had laid stress on the fact that the print display was not intended to be an "exhibition." Paradoxically, the print display avoided making an exhibition of itself by forming a very excellent one, the best on the walls for years, a scientific section, due to Mr. Hibbert, adding materially to the interest.

In the absence of a detailed review it would be unjust to particularise, but an exception can be made in the case of Mr. Purkis, whose pictorial aspirations had hitherto been unsuspected. His one little "ewe-lamb" depicted a mendicant armed with a most horrible squint, surrounded by a countenance apparently ravaged by every known form of repulsive skin disease. Doubtless due to circumstances beyond control, something had played havoc with the photographic part of the picture, and undisguised and heavy handwork put a finishing touch to a thing the like of which has never been seen before, and it is hoped never will be seen again.

In honour of Derby Day a brass band stationed below played Old English airs in style, which if it had been a trifle nearer would have secured liquid refreshment from above. Criticism of the pictures, and many tributes to the secretary for the past fixture list terminated the proceedings.

Commercial & Legal Intelligence.

NEW COMPANIES.

F. Darton and Co., Ltd.—This private company was registered on May 27, with a capital of £1,000 in £1 shares. Objects: To take over the business of a manufacturing optician and scientific instrument maker carried on by F. A. Darton at 142, St. John Street, Clerkenwell, E.C., as "F. Darton and Co." The first directors are: F. A. Darton, Clare Lodge, Snakes Lane, Woodford; O. Darton, Ivyhurst, Reigate. Registered office: 142, St. John Street, Clerkenwell, E.C.1.

Stanley Pearce, Ltd.—This private company was registered on May 27, with a capital of £200 in £1 shares. Objects: To take over the business of manufacturing optician and scientific instrument maker carried on at 161, Wardour Street, Soho, W., as "Stanley Pearce." The subscribers (each with one share) are: S. Mitchell, 73, Burford Gardens, Palmer's Green, N.13, accountant; L. Bull, 38, Edith Road, West Kensington, W.14, accountant. The first directors are not named. Registered office: 161, Wardour Street, Soho, W.

Bedesco, Ltd.—This private company was registered on June 1 with a capital of £2,000 in £1 shares (500 pref.). Objects: To carry on the business of manufacturers of camera holders, stands and all kinds of photographic accessories, etc. The subscribers (each with one ordinary share) are: Brig.-Gen. H. B. Shackleton, C.B., C.M.G., 7, Park Place, St. James's, S.W.1; W. C. Devereux, 4, Oxford Street, W., engineer. The first directors are: Brig.-Gen. H. B. Shackleton, C.B., C.M.G., W. C. Devereux, and R. R. Bishop. Qualification: £50. Remuneration as fixed by the company. Secretary: W. C. Devereux. Registered office: 35, Bucklersbury, E.C.4.

Pearl Films, Ltd.—This private company was registered on June 2 with a capital of £1,000 in £1 shares. Objects: To carry on the business of agents for and dealers in films, photographic, negatives and positives, photo-plays, scenarios, photographic instruments, material and products, etc. The subscribers (each with one share) are:—E. G. Tindsell, 40, Datchet Road, Catford, S.E., clerk; S. E. Collings, 118b, Mallinson Road, S.W.11, clerk; Miss E. Josephs, 196, Willesden Lane, N.W.2; B. W. Gould, 18, Cicely

Road, Rye Lane, Peckham, S.E., clerk. The subscribers are to appoint the first directors. No qualification required. Remuneration as fixed by company. Secretary: H. A. Mabbott. Registered office: 86 and 88, Wardour Street, W.

News and Notes.

THE RAJAR COMPANY'S "Trade Notes" for June deal with a new concentrated one-solution developer the company have just introduced.

MR. F. A. SWAINE, of 146, New Bond Street, London, W.1, had the honour of photographing H.I.H. the Crown Prince of Japan at a private sitting at the Japanese Embassy on May 28.

BALKAN PHOTOGRAPHS.—The Balkan News Photo Service has been formed to supply foreign papers, magazines, etc., with photographs illustrating current events in the Balkans. The address of the Service is Sdraveta Str 30 Podouene, Sofia, Bulgaria, and correspondence may be in English.

GRIFFIN'S NEW LISTS.—Messrs. John J. Griffin and Sons, Ltd. Kingsway, W.C.2, have issued a new abridged list of thirty-two pages describing their cameras and photographic sundries also "Pointers for Professionals," an illustrated leaflet detailing studio furniture and other things of particular interest to professional workers.

THE MOUNT EVEREST EXPEDITION.—Our readers will be interested to learn that Messrs. J. H. Dallmeyer, Ltd., of Carlton House, Regent Street, Piccadilly Circus, S.W.1, were recently commissioned by the Royal Geographical Society to supply photographic apparatus for the Mount Everest Expedition, which is being undertaken by the Royal Geographical Society and the Alpine Club.

THE R.P.S. FELLOWSHIP.—We learn from the current issue of the Royal Photographic Society's "Journal" that there were twenty-two applications for the Fellowship before the last Council meeting and that only six were elected, namely: Arthur C. Banfield, Archer Clarke, Joseph Goodman, Geoffrey I. Higson, W. Harold House, and Herbert Lambert. Sixteen rejections must surely be a record.

AN INSIDE OUTING.—The members of the South Suburban Photographic Society have arranged an "outing" under the leadership of Mr. Percy B. Dannatt, A.R.I.B.A., to one of the old city churches, the whole afternoon to be devoted to interior work. We understand that the members are particularly interested in the problem of halation and development, and that efforts will be made to settle the question, the windows of the church selected being particularly bad ones to photograph.

CONTINENTAL PENCILS.—"Owing to the low exchange there has been such an extraordinary amount of foreign orders that 75 per cent. of the output went abroad." This significant sentence (writes a correspondent) is from the annual report of the Faber Pencil Company, who include retouching pencils among their manufactures. Last year the company made a gross profit of 4,300,000 marks, from which, after writing off over two millions taxation and for other purposes, a dividend of 5 per cent. was paid compared with 10 the previous year.

PLANS TO PROTECT X RAY WORKERS.—Active steps are being taken with a view of protecting X ray workers in their dangerous occupation. A committee was formed a few days ago as the result of a meeting at the Royal Society of Medicine, to take stock of the present position of the X ray worker, and consider means for his protection. Radiological societies and hospitals, and a number of the principal institutes in London sent representatives, and we understand that a committee of ten was formed, with one of the leading consulting physicists at its head. A small sub-committee was appointed to draw up a scheme for future investigation.

FERROTYPE MATERIALS.—The well-known firm of Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.2, which have for many years made a specialty of ferrotype cameras and materials, send us particulars of many things required for this popular branch of photography. Chief among the cameras are the "Aptos" and the "Shell," the former taking 2½ in. × 1¾-in. plates, and the latter 1-in. circular "buttons"; there are also the "Mandel" cameras, for "while you wait" postcards and buttons. A good stock of plates and postcards, stickyback mounts, frames, etc., required for working this branch of photography, is held by the firm, and we understand that supplies, once rather scarce, are now very plentiful.

AUSTRALIAN WAR PHOTOGRAPHS.—It is stated in the "Australasian Photo-Review" that in her collection of official battle photographs, Australia possesses a pictorial record of the war which equals that acquired by any of the other nations who participated in the conflict. Some idea of the comprehensive nature of the collection will be gained when it is stated that the number of negatives held by the Australian War Museum totals 20,000, in which are represented battle scenes taken during the fighting in every campaign in which the A.I.F. participated, views of devastated towns and villages in France and Belgium, photographs of training camps in England and elsewhere, and posed group photographs of nearly every A.I.F. unit. These photographs were taken on behalf of the Commonwealth Government during the war by official photographers, who included such men as Captains G. H. Wilkins, Frank Hurley, and Lieut. G. H. Baldwin. The Australian War Museum Committee has now completed arrangements for their sale throughout Australia, and any profit resulting from the sale will be devoted to memorial funds. Whole-plate sepia-toned bromides and coloured enlargements are offered.

GETTING THE "ATMOSPHERE."—A writer in the "Daily Chronicle" has been describing the work done in a film-producing studio, and a part of his account is of particular interest as it gives the film producer's method of getting the right "atmosphere." A picture of an infirmary is being taken, but the "look" on the faces of the nurses and others does not please the producer. "He walks away" (says the writer), "thinking, to the end of the studio and back. Suddenly, he says, 'Disinfectant please. I want some disinfectant thrown down here.'" Presently there is the sharp acrid reek of disinfectant in the studio. 'Good,' he says. He calls out, the girl comes in at the door of the ward. 'Good.' "shoot" that,' says the producer to the man at the camera. And the effect of that small dash of disinfectant is amazing. The emotions one saw in the faces are real. One can see like a blow the reaction that the impact of that sharp pervasive smell has on the actors as they come into the 'ward.' That little touch of realism has keyed the whole business up into an astonishing naturalness. The producer tells you that if one is to recreate real life, one must reproduce the conditions of real life as exactly as possible."

WOMEN PHOTOGRAPHERS

To the Editors.

GENTLEMEN,—Had those of your correspondents who have thought fit to criticise woman's work in photography been good debaters they would not have shown any spleen even had they possessed it.

It is ridiculous for "Onlooker" to say that "woman photographers are merely a passing fad of a fickle populace," and he would have your readers believe that we women operators are a modern invention, if not a product of the war, which you know is wrong. There have been women photographers for generations, and I remember as a child—now, alas! thirty-five years ago, and I am not afraid to say it—being photographed by a Miss Pugh, the daughter of Mr. W. Pugh, one of the pioneers of photography in East Anglia. Miss Pugh assisted her aged father, and I thought it very curious being photographed by a lady, and I did not feel very comfortable about it until my parents told me that ladies were quite as good as men with the camera, which proved in my

particular case to be true, for I never had a better portrait of myself.

Some time afterwards my father started a studio, he having always been interested in photography, and one of his treasures was a printed card of "Mottoes for Photographers." These mottoes—there were seven of them—were put together by Mr. O. G. Rejlander, and I always had the idea, as my father had, too, that Rejlander had women photgraphers in mind when he coined the first motto, viz., To an operator: "She who hesitates is lost." Otherwise why "she"? I cannot now remember all the mottoes, but those I do remember are: To a Printer: "Make hay while the sun shines." To a Toner: "Let not thy left hand know what thy right hand is doing." To a Spotter: "Keep within bounds," and to a Mounter: "Act on the square."

If your captious correspondents knew anything of the history of photography they would be acquainted with the fact that lady photographers—both amateur and professional—existed long before the war, and one day I hope to compile a list of what lady workers have done, such workers as Mrs. Francis Clarke, who twenty years ago won many medals, Mrs. H. Snowden Ward, Mrs. Cameron, Mrs. Welford, Miss Tomlinson, and many dozens of later workers whose names are household words to-day. There are also many lady workers whose names are not known, and only last summer on the beach of Bournemouth I watched a rather elderly lady doing really good professional work, and she was "old established." too, a fact, "Onlooker" may be surprised to hear.

Thanks to developing tanks and other modern conveniences photography is not the messy job it was in my father's time, and its simplicity to-day is an inducement for any lady to take it up.—Yours faithfully, ANNA STIGMAT.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

L. W.—We made inquiries some time ago and learnt that there are no restrictions whatever as regards photography in either France or Belgium.

G. B. A.—It is too early to say whether D.50 is free from any action on the skin, but we have learnt from Mr. Gear, who has been using it for some months, that he has not found any action of this kind.

W. J.—The microphotographs are, we believe, made exclusively in France, and we do not think that the magnifying glasses can be obtained here. The miniature photographs are made by the wet collodion process, which you would first have to master.

E. D.—The lens appears to be an old half-plate Instantograph lens, and the number (1887) badly scratched upon it is, in all probability, the date, while the initials C.W., also scratched, may be those of a one-time owner of it. The F numbers of the five stops are 14, 19, 23, 32, and 50, the US numbers of which may be said to be 12, 22, 33, 64, and 156 respectively.

T. P. W.—The ellipsoid system is quite a good one so long as you have a nice thin negative, but as the light is not very powerful, and as also it is further reduced by reflection, exposures are apt to be unduly long if the negative is at all dense; and also it is not possible to use some of the slower development papers which yield the best results as enlargements.

H. E. C.—We are inclined to think that the failure to get the right kind of grain is more likely to be due to variations in the quality of the benzole. As regards this, we advise obtaining the purest benzene. The different quality of the deposit, apart from grain, is no doubt caused by variations in the quality of the gums, but that is a rather difficult matter to ascertain, because these gums are very complicated substances chemically.

F. L.—The Cellerier-Parkes colour process (introduced about 1886) was a modification of the crystoleum process. A carbon transparency was developed upon a waxed sheet of glass, and on a sheet of paper was made a coloured sketch of the subject. The two—carbon transparency and sketch—were united, and the sketch, with the adhering carbon image, when dry, stripped from the glass. The results were said to be pretty enough, but to lack brightness.

L. D. S.—We must say that we know nothing about the business of photography on board ship. Do you suggest that merchant vessels carry a photographer? No doubt the large liners may do so, although we have not heard that they do, but we feel sure that such is not the case in the case of smaller vessels. Of course, a great deal of photography is done "on their own" by men in the Navy, who use their leisure time and opportunities profitably in this way. We may be ignorant of the existence of this business, but our opinion is that there are no opportunities such as you suggest.

P. R. C.—(1) It is difficult to say from the particulars you give what is the cause of the markings on the film. It appears to arise from the wash water in some way. Possibly your wash water is hard (chalky), and that would tend to cause such markings, particularly if any of the films were treated in an alum bath, or an alum fixing bath. If you constantly get the defect, we should advise giving the films a soak in a few changes of citric-acid solution after they have had, say, 20 minutes' washing, and, finally, a rinse in distilled water. This, perhaps, would show what is the most likely cause. (2) Mr. Stine's book on the Aerograph is not on sale in this country, but is published in the United States by the Abel Publishing Co., Caxton Building, Cleveland, Ohio.

M. T. B.—We cannot say, but the following cements for porcelain and metals, given in a recent issue of the "Scientific American Monthly," may be of service to you:—The first is composed of ground fluor spar, finely-powdered glass, and sodium silicate, commonly called water glass. The old standby, litharge, made into a paste with glycerine, is the second on the list. Another suggestion is a thick glue mixed with one-half part of boiled linseed oil. Another is zinc oxide, calcined magnesia, and sodium silicate in equal parts. This mixture should be dried slowly. Chalk or percipitated calcium carbonate and powdered zinc mixed in equal parts with sodium silicate is another formula. The final is 20 parts plaster of Paris, 50 parts of fine ground flint, and 30 of zinc oxide. This mixture is made into a thick paste with sodium silicate.

SUMMARY.

MM. Lumière and Seyewetz contribute an important article dealing with their investigations on the subject of desensitisers by dye stuffs. The matter is discussed from both the theoretical and practical standpoints, and the conclusion arrived at, that for all-round work the dye originally suggested by Dr. Luppo-Cramer (phenosafranine) is the most efficient. (P. 351.)

In the second chapter on the H and D. doctrine, the so-called Law of Constant Density Ratios is explained as a preliminary to the exposition of the part played by exposure in the making of a negative which is a correct, but inverse, reproduction of the subject. This involves the meaning of the characteristic curve of a plate, and leads to the definition of the latitude of a plate and of latitude in exposure. (P. 354.)

A new method of simultaneous developing and fixing; a collection of 1,800 Autochromes of all sizes, from 7 × 5 ins. to 16 × 7 ins., made for advertisement purposes; stereoscopic projection, and several other matters of interest, are dealt with by M. L. P. Clerc in his "Paris Notes." (P. 359.)

With the constantly greater use made of enlargements in comparison with contact prints, it seems inevitable that the condenser enlarging lantern should give place to an enlarging apparatus providing completely diffused or scattered illumination of the negative and, for the sake of greater convenience and expedition in use, built upon a vertical plan. (P. 350.)

Flatness of the image in tank developed negatives during the hot weather is often the result of using the developer too warm, and it is sometimes advisable to cool the solution. (P. 350.)

It was stated at the Croydon Camera Club that the too blue hue which the greens occasionally require when a Paget screen-plate is used may be corrected by dyeing the positive a pale yellow, while in the case of a too yellow slide, a blue dye may effect a cure. (P. 361.)

A prime condition of permanence in prints is their greatest possible freedom from moisture. From this standpoint the recommendation sometimes made to use a final glycerine bath, in order to prevent curling of double-weight papers, is open to serious objection. (P. 349.)

In a note on the unnatural cloud effects often printed into landscapes, it is pointed out that in many cases a sky of suitable tonal quality, though destitute of clouds, is more in accordance with truth to nature. (P. 350.)

A collection of the early photographic apparatus used by Fox Talbot with some of his experiments will be shown to members of the Photographic Convention when they visit Lacock Abbey on July 8 next. (P. 363.)

EX-CATHEDRA.

Glycerine and Fading. With the increasing use of double-weight bromide papers there has been a temptation to revive the practice of giving a weak glycerine bath to prevent curling. In these circumstances it may be useful to call attention to the danger of inducing fading in bromide prints by keeping them in a damp condition. Bromide prints in our possession made nearly forty years ago are now in quite good condition because they have been kept in a perfectly dry place, while others, made only two or three years and kept on the dark-room shelves, where the atmosphere is always damp, have faded to a sickly yellow. A large collection of unmounted, plate-marked prints which had been treated with glycerine to ensure flatness faded almost to invisibility in a few years. If a demonstration of the hygroscopic qualities of gelatine be needed, we have only to observe the surface of a tray of hectograph composition, which is composed of gelatine and glycerine which has been left uncovered for twenty-four hours in damp weather. The surface is found to be covered with globules of water absorbed from the atmosphere. In a lesser degree this is what happens to the glycerine print, the dampness of which facilitates the action of the sulphurous vapours found in the atmosphere of all cities.

* * *

Fine Art Essentials. That the work of the portrait photographer should be based at the very least on a lively appreciation of what is fine art, is a dictum which every studious professional portraitist at once admits, while in the same breath lamenting that art entered in very small measure into the training which he or she received. Unfortunately, the opportunities, such as they are, for students to acquire a living knowledge of art principles, present themselves only to those undertaking a systematic course of training in the technique of one or other of the manual graphic arts, such as painting and drawing; and even to them the good fortune does not invariably come of having a teacher able to lead them in the different, though cognate, paths of art and technique. Thus, in photography especially, it happens that training in art is often a work of self-education undertaken after a certain technical competency has been achieved. It is, therefore, in accordance with the realities of his situation that the ambitious portrait photographer should seek aid in his own artistic development wherever he can find it; and on that account we cannot sufficiently emphasise the value of the series of lessons on "The Appreciation of the Fine Arts," which is an outcome of the more general course on principles of æsthetics, devised and arranged by Mr. F. C. Tilney and directed by him from 28, John Street, Bedford Row, London, W.C.2. After having perused those lessons, as they are issued to participants in the course, we are bound to recommend them warmly to those wishing to see things through an artist's eyes. And

it is this gift of perception which more than any other is needed to redeem photographic portraiture from the lack of character with which so largely it may be fairly charged. It is obvious that in the absence of a correct or sharp recognition of what is good in art, there cannot be the progress in portraiture which, technically, is within the reach of photographers. This course of lessons deserves well of photographers as a whole for the means it provides for stimulating their thoughts and methods.

* * *

Under-Exposed Negatives. Although it is generally recommended to destroy apparently hopelessly under-exposed negatives, it is sometimes necessary to take any amount of trouble to obtain a passable result from such plates or films. A plan which has been worked with success is to treat the negative as an opaque and not a transparent object; that is to say, to back it with white paper in an ordinary printing frame and to copy it in the camera, using a contrasty bromide paper instead of a plate. A process plate may be used, if desired, and will, of course, give a positive transparency from which a negative may be made by contact. An alternative method is to bleach the negative with mercuric chloride, back it with black velvet, and proceed as for an ordinary glass positive. In either case the negative must have the shadows cleared with a suitable reducer or the result will be too flat. Still another method is to fix the negative in a frame or clip and place a dead black background at a considerable distance behind it, then to illuminate the film obliquely by *transmitted* light. This method sometimes gives remarkable results from negatives which are too thin and flat to be amenable to any other procedure.

* * *

Cooling the Tank. During very hot weather various troubles, such as flatness of the image, softening of the film and over-development are likely to arise if the temperature of the solution in the developing tank is allowed to rise much above 70 deg. Fahr. It is, however, quite easy to cool the solution without removing it from its receptacle by sinking in it a bottle filled with broken ice and water, and leaving it until the necessary reduction of temperature is made. Care must be taken to keep the solution stirred, either with a stick or with the bottle itself. so that the cooling is not localised, and a thermometer should, of course, always be used The colder mixture of ice and salt has been recommended, but if this be used it is necessary that none of the solution escapes into the tank. Conversely, the developer may be warmed in winter by using hot water in the bottle instead of cold, but in this case it is necessary to use well-tempered glass or, better, stoneware, a ginger beer bottle answering very well. Metal cans or bottles may be used, but are liable to contaminate the solution unless quite free from rust or corrosion.

* * *

Clouds as they are. Those who visit modern photographic exhibitions with a view to an intelligent study of the work on view cannot do so without being forcibly struck with a lack of observation of effects seen in Nature on the part of prominent photographers. In this connection we refer to the introduction of clouds into landscapes, which is one of the points at which many workers go wrong. When introducing clouds into a photograph it is not only important that the clouds should be in keeping with the landscape portion of the picture with regard to lighting, but the scale of the individual clouds should also be in harmony. In many pictorial photographs that we have seen in the past this point has been altogether neglected; in one instance a single large cumulus cloud occupied the whole sky portion of the picture, while the rest of the composition included a very large area of distant landscape. Such an effect in Nature would never have been seen, and whatever value the picture might have gained from the Art point of view is therefore discounted. A fact that does not seem to strike many workers is that a sky need not necessarily contain clouds. Not that the sky portion of a print should be an expanse of white paper, but a sky of luminous tonal quality is often far more expressive of truth than is the over-assertive sky often introduced by photographers. Observation of Nature will readily prove that clouds do not pile themselves up in overpowering masses over a sunny landscape.

THE PASSING OF THE ENLARGING LANTERN.

PERHAPS the piece of photographic apparatus which has remained longest without basic alteration within the memory of the younger generation of photographers is the condenser lantern sold for the making of enlargements. We are speaking now of the optical principle of the appliance, not of its mechanical details. As regards the latter, manufacturers have certainly been unremitting in introducing various movements and fitments which contribute to the more convenient and expeditious employment of the apparatus. We have had rack and pinion adjustments of the negative in its stage in all directions, masking devices and the incorporation with the negative carrier of a line transparency for facility of focussing, to mention only a few of the ingenious contributions by those responsible for the design of enlarging lanterns. Nevertheless, it may well be thought that there is the occasion for a radical reconstruction of the type itself; and we believe that there are already signs that the somewhat cumbrous condenser lantern has had its day. We think that manufacturers would not greatly regret its departure, for enlargers, of this type, as currently made, are heavy and bulky pieces of apparatus and, despite their undoubted merits for their work and the relatively low prices at which they are sold, are not the easiest things for which a large demand can be created. From the point of view of the user of them, who usually is an amateur worker, they suffer from the drawback of taking up a great deal of space when enlarging is being done and, further, require a degree of correct adjustment of the light which is more than can be expected of a large proportion of the pampered amateur workers of the present day.

Professionals, we believe, largely "rig up" their own enlarging apparatus, composing it from some old pattern of field camera, and often using daylight as the source of illumination. Inasmuch as most professional negatives carry a considerable amount of retouching, the condenser enlarger, by reason of its emphasis of retouching marks in the enlargement, is not the best for the purpose; and daylight, with its merit of excellent diffusion and despite its drawback of constantly varying strength, is found to be more suitable. At the present time we are witnessing the introduction of enlarging apparatus differing from the typical condenser enlarger in two respects: (1) the use of highly-diffused or scattered light from an artificial source, instead of light concentrated along an optical path by the condenser, and (2) a vertical instead of a horizontal type of construction. In both these respects the advantage to the user, whether amateur or professional, is manifest. The system of illuminating the negative by diffused light minimises the emphasis of retouching marks in the enlargement, and also cuts out

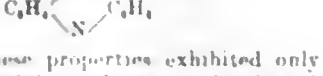
the necessity of making a suitable adjustment of the position of the light in correspondence with varying degree of enlargement. In this respect, therefore, the system serves, for different reasons, the needs of both amateur and professional. The diffusion of the artificial light, which can be gas or electric, may be done by reflection of the light from a matt white surface or by passage of the light through a scattering medium, such as opal; or, usually and most advantageously, by a combination of these two systems, the light or lights being contained in a box the inside of which is a matt white, whilst a screen of opal or ground glass is placed a short distance from the negative on the side towards the light. The diffusing screen thus receives the direct and reflected rays from the lamp, further diffusing or scattering the former in transmitting them to the negative.

As regards the build of the apparatus, again, both for amateur and professional purposes, the advantages of a vertical pattern are self-evident. The amateur must necessarily appreciate an enlarging apparatus which can stand ready for use and occupies very little floor space, whilst the professional has also occasion to value the more rapid operation of a vertical apparatus, which obviously could be made to produce enlargements almost as expeditiously as the present printing boxes produce prints. The name given to the vertical self-focussing enlarging apparatus by the Kodak Company, namely, "Projection Printer," does, in fact, foreshadow the possibilities—or we should say, practicabilities—of rendering enlarging as rapid a process as printing. We had some notes a few weeks ago on enlarging from this standpoint; and in returning to the topic, as we have done in the present article, we are seeking to show that the making of enlarging as universal a process as printing now is, depends upon a thorough revision of existing enlarging apparatus, and particularly the condenser enlarger. At present manufacturers have shown very little evidence in the shape of goods on the market of having taken this modern view of the enlarging process. There are plenty of opportunities for designers to show their ingenuity in designing new types of apparatus, which, we venture to think, will owe their success to their adoption of completely diffused artificial illumination and a vertical arrangement of their constituent parts.

EXPERIMENTS ON DESENSITISERS.

The discovery made by Luppo Cramer[1] of the remarkable desensitising action of the azo dye known as phenosafranine, and also of other dyes of the same class on ordinary and panchromatic plates, without affecting the latent image, has prompted us to study the possible relation between the desensitising property of the substance and its chemical constitution. The questions which we have endeavoured to answer are the following:—

(1) Are the properties of phenosafranine common to all the substances derived from the phenazine group,



of safranine, or are these properties exhibited only by substances which are derived from this group by the substitution of radicles analogous to those which give rise to phenosafranine?

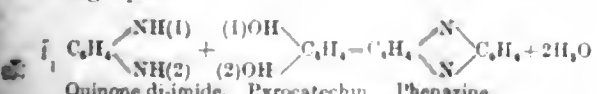
(2) Are the compounds containing the phenazine group the only organic substances having this desensitising property, or is the latter to be found among other coloured organic bodies or mineral compounds? Do desensitising substances act equally on ordinary and panchromatic plates?

(3) Is the desensitising quality a chemical, physical or physico-chemical one?

(4) Selection of desensitisers according to the purpose for which they are to be used.

Turning now to these four aspects of the subject, phenosafranine is a red dye belonging to the azo class, the phenazine group in which may be considered as derived from the substance, quinone di-imide,

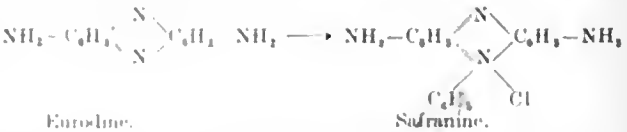
It may be assumed that phenazine is produced by the action of quinone di-imide on pyrocatechin according to the following equation:—



Quinone di-imide. Pyrocatechin. Phenazine.

(1) "Photographische Rundschau," 1921, p. 29.

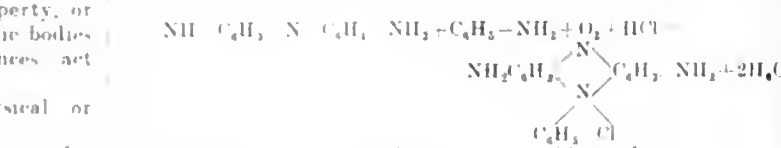
The introduction of two NH_2 groups yields a eurodine, and the further attachment of a phenyl group to the azo nitrogen of the eurodine gives rise to a safranine.



Eurodine. Safranine.

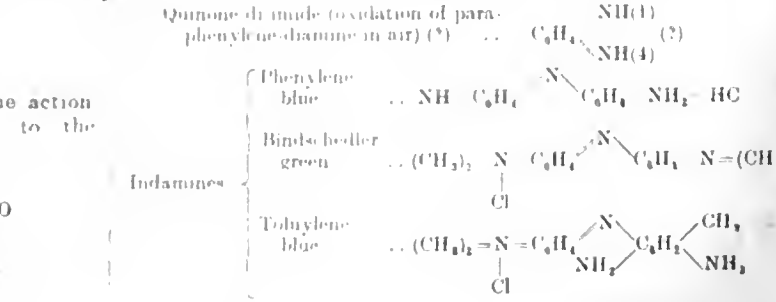
Phenosafranine is produced directly by oxidising a mixture of 1 molecule of para-phenylene-diamine and 2 molecules of aniline. This oxidation occurs in two stages, an indamine being first formed:—

Para-phenylene-diamine. Aniline. Indamine (blue dye).



Indamine. Aniline. Phenosafranine.

There is therefore an interest in studying the desensitising properties of the various intermediate compounds which precede the formation of phenosafranine. These are:—



Phenazine .. .. .. 
Eurodines { Toluylene red .. 
Neutral violet .. 
Desensitising Ordinary Plates.

The following method was used in studying the desensitising of ordinary plates:—

Plates of ultra speed (Lumière Violet Label) were placed, in the dark, for 2 minutes in a solution of the dye, ranging, according to the particular substances, from 1: 100 to 1: 2,000. Successive tests were made in order to find the minimum strength of dye solution which could be used for the production of the maximum desensitising effect.

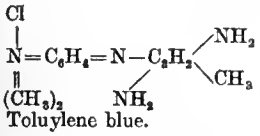
The plates were all exposed under identical conditions in the Chapman-Jones plate-tester, and, on removal from the desensitising solution, were developed at a distance of 1.5 metres from a candle, the light of which was reflected vertically on to the developing dish so as to illuminate the plate uniformly from above.

A normal diamidophenol developer was used for 4 minutes at a temperature from 60 to 64 deg. F., the plate being examined twice by transmitted light, first after 2 minutes and then after 3½ minutes.

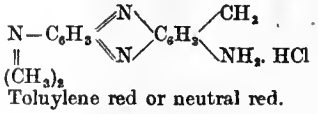
When the images thus developed showed only a slight fog, spectroscopic tests on panchromatic plates, developing in a bright yellow light, were made as described in a later portion of the present paper.

Among the substances already mentioned, aqueous solution of paraphenylene-diamine exerts a very slight desensitising action; the other substances, with the exception of toluylene red, are without action. Toluylene red (neutral red) gives results closely comparable with those of phenosafranine.

This dye is made by boiling in contact with the air the unstable indamine dye, toluylene blue, which results from the action of di-methyl-para-phenylene-diamine on meta-toluylene-diamine.



Toluylene blue.



Toluylene red or neutral red.

It thus appears necessary that the following two conditions should be fulfilled:—

(1) Presence of the phenazine group.

(2) Substitution of amido groups in the benzene nucleus.

Nevertheless, although these two conditions appear to be fulfilled in the case of neutral violet (which contains a CH_3 group less than neutral red), this dye does not possess the properties of neutral red. Possibly it has not the constitution which is commonly attributed to it.

Neutral red is a brownish-red dye of low brilliancy which has a feeble staining action on gelatine and washes out more easily than safranine. At the same time it enters into the gelatine film more slowly, so that it is necessary to bathe the plate for about 4 minutes in a 1 per thousand solution in order to impregnate the film with the solution.

Action of Different Safranines.

We have compared the desensitising properties of a considerable number of safranine dyes with those of phenosafranine. Some of the dyes which we have used are commercially obtainable; others have been prepared. The following are the colouring matters which have been examined.

Commercial Name. Scientific Name.	Formula (and Colour of Solution in Water).	Desensitising action compared with phenosafranine.
Dimethyl-phenosafranine.	 (Violet).	Slightly inferior
Tetra-methyl-phenosafranine.	 (Violet).	Slightly inferior.
Amethyst violet. Tetrethyl-phenosafranine.	 (Violet).	Similar.
Giroflé. Dimethyl-benzoxylyl-safranine.	 (Violet red).	Similar.
Ordinary safranine. Tolusafranine.	 (Cherry red).	Similar.
Safranine MN. Methyl-tolu-safranine.	 (Cherry red).	Similar.
Fast neutral violet D. Ethyl-dimethyl-etho-safranine.	 (Blue violet).	Slightly inferior.
Induline scarlet. Tolu-naphtho-etho-safranine.	 (Orange red).	Slightly inferior; discharge of colour difficult
Azocarmine X. Disulpho-phenyl-naphtho-benzo-safranine.	 (Slightly soluble to violet red).	Much inferior.
Indazine M. Dimethyl-amido-phenyl-dimethyl-benzo-safranine.	 (Blue violet).	Much inferior; attacks latent image.
Creso-safranine.	 (Cherry red).	Similar.
Apo-safranine. (hydro-chloride).	 (Violet red).	Much inferior.

Commercial Name. Scientific Name.	Formula (and Colour of Solution in Water).	Desensitising action compared with phenosafranine.
Homo-aposafranine.	 (Cherry red).	Much inferior.
Amidosafranone.	 (Red).	Much inferior.
Phenonaphthosafranine	 (Cherry red).	As phenosafranine.
Diazo derivative of phenosafranine.	 (Blue).	No action.
Indoine blue R. Diazo derivative of phenosafranine and β naphthol.	 (Violet blue-black).	No action.
Acetylphenosafranine.	 (Reddish yellow).	No action.
Safranone.	 (Red).	Much inferior.
Safranol.	 (Red).	No action.

The results obtained with dimethyl, tetramethyl and tetraethyl phenosafranine and with safranone and safranol have already been pointed out by Lüppo-Cramer and König ("Photographische Rundschau," 1921, p. 37).

In the foregoing table it is seen that the dyes of the safranine class which possess desensitising properties comparable with those of phenosafranine are:—

Dimethyl-phenosafranine.
Tetra-methyl-safranine.
Tolusafranine (ordinary safranine).
Methyl-tolu-safranine (Safranine MN).
Dimethyl-benzoxylyl-safranine (Giroflé).
Tetra-ethyl-phenosafranine (Amethyst violet).
Cresosafranine.
Naphthophenosafranine.
Ethyl-dimethyl-etho-safranine (Fast neutral violet D).

None of the above possesses any appreciable advantage in practical use over phenosafranine, with the exception of cresosafranine, which is distinctly more easy to wash out of the gelatine film than phenosafranine.

It will be noticed that safranines which have lost anamino group, *e.g.*, the aposafranines, and those, *e.g.*, safranones, in which this group is replaced by oxygen, have the desensitising property much less marked. If the two amino groups are replaced by O and OH, as in safranol, the property is altogether destroyed.

Replacement of this NH_2 group by acetyl, its conversion into the diazo group or the formation of a diazo compound with a phenol, as in indoine blue R, destroys the desensitising property of the original phenosafranine. On the other hand, the substitution of a C_6H_5 group (attached to the azo nitrogen) by C_2H_5, as in fast neutral violet D, has no effect on this property.

Desensitising Action of Indulines.

The indulines are dyes closely analogous to the safranines. They may be regarded as aposafranine

 (phenosafranine from which an NH_2 group has been eliminated).

in which one or more hydrogen atoms of the benzene ring are replaced by the aniline residue, NHC_6H_5.

The desensitising action was tested of the following indulines, chosen among those which include 1, 2, or 3 aniline residues substituted in the benzene rings and having methyl or ethyl groups in the amido groups:—Fast blue 3R, soluble induline B, paraphenylene blue R, metaphenylene blue 2B, azine green, azine green S, Bale blue R, Milling blue, and Coupler blue.

The colour of the solutions ranged from violet blue to greenish blue, but none of these dyes showed any desensitising action.

Thiazines, Thiazones, Oxazines and Oxazones.

The thiazines and thiazones, as also the oxazines and oxazones, are regarded as derivatives of quinone imide. These dyes have a constitution approximating to that of the safranines, or rather the eurodines, one of the phenazine nitrogens being replaced—by sulphur in the thiazines and thiazones, and by oxygen in the oxazines and oxazones.

Thiazine.
Lauth violet .. 
Oxazine.
Nile blue 2B .. 
Oxazone.
Resorufine .. 
We have examined the action of the following dyes exhibiting substitution of various kinds and of colour ranging between blue and violet:—

Thiazines.—Gentian violet; methylene blue; thiocarmine R; toluidine blue.

Oxazines and Oxazones.—Capri blue; gallocyanine; Prune O; Meldola blue; Nile blue 2B; fluorescent blue.

None of these substances showed desensitising properties approaching those of phenosafranine.

These different classes of dye, although derived, as is phenosafranine, from quinone imide, thus appear to be destitute of useful desensitising action.

Desensitisers from Other Classes of Dyes.

We have investigated the action of a large number of dyes belonging to other classes than those derived from quinone imide. The only ones which showed any notable action are those included in the table on p. 354.

Names.	Formula (and Colour of Solution).	Desensitising action compared with phenosafranine.
Nitro compounds : Picric acid (tri-nitrophenol).	$C_6H_2(OH)(1)(NO_2)(2)(NO_2)(4)(NO_2)(6)$ (Yellow).	Strong action ; image not fogged.
Aurantia (ammonia salt of hexa-nitrodiphenylamine).	$(NO_2)_3-C_6H_2-N(NH_4)-C_6H_2(NO_2)_3$ (Reddish yellow).	Very strong action ; image not fogged.
Indian yellow (nitro derivative of orange IV.).	$SO_3H-C_6H_4-N=N-C_6H_4-NH-C_6H_4NO_2$ (Orange yellow).	Considerable action ; image slightly fogged.
Azo compounds: Chrysoidine (Diamidoazo-benzene hydrochloride).	$C_6H_5-N=N-C_6H_3(NH_2(1))(NH_2(3))\cdot HCl$ (Brownish yellow).	Strong action ; image not fogged.

The desensitising action of crysoidine has been pointed out by König and Lüppo-Cramer,[2] who, however, have not stated if this dye produces chromatic desensitising comparable to that of safranine.

In short, there appears to be no well defined relation between the constitution of the dyes and their desensitising properties, since, among the derivatives of quinone imide, only the safranines and one eurodine possess this property, whilst among very different dyes there are found isolated desensitisers, such as aurantia in the nitro derivatives, and chrysoidine among the azo dyes, the constitution of which is not closely related to that of the safranines. In the case of chrysoidine, if there are two NH_2 groups, these latter are in the meta position relatively to each other, and are not susceptible of yielding by oxidation in the air a quinone imide as they would if in the para or ortho position.

It is of interest to compare these results with those obtained in respect to colour sensitisers. As is well known, there are two classes of dyes, the cyanines and the phthaleins, most of the members of which are colour sensitisers, whilst, on the other hand, there are isolated examples of other classes of dyes, *e.g.*, rosaniline and azo dyes, which possess this property

A. and L. Lumière.
A. Seyewetz.

(To be concluded.)

(2) " Photographische Rundschau," 1921, p. 37.

THE H. AND D. DOCTRINE.

In the previous chapter we considered the condition which a negative requires to fulfil in order that it may be a theoretically perfect reproduction, but in inverse or negative light and shade, of a scene or object.

We saw that the condition is that the light-intensities *transmitted* by the various parts of the negative shall be inversely proportion to the light-intensities *reflected from* the corresponding parts of the subject.

We became familiar with the conception of opacity as an alternative form of describing transparency, opacity being simply the inverse or reciprocal of transparency.

Whence, in the theoretically perfect negative, the opacities of the various deposits are directly proportional to the light-intensities from the corresponding parts of the subject.

We then saw the relation of the relative quantities of actual stuff (density) forming the deposits to the opacities of the latter and found that this relation is that of an index or logarithm. The density is the logarithm of the opacity.

Thus it became evident that in a theoretically perfect negative the difference between two densities is equal to the difference between the logarithms of the exposures which produced them. The opacities are then proportional to the corresponding light-intensities from the subject.

We have now to see how this condition depends, in the first place, on the time during which the plate is exposed to the action of light. In doing that we shall become familiar with the method originated by Hurter and Driffield, namely of representing the effect of exposure of a plate by means of a so-called " characteristic curve."

II.—THE LAW AND LIMITS OF CORRECT EXPOSURE.

Exposure, Development and Density.

If a plate receives the same exposure over all its surface, *e.g.*, by exposing it to the light of a candle at a considerable distance, a uniform density is obtained on development. As every photographer knows, within certain limits, the density depends partly on the exposure, partly on the time of development, and partly on the plate. All these factors come into play in the making of a negative, and Hurter and Driffield at the outset of their investigations set themselves to discover the separate influences of exposure and development on the production of a negative true to the original. They did not succeed in this until they studied, not a single density produced by a single exposure, but a series of densities produced by a series of exposures; in other words, when they studied the ratios of densities to each other. The rule or law connecting a single exposure with a single density is a very complicated one and involves development, but, as Hurter and Driffield were the first to show, the rule connecting a series of exposures with a series of densities can be expressed in a very simple way, involving exposure only.

In studying this first step in the making of a negative, we are following the lines of photographic practice. Except as regards speed of printing, the absolute values of the opacities of a negative are immaterial; it is their relative values which determine the correctness of a negative. As every photographer knows, a negative which is of considerable opacity throughout its various gradations may give as good, *i.e.*, as true, a print as one which is thin. It will take longer to print; a practical drawback certainly, but not one which is opposed to correct reproduction.

Development and Density Ratios.

Before considering the relation of successive exposures to densities we must examine a property of development. If the same series of any exposures be given to several plates and the plates be developed for different times, it is found that though the actual densities are different in each plate, they

preserve the same ratio to one another as development proceeds. An example from Hurter and Driffield's paper of 1890 (Experiment 13) will make this clear.

Exposures	1	2	4	8
Densities D_1 (4 mins. development)	0.775	1.000	1.180	1.250
Ratio of Densities D_1	1.0	1.29	1.52	1.61
Densities D_2 (12 mins. development)	1.260	1.660	1.96	2.08
Ratio of Densities D_2	1.0	1.31	1.55	1.65
Ratio of $D_1 : D_2$	1.63	1.66	1.66	1.60

It will be seen that within the limits of experimental error of measurement, the densities by 4 minutes' development have the same relation to each other as those by 12 minutes' development, or, what is the same thing, each density by short development stands in the same proportion to the corresponding density obtained by longer development, as shown in the last line. This preservation of proportion is what Hurter and Driffield called the law of constant density-ratios. They maintained that it held good in the use of different developers, and even when bromide is added to the developer, and therefore they declared that the ratio of densities is unalterable by modifications of the developer or development.

It was this statement that aroused so much controversy when it was first made. This arose from various causes, which it may be well to recall, although the battle of the density-ratios is almost forgotten. In the first place photographers thought density-ratios meant opacity-ratios, which, as we shall see later on, are a measure of contrast and *are* altered by development. In the second place, Hurter and Driffield omitted to qualify their statement (that density-ratios once formed on exposure cannot be altered in development) by indicating that they meant:—Cannot be altered in a definite or controllable way, or so as to rectify the error caused by incorrect exposure. They admitted this omission in their paper of 1898 on "The Latent Image and its Development." In the meantime reams of print were filled in showing that under certain conditions and chiefly by means of modifications in the pyro-ammonia developer an improved result could be got from an under- or over-exposed negative, though not with any degree of certainty, not in a precalculable manner, and not to a degree which remedied errors of exposure so far as correct reproduction of the tones of a subject is concerned. Other reams were filled in proving that longer development increased the amounts of the differences between the densities, and thus the contrast, which of course was never denied, but on the contrary specifically shown, by Hurter and Driffield.

The Exposure-Density Relation.

So we are clear in understanding the law of constant density-ratios to mean that whatever densities are produced in a plate, first latent and then visibly by the developer, they remain *relatively* the same during a normal period of development. The individual densities are increased as development proceeds, but their ratio to each other is not altered. If the ratio is wrong at the start, it may be altered, but is not corrected, by "tinkering with the developer."

The question is: Under what conditions is it obtained right at the start? By correct exposure. Yes, but what is correct exposure in definite terms? For this we must retrace our steps and examine the experimental manner in which the relation of exposures to densities was investigated.

Densities and Increasing Exposures.

By giving a series of exposures (each the same multiple, say double, of the preceding) to different parts of the plate, and developing for any convenient time (length immaterial), Hurter and Driffield found that the lowest densities, produced by the smallest exposures, differed from each other by relatively small but gradually increasing amounts, and that at a certain point in the series of successively doubled exposures, this difference between each density and the preceding one reached a maximum and continued approximately at that maximum until a second turning point was reached at which the increase of density at each doubled exposure begins to fall off; and, finally, further doubled exposures produce actually less and less densit

These four phases in the growth of density, which follow eacl other as exposure is increased, can be recorded in various ways. We can set down in adjoining columns (1) the exposure, (2) the density, and (3) the addition to the density. Such a table shows the general nature of the progression of density, but not in a very striking way.

Plotting Density Against Exposure.

Another way is to represent the course of the growth of density by a line. We draw two lines at right-angles, meeting at a point, as shown in Fig. 5. On the horizontal line we can mark off from O distances proportional to the exposures, and on the vertical line distances proportional to the corresponding densities. On then drawing vertical lines through the points on the horizontal scale and horizontal lines through those on the vertical scale we get a series of intersections; and on joining these together by short, straight lines we get a line (which in some parts may be straight and in others curved) the shape of which indicates the rate at which density increases with exposure. This line rises very steeply at first, then less steeply, and becomes much flatter in the phase corresponding with the longer exposures. It may even slope downwards if the chart be made large enough to include the phase (reversal) during which density becomes less in actual amount with each successive doubling of exposure.

There are, however, two objections to plotting density against exposure in this way. One is that the range of the two values is very different. The densities which are measurable in a negative run from about .1 to 3.5, *i.e.*, a range of 1 to 35. But exposures required to produce such a range of densities may vary from 1 to about 8,000. Therefore, the exposure scale has to be enormously big in order to show slight differences of density. This objection may be overcome, though at great inconvenience.

The second objection cannot be overcome. It is that the portion of the line representing the second phase (of equal *addition* of density for each *multiple* of exposure) will always be curved. This arises from the fact that there is not a simple relation between the densities and the exposures which produce them; density-values corresponding with exposure-values progress according to a different rule from that of the latter. But this part of the line, as we shall see directly, is the most important part. It is the part which largely measures the quality of the plate. You can't readily tell where such a curve comes to an end, or how long it is, and so cannot compare the curves for different plates. For this reason the plotting of exposures against densities gives little useful information.

Logarithms and Log Exposures

But the *logarithms* of exposures progress according to the same (additive) rule as do the densities corresponding with them. The two are like quantities in this respect.

That this is *so* will be clear if we recollect the nature of a logarithm as briefly indicated in Chapter I. of this series of articles. A logarithm is an index (or an exponent as the mathematicians prefer to call it). The logarithm of a number, e.g., of A, is the number of times a certain base number must be multiplied by itself in order to produce A. Any base number may be chosen, 10 being commonly adopted. Thus, since $10 \times 10 = 10^2 = 100$, the log of 100 to base 10 is 2. Similarly, $\log 1{,}000 = 3$. On this system the logarithms of numbers from 0 to 999999 and over have been worked out and arranged in tables. As $\log 1 = 0$, the logarithms of numbers (i.e., decimal fractions) between 1 and 0 are minus quantities.

By way of example of the respective progression of numbers and their logarithms we may compare:—

Number	10	100	1,000	10,000
Log	1	2	3	4

While the numbers progress by multiple (of 10), their logs progress by addition (of 1). That is a characteristic property of logarithms, and, as we shall now see, is one reason for choosing log exposures instead of the exposure values themselves for plotting against densities.

B

Plotting Densities Against Log Exposures.

If, then, we plot densities against *logarithms* of exposures, and it is found that any part of the "curve" is a straight line, it is made evident that as exposures are increased by some multiple—that is, as the log exposures increase by the same amount at each step—the densities likewise show an addition, which is the same at each step, although it may not be equal to that plotted on the log exposure scale. This is

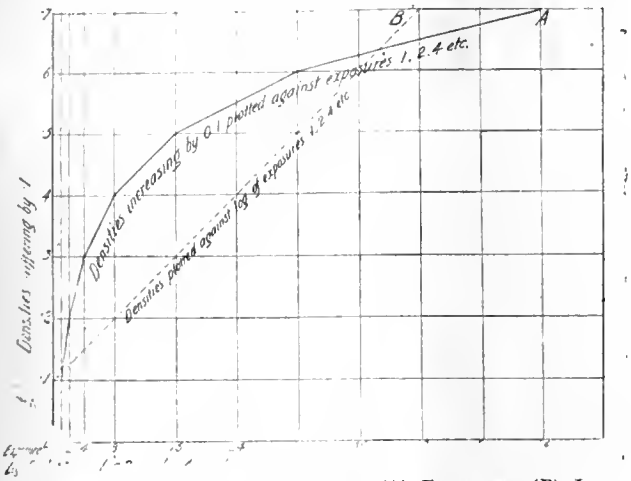


FIG. 5.—DENSITIES PLOTTED AGAINST: (A) EXPOSURES; (B) LOG EXPOSURES.

In the case of curve A, densities .1 to .7 are plotted against distances proportional to 1, 2, 4, 8, etc. In B, the same densities are plotted against distances proportional to the respective logs of 1, 2, 4, 8, etc.

shown in B, fig. 5, where the same density values are plotted against distances on the horizontal scale which are proportional to the logarithms of the exposures employed for curve A.

The scale of exposure logarithms (log exposures, as they are called) has another advantage. The difference between the logarithms is small compared with the difference between the numbers of which they are the logarithms. The logs of the numbers 1 to 8,000, representing a range of exposures which may be used in examining a plate, are respectively 0 and 3.9, so that by plotting log exposures instead of exposures the magnitude of the scale becomes of the same order of size as that of densities, and changes in the course of the curve are plainly evident within a small compass.

It may be asked—why not plot opacities against exposures, since these are like quantities, and, therefore, give a straight-line "curve" when plotted one against the other. But opacities vary in their ratio to one another with the progress of development, and therefore an opacity-exposure curve would vary at every stage of development. If we want to discover the limits within which a plate fulfils the conditions of correct reproduction as regards exposure and development separately, we must adopt a methed which first involves the first of these factors without the second. How that was done by Hurter and Driffield we can now see.

Charting the Growth of Density.

Hurter and Driffield were the first to perceive the usefulness of plotting the logarithms (or values proportional thereto) of exposures against the densities correspondingly produced by those exposures.

The density scale is conveniently one from 0 to about 2.5, since densities which are measurable with fair accuracy fall within these limits. It is divided into 10 divisions from 0.0 to 1.0, and so on, each representing a density of .1. Each of these divisions is sub-divided into fifths, so that densities can be plotted to an accuracy of one-fifth of .1 (=.02) throughout their scale.

The log exposure scale is not quite so simple. The numbers on the scale indicate candle-metre-seconds (C.M.S.) from .1 to 1,000, a range equivalent to 1 to 10,000, which is more than sufficient for exhibiting the properties of a plate which are of practical importance. But the *distances* laid off on the scale are made proportional to the logarithms of exposures (C.M.S.), that is to say, as each exposure is doubled an equal amount is added to the distance.

Since the exposures indicated on the scale become greater in increasing proportion along the length, the sub-divisions of the scale are made to indicate an increasing number of C.M.S. as one proceeds along the scale from the lower to the higher exposure values. In the form of chart originally devised by Hurter and Driffield the sub-division of the scale is as follows:—

Over portion of log exposure scale marked (exposures)—	each sub-division indicates.
.1 to .3	.01 C.M.S.
.3 to .7	.02 ,,
.7 to 1.0	.05 ,,
1.0 to 3.0	.1 ,,
3.0 to 7.0	.2 ,,
7.0 to 10.0	.5 ,,
10.0 to 30.0	1.0 ,,
30.0 to 70.0	2.0 ,,

and so on for the higher values. Apart from the necessity of marking the lower exposures (*i.e.*, their logs) with sufficient accuracy, it is of importance to be able to take an exact figure in this part of the scale, since, as we shall see in a later chapter, it is here that the *inertia*, by which the speed of the plate is rated, is measured.

A further little point concerning the log E scale may perhaps be usefully explained. As commonly plotted in sensitometric measurements the zero point, at the junction of the vertical and horizontal scale, the "origin" as it is called, represents .156 C.M.S. But as the distances on the scale correspond with the logs of these exposures, log 1 (= 0) represents a zero point and actually the distances representing logs of exposures from .99 to 0 are minus distances. However, this does not make any difference as regards charting the characteristic curve on a properly made scale since we are concerned simply with the values of the log E distanes. But in making this part of the scale oneself it is necessary to bear this point in mind and lay off the distances according to one or other of two plans, the basis of which is shown in the following table:—

E	log E (approx.)	
	a	*b*
.9	$\bar{1}.95$ =	− 0.05
.8	$\bar{1}.90$ =	− 0.10
.7	$\bar{1}.85$ =	− 0.15
.6	$\bar{1}.80$ =	− 0.20
.5	$\bar{1}.70$ =	− 0.30
.4	$\bar{1}.60$ =	− 0.40
.3	$\bar{1}.50$ =	− 0.50
.2	$\bar{1}.30$ =	− 0.70
.1	$\bar{1}.00$ =	− 1.00

NOTE.—In col. *a*, $\bar{1}$ represents − 1.00. The numbers in col. *b* are the differences (minus) between the respective positive decimal fractions and this − 1.0 *e.g.* − 1.0 + .95 = − 0.05.

In setting off the distances on the log E scale we can start from the extreme right (log .1 = $\bar{1}$.0) and successively measure off from left to right the distances .3, .5, etc., in col. *a* representing the positive (decimal) part of the logarithm; or we can start from the 1 (log 1 = 0) on the scale and successively set off distances representing .05, .15, etc., in col. *b* from right to left. The resulting scale will be the same in each case.

The two scales (density and log exposure) are also made equal, that is to say, the length between densities 1.0 and 2.0 is equal to that between a log of value 1.0 and a log of value 2.0, corresponding respectively with exposures 10 and 100, since log 10 = 1 and log 100 = 2. It will thus be seen that there is a strict proportionality between the two scales.

The Characteristic Curve.

If now the densities obtained by exposing a strip of plate to a series of increasing exposures be plotted on a chart devised as above and the points joined, the growth of density

is exhibited by a curve, which varies both in shape and in its position on the chart according to the particular quality of the plate, but almost invariably is of the *f* type shown in fig. 6. Hurter and Driffield called this the *characteristic curve* of the plate.

It is usual to make each exposure double the preceding one because that is found to provide a sufficient number

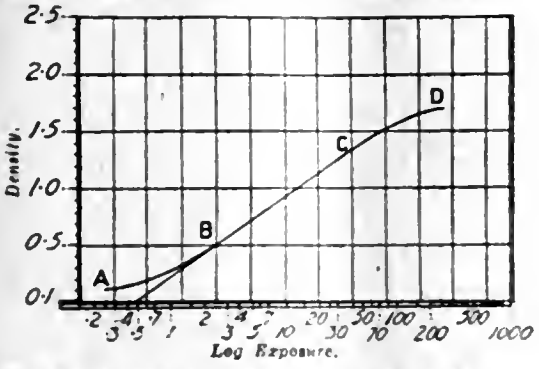

FIG. 6.—THE CHARACTERISTIC CURVE OF THE PLATE.

Densities are plotted against the logarithms of the exposures which respectively produce them. The upper ends of the lines representing density values, when joined together by an even curve, produce the characteristic curve of the plate.

NOTE.—The numbers are proportional to the exposures, but their distances from the zero point are proportional to the respective logarithms of the numbers.

of points from which to build up the curve, but there is no necessity that the exposure should be doubled each time. If exposures are successively increased by a larger multiple than 2 a sufficient number of them may not be obtained within the range necessary to produce the characteristic curve. On the other hand, if the exposures are increased by smaller steps, a needlessly greater number of them will be required. But apart from this it is immaterial what the exposures are so long as their logarithms are plotted on the scale against the density produced by each. It is, however, the regular practice to double each successive exposure. Exposing discs are made to do that, and the system has the advantage of giving a series of C.M.S. values which are quickly found on the log exposure scale.

Providing that a sufficient range of exposures be given, the characteristic curve of any plate exhibits (with variations) the three phases to which allusion has already been made. In the part A B corresponding with the least exposures it rises slowly. The addition to density at each successive increase in log of exposure is small, but increasing. This is the period of under-exposure, during which the growth of density is directly proportional to the exposure. Next the "curve" becomes (BC) practically a straight line; each successive density receives an addition proportional to the increase in the corresponding log exposure. This phase was named the *period of correct representation* by Hurter and Driffield and is now commonly spoken of as the *period of correct exposure*. The latter term is the better one, for the straight line does not signify correct representation, but a proportionality of density difference to log exposure difference which make correct representation possible by suitable development, and is a necessary preliminary to development to the *correct* degree. In other words, the difference between successive densities is (usually: short development) smaller than the difference between the logs of the producing exposures and in a constant proportion thereto.

The final phase of the curve is one of reduced slope, C D. The density ceases to obtain the same addition with each successive multiple of exposure, but a constantly smaller addition, which, if exposures are greatly continued, may even become a subtraction of density. Neglecting, however, this latter reversal phase, the upper less steep part of the curve in fig. 6 is the period of over-exposure, in which densities tend to show less and less increase for equal increases in the logs of exposures.

There is, of course, no sharp demarcation of these three phases: they merge imperceptibly into each other, but the correct exposure portion, in the case of almost every plate, is a straight line of such length that it can be used, as will shortly be shown, for measuring an important quality of the plate, viz., latitude, and, as we shall see later on, speed.

Translating the Imagery of the Characteristic Curve

Perhaps a difficulty felt by students of sensitometry is in becoming familiar with the form in which facts are described by the characteristic curve of the plate. It may, therefore, be desirable to say something which will help to show the meaning of the curve in relation to the conditions under which plates are exposed.

As we have seen, the curve is a picture of the varying rate at which increasing exposure produces increased density. The series of exposures *successively* given to different parts of the plate is an artificial and definitely repeatable substitute for the series of exposures *simultaneously* given to different parts of the plate in the camera. In fact, the artificial exposures need not be successive; they also can be given simultaneously by means of a screen, different parts of which transmit light in known relative intensities. The significance of the curve can perhaps be better displayed by representing it as a series of steps of a staircase (fig. 7), the height of each step representing the addition to the density produced by a doubled, trebled, or otherwise multiplied exposure, of the different parts of the plate. It is seen that the steps first become higher and higher, then remain at the same height, and then progressively become lower as we trace the effect of increasing exposure. If we imagine Nature to be a cubist artist in the design of her landscapes, we can conceive a scene different parts of which emit light-intensities in such sharp proportion as 1, 2, 4, 8, and so on. And as all would act on the plate in the camera for the same time, exposures would be in the same proportion, comparable with those from an artificial exposing screen.

This hideous cubist landscape being imagined, what is the meaning of the characteristic curve? It is that if the time element in the exposure is small, so that the plate is exposed not much more than is requisite to produce any

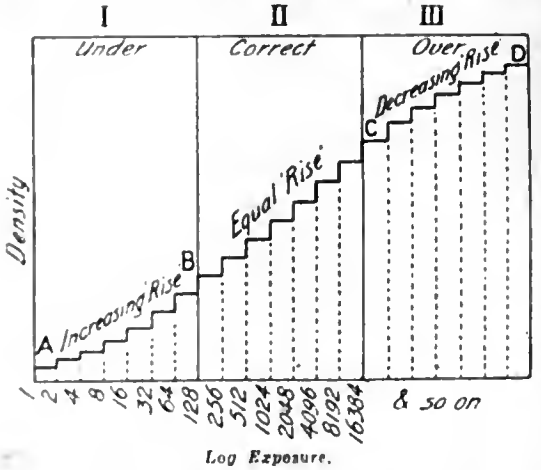

FIG. 7 HOW DENSITY IS ADDED AS EXPOSURE IS MULTIPLIED.

In II. (correct exposure and correct development), increase in density at each step is equal to the increase in log exposure. In I. (under-exposure), addition of density is *greater* at each *equal* increase in log exposure. In III. (over-exposure), addition of density is smaller at each equal increase of log exposure. (Hurter and Driffield.)

effect at all, the density differences increase more rapidly than they should for any development to give correct representation. Relatively there is too much density in the part of the negative representing the lightest part of the subject and not enough in the darkest part for a true relative representation. In photographic language, dense high-lights (of the subject) have too great a difference from the middle tones,

and bare shadows (again, of the subject) have insufficient differentiation of such tones; in other words, the well-known marks of under-exposure became evident on development.*

It is necessary to allow the light-intensities to act for a longer time in order that the plate receives such an exposure that increase of density is related to the exposures as shown in the middle part of fig. 7, that is an *equal* addition to each of the deposits representing light-intensities in the proportion of, say, 1, 2, 4, 8, etc., the resulting densities jumping from step to step by an amount which is constant and proportional to the increase in the corresponding log exposure.

And what happens if a still longer time is allowed for the light-intensities to act? It is depicted in the third part of fig. 7. A regularly falling increase of density marks the action of the light-intensities in proportion 1:2:4:8, etc. The step between each density is less than it should be for a correct relative representation of the light-intensities; in other words, the flat effect of over-exposure.

We have conceived a subject of abrupt tones in order to express sensitometric results in terms of camera exposures, but it is self-evident that what is true of such an arbitrarily imagined subject is true also of one consisting of a multitude of softly gradated tones. The emitted light-intensities, however little they differ from one another, require to act for more than the minimum time requisite to produce an under-exposed negative in order that their effects in relation to one another may fulfil the first condition of correct representation, viz., increase of density in proportion to increase in log exposure. But they must not act for so long that their effects cease to fulfil this condition and exhibit the results of over-exposure. Between these two times lies the period of correct exposure, which may be great or small according to the particular quality of the plate and the character of the subject. Here we approach the question of latitude, to which we must next turn in order to see that it can be expressed in a definite way.

Before we do that the diagram, fig. 7, requires a word or two of comment respecting one feature of it which may mislead the beginner. It may suggest that for the correct representation of a series of light-intensities of 1 to 128 shown under-exposed in part I. of the diagram exposure must be such that the *lowest* density must be at least a little greater than the *highest* density in a wholly under-exposed negative (I.). Every photographer knows such is not the case and therefore will be inclined to regard the diagram as a misstatement of fact in this respect. But the gradations you see in a negative are the opacities, not the densities which are plotted in fig. 7; and densities are small compared with the opacities they produce. It will be clear that you can have a series of low densities (related to another series as in fig. 7) which on development can give rise to a negative in the straight-line portion having a series of opacities, the lowest opacity in which need not be as great as the highest opacity of a negative in the under-exposure portion. Nevertheless, the diagram does indicate, though obscurely, that a negative which is correct in its gradations must have received a greater degree of exposure, must therefore have greater densities in its shadow tones, and therefore must have appreciable opacities in these tones. In other words, the negative corresponding with the straight-line (correct exposure) part of the curve has perceptibly different deposits (opacities) over its shadow tones. These need not be as great as the greatest in an under-exposure negative; that is a condition dependent on development.

* We are here leaving out of consideration for the moment the effect of development in bringing the ratio of densities into correct correspondence with the light-intensities as regards transmission of light. This has been touched upon in the earlier paragraph "Exposure, Development and Density," and we will return to further consideration of it directly.

Latitude.

The term latitude is employed in two distinct senses: (1) latitude of the plate—a property or quality of a plate—and (2) latitude in exposure—the relation of the degree of that quality to the range of light-intensities from the subject. Many photographers appear not to distinguish between these two conceptions of latitude, failing to recognise that latitude in exposure depends on the subject as well as on whatever merits the plate may possess in this respect.

As regards the latitude quality of a plate, it is customary to take approximately the straight part of the characteristic curve, or rather the range of exposures corresponding to this part of the curve, as a measure of it. In fig. 6, for example, the portion of the curve from about 1.5 to 80 may be considered straight. This is equivalent to a range of exposures of about 1:53. Hurter and Driffield were of opinion that for practical purposes a part of both the under-exposure and over-exposure sections of the curve might be included in the latitude without materially affecting the results, and on this basis, in the above example, would have considered the latitude as equal to about 1:148. Of late years, however, it has become customary to rate latitude more strictly, *i.e.*, to express it by the range of exposures corresponding with the actually straight part of the curve.

Latitude in exposure is obviously dependent on the magnitude of the range of light-intensities from the subject in comparison with the magnitude of the latitude of the plate. Hurter and Driffield, by actual measurements, satisfied themselves that the range of light-intensities from the different parts of a landscape was much smaller than had previously been supposed. They found, for example, that the sky of a brightly lighted landscape reflects light of only 30 times the intensity of that from a very dark object in the foreground; that is to say, the range is 1:30. The ratio of the range of exposures (corresponding with the straight part of the curve) to the range of light-intensities from the subject is therefore a measure of the latitude in exposure. If the exposure range is 1:60 and the subject range 1:30, the latitude is 2; which means that if an exposure of one second was sufficient for minimum correct exposure, 2 seconds would give an equally correct result, differing from the former only in the fact that the negative as a whole would be denser and therefore take longer to print.

It will thus be seen that with a plate of good latitude correct exposure, as Mr. Watkins has aptly written, "is an enclosure rather than a spot." So long as exposure falls within the correct exposure part of the curve, it is immaterial where, except as regards the printing speed of the negative. If the subject-range of light-intensities exceeds the latitude of the plate, *e.g.*, in interior subjects, including windows, something must be sacrificed at one or both ends of the scale by giving such an exposure that part of the subject range is recorded in the under-exposure or in the over-exposure part of the curve.

G. E. B.

(To be continued.)

New Spanish Customs Regulations.—By Royal Decree published on June 4 the Spanish Government has increased the co-efficients on importation duties on goods from countries with depreciated exchanges. The increase varies from 10 to 70 per cent. The system devised to apply this Decree is an ingenious one (says the "Times" Madrid correspondent), and ensures a measure of justice, the idea being to apply the greatest surcharge where the exchange suffers the greatest depreciation and where, for that reason, the greatest facility exists for dumping. The new Decree re-establishes many articles of British goods on a more equal footing for competition in the Spanish market by compensating for the hardships imposed by the duties under the recent provisional tariff in combination with the exchange barrier. It should, therefore, encourage British manufacturers to redouble their efforts in the Spanish market so as to profit by the changed outlook and the opportunities it affords.

PARIS NOTES.

Autochromes in Advertising.

A most interesting and deservedly successful new departure has recently been made in bringing many of the chief French luxury trades to the notice of the general public. This has been done by means of the Autochrome process, which, in serving the purposes of advertisement, has itself obtained considerable *réclame*. The "Salon of French Taste," which opened last month in the Palais de Glace, Champs Elysées, Paris, contains more than 1,800 Autochromes of all sizes, from 7 × 5 inches to 16 × 7 inches (the largest size made), representing jewellery, glass and pottery ware, enamels, bookbinding, tapestries, furniture, lighting accessories, and all articles of dress and toilet, and even carriage work. These Autochromes, in company with a number of coloured transparencies from 14 × 10 to 24 × 20 inches, are mounted in frames and are illuminated by concealed electric lamps. The colour reproductions of the goods of each of 250 exhibitors occupy a separate panel, and these panels are systematically arranged in twelve alcoves erected in the rotunda of the Palais de Glace. The conception and organisation of the whole exhibit have been perfectly carried out in all respects, and reflect the greatest credit upon its designer, M. Devries, and equally upon the makers of the Autochromes, MM. Desboutins and Ventujol. The exhibition has been a revelation of colour photography, and the Autochrome process to the public unfamiliar with photography; and the reviews in the newspapers have shown a widespread ignorance, on the part of the Press, of the existence of the Autochrome process. One daily journal refers to it as "having apparently been invented by someone named Lumière about the year 1907." The exhibition remains open until the end of September, and I can strongly recommend any of my readers who may be passing through Paris this summer to set aside an hour for a visit to it. After it has come to an end in Paris, the exhibition is to be transferred in turn to the capitals of several countries in which French luxury goods find their principal markets, and hence has been dubbed "an exhibition in a portmanteau."

The Paris Fair.

Although the Paris Fair is this year of much greater size than previously, the photographic industry obtains very small representation in it. The few exhibitors are grouped in the corner of the Esplanade des Invalides, which nominally had been assigned to photography. The chief exhibits are "As de Trèfle" plates and papers of MM. Grieshaber, lenses Berthiot and other optical instruments and hand-cameras of the Société d'Optique et de Mecanique de Precision, cameras and accessories of Demaria-Lapierre, cinematograph appliances by M. Mendel, photo-engraving by Dujardin, and other accessories, such as frames, albums, dry-mounting materials. In the mechanical and electrical sections are several models of photocopying (blue-print), and cinematograph printing machines. In these same sections, and forming part of the exhibit of the official Department of Scientific and Industrial Researches and Inventions, is shown an Autochrome photograph by Dr. A. Polack, an oculist of repute, but apparently a very indifferent photographer. This has been produced with an anachromatic lens, which is pompously described as a "hyperchromatic" objective, the French and German patents of which declare that "the uncorrected rays, diffusing into the image of the red, compensate for lack of red-sensitiveness in the plates employed." The result obtained, as was readily to be anticipated, is not at all promising.

Combined Development and Fixing.

A French chemist, M. L. J. Bunel, living in Italy, whose name is well known in connection with uranium toning, has recently worked out a formula for simultaneous development and fixing which, I think, is the first step towards a really satisfactory form of this process. It employs chemicals in common use, and is readily compounded. As with previous processes of this kind, it is necessary that the exposures should be ample, otherwise fixing is completed before development has proceeded far enough. The following developing solution is made up at the time of use:—

Soda sulphite, dry	30 gms.
Diamidophenol (hydrochloride)	5 gms.
Hypo	50 gms.
Acetone	80 ccs.
Water to make	1,000 ccs.

I have obtained some excellent vigorous and well graduated negatives with the above formula, which, moreover, works perfectly with plates or films desensitised with safranine.

Keeping Qualities of Developers.

Another French chemist, M. J. Desalme, who has previously made several contributions to the subject of developers and development, has published a process which he has had in use since 1912 for preventing the oxidation of the ordinary developers, which can be used until the accumulation of bromide in the course of development renders them too slow in action. M. Desalme, after a systematic study of many reducing substances able to regenerate the developer from its products of oxidation without acting either on the latent image or the unaffected silver bromide, and also capable of addition (without precipitation) to developers containing sulphite and alkaline carbonates, has made choice of a double soda-stannous tartrate, which he prepares as follows:—Dissolve 10 gms. crystallised stannous chloride and 15 gms. powdered tartaric acid in 50 to 80 c.c.s. of boiling water. After cooling to nearly the ordinary temperature, pour this solution slowly and with constant stirring into a cold solution of 25 gms. dry soda carbonate in 250 c.c.s. of water. Make up to 400 c.c.s., let stand for at least 12 hours and filter. This solution is used in conjunction with alkaline developers by adding about 40 c.c.s. to each 1,000 c.c.s. of the working developer. In using it with developers, such as diamidophenol, not suitable to the employment of a strongly alkaline salt, the stannous tartrate solution is first neutralised, or very slightly acidified by addition of sodium bisulphite up to a point at which the mixture, after thorough stirring, slightly renders red the blue litmus paper. I have been able to keep diamidophenol developer "preserved" in this manner in good condition for over a week in an open vessel, whilst similar but unpreserved developer was useless within less than an hour. Although the stannous tartrate compound decolourises many dyes, it has no action on safranine, and it does not interfere in any way with the desensitising powers of these dyes.

My experiments with alkaline developers, other than a special developer (quinol and paramidophenol) commended by Mr Desalme, have not had the same success.

Stereoscopic Projection.

A great deal of interest is now being taken in stereoscopic projection, and a meeting of the French Photographic Society has been held for showing anaglyphs made by M. L. Gimpel on Autochrome plates. Although this method of production is, as I think, neither the best nor the most economical, it must be admitted that the results shown were truly remarkable, and, when at the end of the exhibition, those who had taken part and had not seen the relief on the screen were asked to raise their hands, not a hand was put up. While it may be possible to make stereograms direct from nature in this way by two exposures in register (this obviously limits the scope to subjects without movement) it is better to produce the anaglyph by reproducing in two successive positions the two images of an ordinary stereoscopic transparency. If, in accordance with the usual custom, the eye-pieces used for the inspection of the images provide a green screen for the left

eye and a red screen for the right, the left-hand image of the pair is reproduced on the Autochrome plate through a deep red screen such as the Wratten F., thereby allowing light to act only through the red grains of the mosaic filter layer. The right-hand image is then printed either successively through green and blue screens such as the Wratten N. or L. or at one operation through a blue-red screen such as "Minus red 4," so as to act upon the emulsion through the green and blue grains of the mosaic filter, the two images being thus complementary to each other. In order to ensure suitable register of the two images, which register, as a rule, will be made on the foregrounds in order that the subject may appear as though viewed through a window formed in the plane of the projection screen, focussing is done with the ground glass reversed (that is to say, the normal position for correction of focus, the Autochrome plate being exposed through the glass), and on the ground glass are pencilled a few marks outlining the foregrounds. The first image having been printed, the negative holder is replaced for a moment by the ground glass and the position of the second image so adjusted that it coincides satisfactorily with those marks. It will be noticed that from the fact of the reversal of the two images, the colours of which are added to each other instead of subtracted from each other as in the case of the assemblage of pigment images, the image printed under the red screen will appear, after the usual reversal, as green on a white ground, whilst the image printed under the green screen will appear in red on a white ground. The inspection of the images themselves, or on the projection screen, is done by means of a card, with two holes in it, providing a red screen for the right eye and a green screen for the left eye and corresponding as closely as possible with the Wratten A. and "minus red 4" screens. These screens can be made by dyeing fixed and washed films. A mark is made on each card to show the side which should face the observer.

At the same time I cannot help thinking that it is simpler and more economical to make these anaglyphs by superimposing two actual positive transparencies prepared on film, *e.g.*, Process film. The transparencies are respectively toned to red and green by the mordant dye process of Ives described in the "B.J. Colour Supplement," Jan. 7, 1921, p. 3.

Cinematography for Amateurs.

There has just been placed on the market, under the name of "Sept," an ingenious camera for the taking of cinematograph pictures by amateurs, and serving also for making single different pictures and also for the printing and projection of the cinema films. The apparatus, which is made in accordance with the patents (1908) of J. B. Tartara, is entirely automatic, and under good conditions can be used in the hand. It uses standard cinematograph film of about 15 ft. length, the 250 pictures obtained occupying about 15 seconds for projection, which allows of showing many interesting scenes. The spools are loaded in full daylight by means of special boxes of very simple construction, which avoid all friction on the film, the aperture in the spool-box being opened, after the box has been loaded, by a device outside the camera. A large number of very satisfactory films obtained by different amateurs was shown at a recent meeting of the French Photographic Society on the occasion of the camera being described. The apparatus has a mechanism which essentially is a Maltese Cross, but exact register of the pictures is ensured by a pin, which is caused to enter the perforation of the film at each instant that the shutter is on the point of opening, and thus corrects any error of position. And it may be added that the apparatus is made by the firm of Debrie, universally known for the high standard of its apparatus and projectors for cinematography.

L. P. Clerc.

The Affiliation Outing.—The affiliation of Photographic Societies' annual outing will take place on June 25, the ground selected being the Dorking and Betchworth districts. A capital map and programme giving the most minute details has been issued.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications May 30 to June 4 :—

Roll Films.—No. 15,384. Support of photographic roll films. C. W. R. Campbell.

Development.—No. 15,385. Means for development of photographic negatives or positives on glass plates. C. W. R. Campbell.

Lens Mountings.—No. 14,956. Lens mountings. C. H. Clarke.

Glazing.—No. 15,184. Preparation for glazing photographs. J. V. Cook and Photographs (Birmingham), Ltd.

Cameras.—No. 15,257. Cameras and easels. E. A. Green.

Camera Device.—No. 15,059. Camera-holding device. G. V. Massey.

Sound Recording Apparatus.—No. 15,377. Photographic apparatus for recording sound. H. G. Matthews.

Sound Reproducing Apparatus.—No. 15,378. Photographic apparatus for reproducing sound. H. G. Matthews.

Cinematography.—No. 15,104. Cinematographic picture taking and projection apparatus. Cinemundi and E. C. R. Marks.

Cinematography.—No. 14,997. Manufacture or cinematograph films. A. C. Coppier.

Cinematography.—No. 15,403. Cinematograph apparatus. G. S. James.

Cinematography.—No. 15,356. Cinematograph projectors with automatic rewinders. J. B. A. E. Peranne.

Stereoscopic Cinematography.—No. 15,193. Stereoscopic or curved screens for cinemas, etc. D. B. Procter.

Stereoscopic Cinematography.—No. 15,445. Stereoscopic cinematography. E. H. Wright.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Changing-Boxes.—No. 144,605 (June 12, 1919). The invention relates to changing-boxes of the type in which films are drawn by means of tabs out of a compartment having an exposure aperture into a rear compartment in which they are retained, pending removal at a convenient time in a dark room.

The ends of the tabs, in changing-boxes of this type, project through an aperture of the rear compartment, and a usual method of making a light-tight joint at this aperture is to use a kind

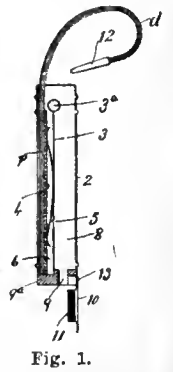

Fig. 1.

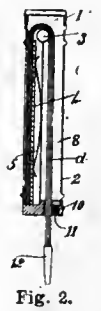

Fig. 2.

of valve comprising a strip of plush, which bears against the tabs.

According to the invention, the slot through which the tabs pass has a lateral enlargement, and the strip of plush is attached

to an arm pivoted to the box so that the strip can be rocked into, and out of, this enlargement.

In the drawings, the metal box 2 has a lid 1, fitting the top with friction and making a tight joint. This lid can be pulled off and replaced with a slight effort. The interior of the box is divided into two compartments by a wall 3 having a cylindrical guide bar 3a at the top, under the lid 1. In the front compartment 6 there is the usual packing plate 4, thrust by a spring 5 towards the front wall which has an exposing aperture 7. The floor 9a is provided in the rear compartment 8 with a slot 9, and is in part cut away at one side of the slot to form a gap or enlargement of the slot, as shown in figs. 1 and 3. A short metal arm 10 having a strip of plush 11 or the like attached to one side of it is pivoted at 13 to the back of the box, so that it can swing away from the floor, as shown in figs. 1 and 3, or lie parallel with the slot 9, as shown in figs. 2 and 4. In the latter position it is held by a catch, and the strip 11 lies in the enlargement of the slot.

The films *p* are attached in the usual manner to sheets of paper having long tabs *d*, which may be numbered. Twelve or any other convenient number of films are made into a pack, and the tapered ends of their tabs *d* are then enclosed in a metal sheath or clip 12. With the lid 1 of the box removed, as shown in fig. 4, the films are inserted into the front compartment 6, the packing plate 4 being pushed back for this purpose and then allowed to bear against the rear of the pack. The tabs, held together by the clip 12, are then passed over the guide

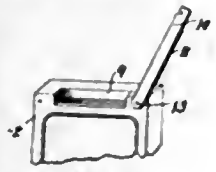

Fig. 3.

Fig. 4.

bar 3a through the compartment 8 and through the slot 9, the arm 10 being swung down for this purpose. Then the arm 10 is swung up, so that the strip 11 is pressed against the tabs and makes a light-tight joint, and the lid 1 is put on. The clip 12 can then be removed by a sharp pull. When an exposure has been made, the tab of the exposed film is pulled, so that the film is drawn over the bar 3a into the compartment 8, in which it is usually left till all the films have been exposed and collected in this compartment. Then the films are taken out, in a dark-room, in order to be developed, and the box can be filled again with another pack of films having a clip 12.—Société Anonyme des Celluloses Planchon, 237, Cours Gambetta, Lyons.

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JUNE 20.

South London Phot. Soc. "Toning Bromide Prints." W. J. Shields.

TUESDAY, JUNE 21.

Hackney Phot. Soc. "Bromoil." J. W. O. King.
Manchester Amateur Phot. Soc. "One Man Show of Prints and Lantern Slides." J. D. Berwick.

THURSDAY, JUNE 23.

Kinning Park Co-op. Soc. Open Night.
Hammersmith Hampshire House P.S. "Mounting the Print." G. C. Weston.

SATURDAY, JUNE 25.

Kinning Park Co-op. Soc. Outing to Glasgow Harbour.
Hammersmith Hampshire House P.S. Affiliation Outing to Dorking.
Glasgow and West of Scot. Outing to Islands of Loch Lomond.
Manchester Amateur Phot. Society. Ramble to Warburton Church and Canal Side.

CROYDON CAMERA CLUB.

The informal session started last week with a capital lecture by Mr. S. W. Rose on "Paget Colour-Screen Plates." Many fine slides by the Paget Co. and the lecturer were shown, those of the latter, by general consensus of opinion, in most cases equalled, and in one case surpassed, any of the loan collection. Some interesting examples of the now defunct Thames plate (which may be said to have been the father of the Paget) were also passed through the lantern.

It is not necessary to follow Mr. Rose through his clear exposition of a well-known process, but some points arising may usefully be mentioned. Beginners, he said, should note that colour transparencies made for viewing by daylight are generally not the best for projection. For the latter, slides inclining to thinness and dullness of colour seem to show best on the screen. He had found that after correct registration is apparently obtained, a further minute refinement of adjustment, so to speak, will perceptibly change shades of colour. It also transpired, doubtless due to the difficulties experienced by all manufacturers in this "do, as you would never wish to be done by" country, that the Paget Co. are in arrears with colour plate orders, and speedy delivery cannot be guaranteed.

The reference to the too blue hue which the greens occasionally acquire, Mr. L. J. Hibbert pointed out that dyeing the positive a pale yellow often puts matters right. Naturally, one is not tied to this colour, for if, for instance, the prevailing tone of a slide happens to be too yellow a blue dye may effect a cure. The "Dolly" dyes, he said, are handy and supplied in various colours.

On the question of rapidity *versus* colour correction, it was pointed out by Mr. J. W. Purkis that comparatively heavy screen-plate colours are necessary for full correction, and, other things being equal, this condition slowed exposure. The Autochrome was an example of heavy colours. Mr. N. Moody stated he had tried "Desensitol" with the Paget plates, and successfully; the preliminary bath seemed to slow development somewhat. Mr. A. F. Wood was sadly distressed that no information was forthcoming about tank development, which cast the only shadow on the evening. Mr. H. P. C. Harpur thought that colour plates at present prices formed a gorgeous tonic for inducing care in exposure. Failing colour work, 15 × 12 dry-plates used in the field would be found equally effective.

It happened to be the birthday of the president, Mr. John Keane, who celebrated the occasion by directing that all obligations incurred in the purchase of bath buns, lemonade, and other commodities from the refreshment department should be met by his personal exchequer. Congratulations were the order of the day, Mr. G. H. Gardner, however, expressing sympathy that the birthday happened to drop expensively on a Wednesday. This led the tender-hearted "office boy" to inquire anxiously whether others were similarly afflicted. The evening terminated with a hearty vote of thanks to Mr. Rose.

News and Notes.

Masks and Photographs.—Do you know the latest photographic pose? asks the "Daily Mirror"; we are then told that "You face a wall and then look over your shoulder at the camera And on the wall must hang the oddest and most grotesque mask to be found. You shine by contrast, even if you are not very beautiful!"

The Scottish Photographic Circle.—An exhibition of pictorial photography will be held in the rooms of the South Glasgow Camera Club, 43, Bankhall Street, Govanhill, Glasgow, from December 3 till 17, 1921. Full particulars may be obtained from the Hon. Secretary, Mr. W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

Miss Olive Edis had the honour of giving a private view to H.R.H. the Prince of Wales, at York House, St. James' Palace, of some of the colour-photographs taken during her recent tour in Canada under the auspices of the Canadian Pacific Railway. H.R.H. expressed keen interest in the views, and the colourings of the lakes and the Rocky Mountains, and accepted some of his favourite views.

Marion's New Productions.—The current issue of Marion's "Professional News" describes a new portable electric light studio which can be packed in a case no larger than a golf bag, also a new "soft focus" single achromatic lens designed with all the features necessary for the production of soft effect portraits. The latest prices of chemicals are also given, and we notice many reductions. A copy of the list may be had on application to the firm, 3, Soho Square, London, W.1.

The "Kodak Trade Circular" (with supplement) for June deals in an interesting way with window displays; it states also that the manufacture of "Libra" bromide postcards, which had to be suspended owing to the difficulties of war-time, has now been resumed. "Libra" cards can be supplied in singles and strips, but, unless ordered otherwise, quantities of one thousand and upwards will always he sent in strips of 21½ ins.; the cards are not supplied in packets for retail sales.

Fireproofing Flashlight Smoke-Bags.—The following formula, according to "Camera Craft," is the one used for fireproofing flash-bags by one of San Francisco's commercial photographers, who highly recommends it:—Ammonium sulphate, 8 parts; pure ammonium carbonate, 2½ parts; boracic acid, 3 parts; gelatine, 2 parts; water, 100 parts. The fluid is heated to 85 deg. F., and the material (nainsook) immersed in it until thoroughly permeated It is then slightly wrung and dried sufficiently for ironing. The quantity of gelatine may be changed according as the material is to be more or less stiff.

A New "Criterion" Booklet.—A most artistic, and useful booklet comes to us from Criterion, Ltd., Stechford, Birmingham The publication bears the title, "A Treatise on the Art and Practice of Photography," and consists of forty-eight pages (8 x 6½ in.), bound in a three-colour pictorial cover. The author, Mr. William Bell, deals very cleverly, and in a chatty, free-and-easy manner with many branches of work, including bas-reliefs, retouching, bromoil, carbro and press photography. A copy of the book may be obtained by applying to the firm and enclosing two-pence for postage; early application is advisable, as there is sure to be a huge demand for it

Photographing Groundsel.—Writing in the "Yorkshire Post" on the art of photographing weeds, Mr. F. M. Sutcliffe says:—"In weed photography there will be difficulties to be overcome, as in other branches of the craft. There is the difficulty of the gardener, to whom weeds are nothing more. You pull hold of his shirt sleeve and bawl into his ear—it is odd how deaf all good gardeners are—'You see that bit of groundsel there. Just leave it alone, will you, for a day or two? I want to photograph it.' On the morrow you take out your camera, the wind having gone down, and find your ideal groundsel plant has disappeared. When you tackle the culprit, he only says: 'Yes, I heard what you was saying of, but I thought it was only your fun.' As if photography had anything funny about it." The concluding sentence of the article is but one of the many useful tips contained therein, namely, "An empty snail shell will look better to show the height of each specimen (of weed) than a foot-rule stuck in the ground."

A Playroom Studio.—The proprietors of a large store in Pennsylvania have added a photographic studio to their children's department. Instead of fixing up a photograph gallery, the firm installed a children's playroom. The youngsters who have been made ready for their pictures are taken into the playroom, where toys are scattered on all sides. They are encouraged to play with them and be natural. All the time the photographer is busy getting some exposures with a reflex camera, and, with few exceptions, they are pronounced the most life-like that the parents ever saw. The children do not know they have been snapped, and the feature is advertised as an aid to young mothers, and brings them as shoppers to the store.

Portraits by Telephone.—An Exchange wire from Paris published in last Sunday's papers, stated that all the chief officials of the Paris police attended at the "Matin" office a few days ago to witness experiments in the latest scientific methods to aid in the speedy arrest of criminals. Photographs of fingerprints were sent over the telephone wire from Lyons to Paris. Within ten minutes of the commencement of the experiment proofs were in the hands of experts, who pronounced them excellent. The second test was the sending of portraits by telephone. The transmission occupied barely eight minutes, and the pictures obtained were as clear as the original Prof. Balthazard, who witnessed the experiment, expressed his admiration to M. Belin, the inventor of the system, who stated that in the near future it would be an easy matter to send photographs of fingerprints and portraits across the Atlantic.

Economy of Water.—Partly in consequence of the coal strike, which has curtailed the pumping powers of the water companies, but principally through the lack of rain during the past few weeks, the reserves of water available for use in London have been seriously depleted. The Ministry of Health has, therefore, notified to the Metropolitan Borough Councils that it is necessary to conserve the water supplies to the utmost. Photographers can assist in this direction by keeping a careful eye upon their taps and taking care that no more water is used for print and plate washing than is absolutely necessary. In most establishments at least four times as much water as would do the work is habitually used, and owing to defective methods, even then the washing is not thorough We have repeatedly pointed out the efficacy of washing with changes of water, especially in the case of prints, as compared with the usual method of letting a tap run into the dish or tank without moving the contents. In case of a serious shortage we may remind our readers that the use of hypo. eliminators, such as Hypono or Milton, allows of perfect washing with the use of a very small quantity of water, and, moreover, with a great saving of time.

The P.P.A. and the New Postal Taxes.—Protests against the proposed new postal charges continue to be showered down upon the Postmaster-General from all parts of the United Kingdom. The letter sent from the Professional Photographers' Association read as follows:—"The Rt. Hon. F. G. Kellaway, M.P., Postmaster-General, House of Commons. Sir,—I am directed by the Council of the Professional Photographers' Association of Great Britain, which is the representative organisation of photographers in this country, to communicate with you upon the subject of the proposed increase in postal charges. The members of this Association view with consternation the proposed increase, as it will particularly injure the business of photographers and result not only in a loss to them, but in a considerable reduction in the revenue which the country derives from the use which photographers generally under existing circumstances make of the facilities afforded by the post office for the distribution of printed trade matter, and the transaction of business by means of postcards. I am instructed to point out that the proposed increase in the charges for postcards will very seriously affect the volume of trade in photographic postcards, which from the point of view of the public are a luxury, and as such can be dispensed with if their use is rendered expensive. I am to request that your serious consideration may be given to the before-mentioned aspects of the matter and to urge that postal charges should be reduced (to the advantage and profit of the country and its revenue) rather than

that they should be increased to the serious detriment of trade generally and the revenue derived from postal service.—I am, sir, your obedient servant, LANG SIMS, Secretary."

METRIC SYSTEM ADOPTED IN JAPAN.—The "Board of Trade Journal" states that the new Weight and Measure Law as passed by the Diet was formally promulgated recently by the Japanese Government, thus rendering Japan one of the metric countries. Simultaneously with the promulgation of the new Law, Director Kitsukawa, of the Weight and Measure Office, gave out a statement saying that even when the first weight and measure law was framed in 1893 Japan was desirous of adopting the metric system, but the nation was not ready to accept it, and the old systems were fully adopted. "Several times since, the wholesale reform of the weight and measure systems has been attempted," the official's statement continues, "but it was quite difficult before the war to break with the old systems and adopt the new one to which the nation was hot little accustomed. When the world war started, however, the necessity of adopting the metric system was keenly felt and the Government Bill was readily accepted by the Diet." According to the Yokohama Chamber of Commerce "Journal," within the five years beginning with the date from which the Law takes effect all public works, Government offices, schools and large factories will be made to adopt the new system, while the general public will be given 20 years' grace.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.—A preliminary programme of this year's meeting of the Photographic Convention to be held at Bristol, from July 4 to 9, under the presidency of Mr. C. H. Bothamley, has been issued. The arrangements, subject to additions and alterations, are as follow:—Monday, July 4: Members attend headquarters at the Merchant Venturers' College, Unity Street, to sign the visitors' book and obtain tickets for excursions and the annual dinner, etc., and members of the Bristol and West of England Amateur Photographic Association and of the Bristol Photographic Club will conduct parties to places of interest in the city. At 3 o'clock, in the Merchant Venturers' College, the Lord Mayor will welcome the members of the P.C.U.K. to Bristol; installation of the president, who will deliver his inaugural address; election of new council. Reception at the Bristol Art Gallery in the evening at 7.30. Tuesday, July 5: Excursion to Gloucester, where permission to photograph in the Cathedral has been kindly granted by the Dean; lecture in the evening, by Mr. C. F. W. Dening, on "The Old Houses of Bristol," with lantern illustrations. Wednesday, July 6: Bristol Cathedral, in which permission to photograph has been kindly granted by the Dean; St. Mary, Redcliffe, where permission to photograph has been kindly granted by the Revd. J. N. Bateman Champain. In the afternoon visits will be paid to the tobacco factories of Messrs. W. D. & H. O. Wills, and to the chocolate factories of Messrs. J. S. Fry & Sons, Ltd. Arrangements are being made for an afternoon gathering at which the official group will be taken, and in the evening at 7.30, the annual dinner and smoking concert will be held at the Royal Hotel. Thursday, July 7: Long day excursion to Chepstow and Tintern, with lunch at Chepstow and tea at Tintern. As the hour of return from this excursion may be late, there will be no evening lecture, but an informal meeting may be arranged. Friday, July 8: Motor excursion to Bath and Lacock Abbey. At Bath the old Roman baths and the abbey may be photographed. After lunch, Lacock Abbey will be visited via Bradford-on-Avon; Lacock Abbey was the home of Fox Talbot, the contemporary of Daguerre and the pioneer of photography in this country; a collection of his early apparatus, experiments and work will be displayed at the Abbey for the visit of the Convention. In the evening there will be an illustrated lecture by Mr. C. P. Crowther. Saturday, July 9: The Bristol docks and shipping, and the Zoological Gardens, in addition to many other points of interest in the city, will provide a day's work with the camera. During the week an exhibition of pictorial photography will be held at the headquarters, the Merchant Venturers' College, and arrangements are also being made for a trade show and demonstrations. The programme, which is obtainable from the hon. sec., Mr. F. J. Mortimer, 56, Leigham Court Road, Streatham, S.W.16, also contains a comprehensive list of hotels and boarding houses, with tariffs.

Correspondence.

**** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

**** *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE PERSULPHATE REDUCER.

To the Editors.

Gentlemen,—In "Answers to Correspondents" in your issue of June 3, page 332, I notice that you recommend a formula for a persulphate reducer, with alleged keeping properties, containing sodium sulphite and sulphuric acid, at the same time expressing the opinion that the sulphite would be oxidised by the persulphate. Since this oxidation of course takes place, it follows that solutions of this and similar composition should be *less* permanent than a plain solution, and this was confirmed experimentally by Namias and Baschieri, "B.J." 1907, page 940, who showed that they possessed no advantages over the simple solution.—Yours faithfully,

G. I. HIGSON

British Photographic Research Association.

MICROPHOTOGRAPHY.

To the Editors.

Gentlemen,—In your "Answers to Correspondents" I notice a brief reference to microphotography—not photomicrography, be it noted—an almost forgotten branch of photography to which some further attention might be given.

Microphotography, however, was never very popular in this country, we always getting, years ago, a plentiful supply of specimens from the French, who were looked upon as being—as they undoubtedly were—past-masters of the art of microphotographic work. Indeed, I know of only one English worker who followed up the subject very closely and produced the most perfect results, this was the late Mr. J. I. Pigg, who just before his death was engaged upon a task of simplifying the now rather difficult process. One of Mr. Pigg's interesting examples was a page of the "British Journal" reduced down to one thirty-second of an inch, and every letter in this miniature reproduction of one of your pages could be read distinctly under the microscope; the examples he produced were in the form of microscopic slides, he being unable to obtain the small magnifying lenses used by the French manufacturers of penholders, etc., in which the miniature pictures were once commonly used. Perhaps one of your Parisian readers can tell us who makes or supplies the small "pin's-head" lenses, as all my efforts, both here and in France, to trace the manufacturer, have been in vain. It is just possible that the industry has disappeared.

As you say in your reply, a knowledge of the wet-plate process is necessary, but having this knowledge the actual making of the pictures is, I think, easier than many people imagine. Working instructions are extremely rare in photographic literature, and a few brief details of Mr. Pigg's method of working may be of interest, if not of service.

The most suitable objective is one of about 1 in. focus, and a camera is not required for the making of the very small picture, the prepared plate being fixed in the microscope stage and exposed in that position, the operation being carried out at night or in the darkroom.

A good negative—preferably a half-plate—of the original subject is first required, and this, of course, is taken in the usual way, and it is from this negative that the miniature positive is printed by reduction. The microscope, with the eyepiece removed and the objective in its place, is arranged in a horizontal position, and the negative placed about 24 in. from the lens, the open end of the microscopic tube facing the negative, the latter being arranged with ground glass so that the light comes through it as when enlarging, or reducing. The reduced image of the negative given by the objective is roughly focussed on a piece of white paper placed on the stage of the microscope, a strip of glass is then coated with collodion and sensitised, and then placed in the stage, the final and finest focussing being done with the help of a magnifier on the collodion, which, of course, will be fogged during the focussing. When the

correct focus has been found, the light is shut off, another portion of the sensitised slip—or a fresh piece—placed to receive the image and the exposure made. As it is so easy when all is arranged, it is advisable to make several exposures on the one strip.

As an exceptionally fine grain is necessary, pyro and acetic acid should be used as the developer, this developer giving a finer grain than the usual iron developer.

Such is the process in brief, the details, however, are quite sufficient for those who understand the microscope and wet-plate photography.—Yours faithfully. W. T. L.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. P.—There is no danger in using sea water for washing negatives and bromide prints provided you give a good rinse in fresh water afterwards.

P. E.—Many local newspapers do not pay more than has been sent you, and we daresay your people could show such are customary rates. Still, it might be worth while returning the remittance and submitting an invoice of 10s. 6d. for each print.

M. C.—We can hardly give you any useful information as to wages, as there are so many branches of work and in each varying degrees of efficiency. We do not think any decent firm would offer less than £3 weekly for a competent general assistant (male).

B. A. G —Stippling with zinc white is apt to slow the light, as the oil used soon turns yellow. A better plan is to use ordinary starch made as for mounting, mixed with a little whiting. This will not discolour, and you can easily wash it off for the winter. The Anschutz type of camera would be more convenient for your work. For a 5 × 4 about 5 or 6½ inches would be the best focal length. It is advisable to buy the camera ready fitted with the lens, as the camera has a fixed extension, and the focussing has to be effected by a screw movement. Even if you had a suitable lens and could buy a camera without a lens (which is not likely) it would cost a good deal to adapt it properly. You can do nothing to stop the Press from using your grouping; perhaps some day you will be glad to have a chance of doing the same.

M. E. J.—Under the Copyright Act you can demand delivery of all the copies of the book or other publication containing the photographs of yours, the copyright in which has been infringed. You are also entitled to damages, in which case, as no doubt your solicitor advises you, it is necessary to show the amount of the damage which you have sustained. Usually in such cases, where photographs have been produced without deliberate intention to infringe, photographers are ready to allow the sale of the publications to proceed providing a reproduction fee is paid in respect of each of, say, double the customary amount. As the minimum now for many reproductions is about 15s., we should think the people who have infringed your work would be very glad to settle the matter at 30s. apiece.

O. G.—(1) We certainly think you could make up with half the quantity of water and develop in about 10 minutes. (2) Bromide slows the developer considerably, best not to use more than is necessary to keep the negatives free from fog. An acid amidol developer needs very much less bromide for this purpose than other developing formulæ. (3) If the backing consists of an opaque pigment we think you may take it that it is inert in the developer, but if it is a dye, which usually means a transparent backing, the dye may have an effect on the developer, as has been recently discovered in connection with desensitising. But the effect is probably to make the developer slower or more rapid in action. (4) Cut films are liable to float about in an ordinary developing dish. One way of keeping them under the solution is to arrange a few dabs of plasticine at the bottom of the dish and gently press each film by means of a clean glass plate (not the fingers on to a little disc of the plasticine before flowing on the developer. (5) 10 ozs. of developer ought to be ample for treatment of six 3½ × 2½ films.

S. C.—The following method of waterproofing prints is said to be very good, but we have never tried it. After hardening, the prints should be dried, and then well sized, or floated upon a 25 per cent. solution of warm gelatine, and again dried. They are then varnished with the following mixture:—

Mastic	1½ oz.
Oil of lavender	¼ oz.
Alcohol	5 ozs.
Benzine	4 ozs.

This should be allowed to stand eight days, then decanted and used. This is a suitable finish for photographs to be framed up without a covering glass. You do not say what kind of prints are to be treated, or for what purpose they are required. Probably the following more simple print varnish would serve the purpose:—

Borax	150 grs.
Pale yellow shellac	300 grs.
Soda carbonate	50 grs.
Glycerine	150 minims.
Water	5 ozs.

Boil, cool, and add 5 ozs. of alcohol. Add pumice powder or whiting to throw down the lac wax, shake up, allow to stand a few days, and filter.

J. E. D.—(1) It is very difficult to give any idea of prices without knowing the class of trade you do; that is to say, what your customers can afford to pay On the basis you give we think that you should charge at least £2 2s. per dozen for the groups. It is to be remembered that out of this sum you have to pay rent, rates and taxes, wear and tear of apparatus, and your own living expenses. One shilling per hour is far too little to charge for your time; besides you spent more than half an hour on this job if you take into consideration developing, fixing and washing the negatives, packing and posting them to the trade house, and again delivering to the customer. (2) We believe that you can get an account book which might answer your purpose from Messrs. Marion and Co., 3, Soho Square, London, W.1, and we think that Messrs. Kodak, Kingsway, London, W.C.2, can supply you with a card system, which is what most photographers use. (3) As you do not appear to have any idea of book-keeping in general it would be a good plan for you to get (through your bookseller) "Munro's Elementary Book-keeping," published by Effingham Wilson, London; the pre-war price was one shilling. This will give you a clear idea as to starting a set of books.

Contents.

SUMMARY

Mr. E. J. Bedford describes the results of carefully conducted experiments made with the object of determining the best lens separation in the stereoscopic photography of small objects on a large scale in respect to the preservation of natural perspective when viewed in the stereoscope. (P. 367.)

In the third chapter on the H. and D. doctrine the effect of development on a plate having (through correct exposure) the density ratios in the correct relation is considered. It is shown that at one given point in development the contrast is equal to that of the subject and is expressed numerically by the value known as gamma. (P. 372.)

The second and concluding part of MM. Lumière and Seyewetz's contribution dealing with desensitisers is given this week (P. 370), also some editorial comments on the investigations. (P. 366.)

In much of the enterprise which is being shown as regards lighting and finishing of portrait photographs there is the tendency to neglect the most important quality, namely, likeness. (P. 366.)

Even in the case of the small cameras, now so popular, there is a limit to the depth of field, neglect of which is responsible for out-of-focus results, as is also accidental shifting of the focussing scale as a whole. (P. 365.)

An amended list of judges who are to act at the Royal Photographic Society's forthcoming exhibition, along with a rule concerning the sizes of mounts, will be found on page 378.

Formulæ and apparatus for the correction of aerial photographs which have been made with the lens axis in a non-vertical position are contained in a recent patent specification. (P. 375.)

A correspondent draws attention to a circular sent out by the Central Districts Branch of the London Master Printers' Association explaining the several varieties of picture and other postcards. (P. 379.)

Actual stereoscopic photographs were used by Professor C. Piazzi Smyth to illustrate his work, "Teneriffe, an Astronomer's Experiment," published in 1858. Some particulars of this unique publication will be found on page 365.

A method of eliminating troubles met with when using the developing tank in hot weather is described in our correspondence columns. (P. 379.)

Qualified medical practitioners who undertake X-ray work are now known as Radiologists, and qualified non-medical workers as Radiographers. (P. 380.)

EX CATHEDRA.

Focussing Small Cameras by Scale. Many users of small cameras fitted with large-aperture anastigmats can give abundant instances of unsharp negatives through error in estimating the distance between the camera and the subject. We are often too much in the habit of associating short-focus lenses such as are used upon these cameras with immense depth of field, and it should be pointed out that there is a limit to depth when very near objects are being photographed. Within ten or twelve feet the distance to a foot should be very carefully measured either by pacing the distance out, or by the help of a distance gauge, an necessory by the way. That used to be far more in evidence than now. Another cause of unsharp negatives with small cameras is that the focussing scale does not exactly fit the lens when distances beyond the infinity point are required. Focussing scales for many cameras are all marked the same, and though they may give quite a sharp image at infinity with all lenses, when nearer objects are being focussed the lens and the scale may no longer be in exact unison. On one camera that we recently examined the lens gave perfect definition at infinity, while an object carefully measured eight feet away was decidedly unsharp when the scale was set at that distance. Users of small cameras frequently make the mistake of misjudging the infinity distance and setting the scale for a slightly nearer point than is actually required. In practice it is surprising what a number of pictures may be taken with the lens at infinity, even with large-aperture anastigmats.

* * *

Stereoscopic Publishing in 1858. By the kindness of our old friend, Mr. Thomas Bolas, there has recently come into our possession a copy of the rare work which we happened to mention some weeks ago in writing of the early literature of photography which is to be found described and priced in the "Bibliotheca Chemico Mathematica" issued by Messrs. Sotheran. This is the volume "Teneriffe, an Astronomer's Experiment," by C. Piazzi Smyth, published by Lovell Reeve, Henrietta Street, Covent Garden, in 1858. It is a work describing the mission undertaken in 1856 by Piazzi Smyth for the Admiralty for the purpose of ascertaining to what extent astronomical observations could be improved by mounting the telescope at a great height. Mr. Smyth, therefore, proceeded to the Canary Islands, where observations at over 10,000 feet above the sea level were carried out. The volume, however, is not altogether a technical account of this scientific work, but a story of personal experiences in the mountains of the Canaries; and its chief interest from the historical photographic standpoint is its inclusion of a number of actual stereoscopic photographs representing scenes in Teneriffe. We think that there is no doubt that these photographs represent the first known use of stereoscopic photography in

the illustration of books. Under each print it is pointed out that they were made by A. J. Melhuish, under the superintendence of James Glaisher, F.R.S. The prints are, of course, by the early albumen process, and it speaks well for the permanence of the sometimes despised silver processes that, although there is some marked yellowing of the high-lights, there is very little evidence of actual fading of the image. In fact, many of the prints, we should say, are practically as vigorous as when they were made.

* * *

Likeness First. The young photographer who is possessed of a certain amount of artistic training and instinct is apt in his strivings after effects of lighting and composition to overlook that aspect of portraiture which is foremost in the minds of his customers, the likeness to the original. A couple of generations ago a photographic or even a painted portrait was commonly called a likeness, and it is a likeness that nearly all sitters, except society beauties, hope to get when they visit a studio. To this end the photographer should be chary in the use of unusual lightings or poses and avoid excessive retouching. In the finishing of enlargements there is great danger of losing the likeness by attempting to idealise the sitter, some very clever workers making this error. At the same time it is desirable to make the best of our subject, but not to bore him. Some of the best portraits have been secured when the sitter has relaxed after an exposure and has been caught with a natural expression which was previously absent. There has lately been a fashion of talking to the sitter while the exposure is made, but it must be sensible talk and not obvious cackle, such as we have sometimes heard.

NEW WORK ON DESENSITISERS.

The communication on desensitisers by MM. Lumière and Seyewetz, the concluding portion of which appears in our present issue, is one which will enable a clearer perspective of the subject to be obtained than has been possible hitherto. It places before those whose knowledge of languages does not extend beyond the "King's English" the first lucid account of qualitative and quantitative experiments with various substances, more or less well known to photographers, which appeared, from theoretical considerations, to be likely to act as desensitisers. It is quite appropriate that these workers should have taken up the investigation of this matter, for, as we have pointed out before, it was whilst probing results which they had obtained many years ago, that Lüppo-Cramer came across the germ idea which eventually led him to phenosafranine. With characteristic alacrity and thoroughness MM. Lumière and Seyewetz have returned to the subject, and have continued the research for the mutual benefit of the theorist and the practical worker.

The theorist might perhaps be disposed, on the first reading of the communication, to criticise the methods which were used in the testing of the ordinary, as distinct from the panchromatic, plates; it cannot be denied, however, that the tests applied, duplicated as nearly as possible, the actual conditions under which the practical worker would use desensitisers. Further, it is evident that these rapid practical tests expedited the progress of the research. Surveying the dyes which were already known to act as desensitisers, a programme was mapped out which had for its main object, we imagine, the elucidation of the theory of desensitisation. The photographer who is acquainted with the chemistry of dyes will appreciate the difficulties which had to be surmounted in the preparation, in pure form, of those likely dyes and intermediates which, as the authors say, are not obtainable commercially, and will congratulate our contributors on their achievements in preparing these bodies. Having, in one way or another, procured their products, they proceeded to separate them roughly into two well-defined classes. The majority of the substances proved to be useless as desensitisers in spite of the fact that they were constitutionally related to those which, by reason of their positive action, were considered worthy of further investigation. Quite early in the work, therefore, and employing only comparatively rough tests, they were able to conclude that desensitisation power was not concomitant with a certain arrangement of the various groups of atoms in the compounds which they were using. By comparing the constitutional formulæ of neutral violet and neutral red, for example, this conclusion will be at once justified. As stated in the text, the accepted formula for neutral violet may not be the correct one, but it is interesting to note in this connection that the introduction of a methyl group (CH_3) imparts an activity suggestive of, but much more pronounced than, that which results from the introduction of the same group into the well-known developer para-amidophenol, giving monomet.

Having narrowed down the selection of dyes, etc., the next part of the research—and, in our opinion, the most important part—was undertaken. It constituted an attempt, on somewhat different lines from those which have been used by Lüppo-Cramer to give a numerical value to the desensitising effect to any treatment. In order to make the matter clearer to the general reader we might perhaps indicate in non-technical language an equivalent of their procedure. It will simplify things if we assume that a strip colour chart of the spectrum of daylight is the test object, and that it is placed in the ordinary way on an easel in front of the copying camera. If in copying this spectrum chart, average daylight being the illuminant, a "pan" plate be used in the camera, and if the plate is equally sensitive to all colours, it is easy to see that the negative obtained will be a perfectly uniform grey strip. If the plate is less sensitive to some colours than to others, the particular portions of the negative representing the colours to which the plate is relatively less sensitive will be thinner or less opaque than the rest of the strip. By measuring just how much thinner the image is in these areas some idea of the relative sensitiveness of the plate to the particular colour can be obtained. A very simple addition to the outfit, however, will enable us to get a negative of the strip which shows automatically the relative sensitiveness of the plate for any part of the colour chart. All that is necessary is the placing in front of the plate in the dark slide of a device (wedge) which cuts off no light along one edge of the image and has a gradually increasing light-stopping power across its width. Assuming that the light-arresting material in the wedge stops all colours with equal facility, *i.e.*, exhibits no selective absorption, it is clear that any negative of the spectrum chart taken behind such wedge will show a deposit of silver at a greater distance from the edge of the image which received the maximum exposure, the more sensitive to that particular colour is the particular plate in use. The heights of the image from the most exposed edge thereof are thus a measure of the sensitiveness of the plate. Although the photographic investigator does not employ such "studio" methods, he works on exactly the same principle, and by tracing a line along the extinction boundary of the negative he gets such a curve as that given for example on page 370 this week. Again, by ascertaining the relative exposures which have to be given to two plates in order that the heights of the negative

image representing say, the red portion of the spectrum chart, shall be equal, the relative red sensitiveness of the two plates can be obtained and expressed numerically. A combination of both these methods has been successfully used by the authors of the communication enabling them to give exact information of first-rate importance. It would be well if all future work on desensitisation were thus quantitatively carried out—giving the specialist in each branch of photography just the information he desires, whether it be in reference to the illumination of his dark room or to the selective depression of colour sensitiveness of his sensitive materials before use. It is conceivable that selective desensitisation might obviate the necessity of a yellow screen in orthochromatic photography.

Turning now to the results and conclusions of MM. Lumière and Seyewetz, one is struck by the fact that the efficient desensitisers are mild "oxidising" compounds, a circumstance which lends support to the recently published assertion of Lüppo-Cramer that desensitisation is an oxidation phenomenon. One cannot interpret this expression in the usual chemical sense, for the restoration of sensitiveness consequent on washing out the desensitiser indicates that no permanent modification of the emulsion results from treatment with the desensitiser. To adopt similitude, one may regard desensitisation as the addition to the gelatine of a substance which just satisfies the appetite which the gelatine normally has for the "something" which is liberated by light action from the sensitive salt. Further, it might be suggested that this satisfying of the appetite does not result from a digestive process (which could be looked upon as the equivalent of a chemical reaction between desensitiser and gelatine), but rather from the mere "tasting" of the desensitiser, removal of which leaves an unimpaired appetite.

Several questions will no doubt suggest themselves to the interested reader, the correct answering of which would advance our knowledge of the whole subject of sensitisation. Such questions for example as:—Is the depression of sensitiveness induced by a given desensitiser applied in a definite way a constant factor of the initial sensitiveness, or is the residual sensitiveness remaining after treatment of the same order of magnitude no matter what was the initial sensitiveness of the emulsion? Does desensitisation reduce the sensitiveness to that of an unripened emulsion composed of the same materials, or to that of the same sensitive salt emulsified in a non-reducing carrier such as collodion? Is a given desensitiser active in the same regions of the spectrum for collodion colour-sensitised plates as for colour-sensitised gelatine plates?

These and similar questions can only be answered by the acquisition of information of a quantitative nature, and photographic science is indebted to MM. Lumière and Seyewetz for a description of their methods of working. The practical photographer is indebted to them for specific information on several points, amongst which must be mentioned that relating to the choice of desensitisers for bromide paper. On behalf of photographers in general, therefore, we express the hope that the authors will continue their work and give us the benefit of their further results, results which may materially enhance the value of our art in its application for the exact determination of the magnitude of phenomena with which the physicist, chemist, and scientist in general concern themselves.

STEREOSCOPIC LENS SEPARATION FOR NEAR OBJECTS.

The lack of practical information concerning the stereoscopic representation of near objects probably arises from the fact that until comparatively recent times no work, or, at least, very little, had been attempted in this direction.

During the past few years, however, many nature photographers have turned their attention to securing stereoscopic records of natural history subjects, accompanied, as they are, by faithful presentments of form, texture and even colour when required. The question arises, therefore, what are the best methods to employ in order to secure the most accurate results, and one point of considerable importance is, what is the best lens separation to use when taking near objects. This article is an endeavour to assist in the solution of the problem.

For the present purpose the term "near objects" may be taken to mean those photographed natural size, and may include also those represented on a scale of half full size, and small specimens enlarged to 12 diameters or more.

The writer recently carried out some experiments with the view of arriving at some practical data to work on, and the results of some of these experiments will follow. The point specially borne in mind was to determine, by practical methods, the best separation of the lens centres, in order to obtain *natural* as opposed to *exaggerated* relief. The point at issue does not seem to have been considered by the makers of stereo. apparatus, no commercial cameras on the market allowing for the small separation necessary for these near objects.

The pair of lenses are usually fitted to work at a fixed separation of 3¼ inches, and in the small number of cases where a variable separation is provided, it is arranged to work between the limits of 2¾ ins. and 3½ ins. or 3¾ ins. We have been told that this separation of 3¼ ins. is for the purpose of giving slightly exaggerated relief.

But why should we have this exaggerated relief when the whole process of stereo. photography is to present objects as seen in nature? The fact is, exaggeration has become so universal that when it is absent the representation is criticised as flat.

The average separation of the eyes being about 2½ ins. or slightly more it seems reasonable to argue that when photographing the average subject, the separation of the lenses should agree with the separation of the eyes. (We are not dealing now with exceptional cases either of very near objects or of very distant ones, e.g., the moon.) As a matter of fact, the more distant parts of an ordinary scene show very little relief to the eyes of an observer, and consequently should not be expected to do so in a stereograph.

The writer's experiments have been carried out with particular reference to the correct stereoscopic representations of comparatively small natural history specimens, such as entomological or botanical subjects photographed full size, where truth of effect is an important factor.

There are a good many naturalists engaged upon this class of work at the present day, hence the importance of a correct solution.

The "British Journal of Photography" for December 12, 1919, p. 725, contained a formula given by Mr. C. E. Benham in reply to a correspondent, and this has been reprinted in the 1921 "B.J. Almanac," p. 351. He sums up his remarks

as follows:—"Practically, therefore, a quarter of the distance of lens from object will give the separation distance for objects at close range."

There is not the slightest doubt that greatly exaggerated relief will be obtained if this formula is followed. The substitution of 1-20th for ¼th of the distance will give results more akin to those perceived by the eyes of an observer. The distance of distinct vision he gives as 12 ins., and this may be adopted as a standard. It would be, also, the distance of object from lens when photographing it full size, with a lens of 6 ins. equivalent focus.

In the table below the separations given by Mr. Benham are shown in column A, while those given by Mr. T. J. Ward are in column B. Those recommended by the writer are given under C, and as will be seen, are less than a quarter of those given under A.

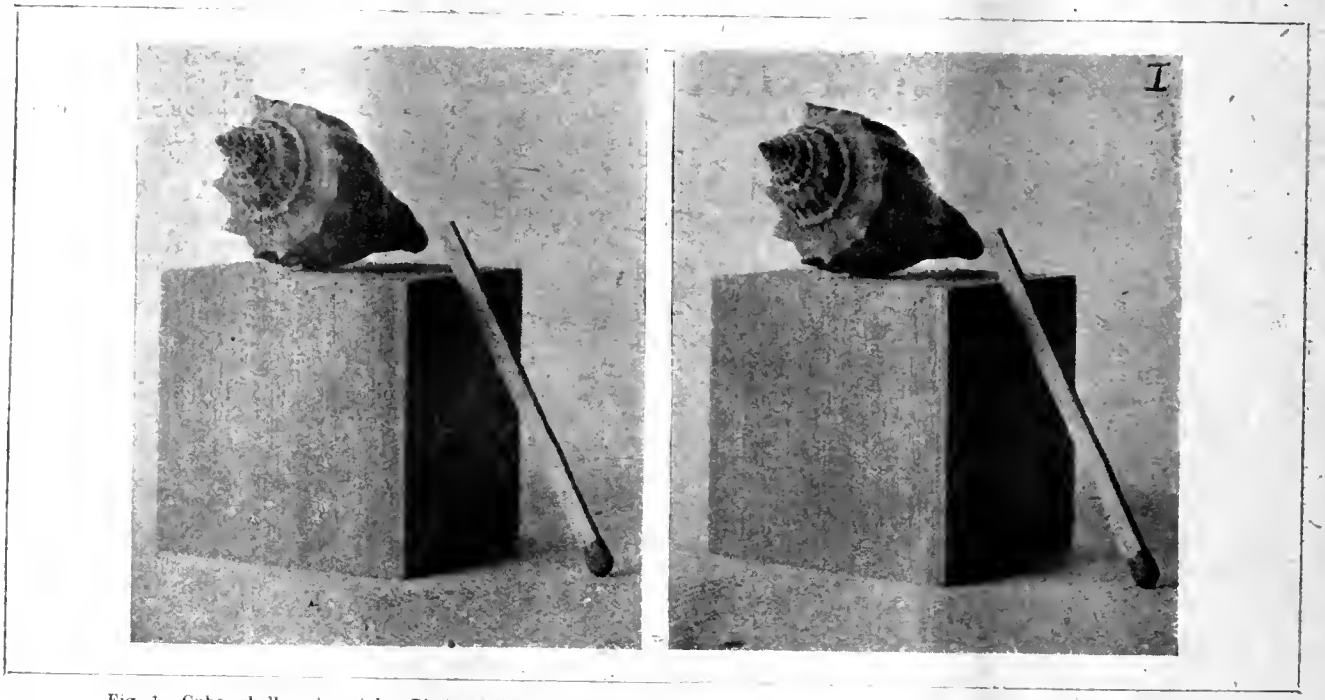

Fig. 1.—Cube, shell and match. Photographed same size. Lens focus, 5¾ in.; stop, f/22 (nominal); separation, ⅝ in.

For easy reference the fractions are given in 32nds of an inch.

Distance of object from lens.	Separation required (inches or part of an inch).		
	A.	B.	C.
12 ins.	2 24/32	1 8/32	20/32
10 ins.	2 9/32	1 1/32	16/32
8 ins.	1 27/32	27/32	13/32
6 ins.	1 12/32	20/32	10/32

When the object is still nearer the lens the separation required may be found by means of a proportional sum either graphically or otherwise.

Using the 6 ins. focus lens for other proportions of images to original the following distances may be taken:—

Scale	×½	×¼	×⅛	× less than ⅛
Separation	1 in.	1½ in.	2 ins.	2¼ ins.—2¾ ins.

It is not advisable to exceed a lens separation of 2¾ ins. for any scene which embraces objects varying in distance from 10 or 12 ft. to infinity. Unfortunately, theory and practice do not always agree, and when they differ it is safer to adopt procedure which has been proved by practical experiments to be correct. Illustrations are shown in support of the separations given under C, and to show the effect of those given under B and A.

To the practical worker who may not have given the matter serious consideration before, probably the first question will be:—How are the small separations given under C to be arranged for? In reply, it may be stated at once that they cannot be satisfactorily used, when it is necessary to give one exposure, with the pair of lenses, as would be required in the case of a subject where movement was possible. In such cases the best thing to do is to take the photograph on a scale small enough to allow for the required separation, and if a larger image is required, to obtain it either by making an enlarged negative or a direct transparency in the camera.

In the great majority of cases, however, the subjects will be such as allow of two successive exposures.

When the required separation is very small a separate plate must be used for each exposure, and a quarter-plate or 3½ in. × 2½ in. camera will serve the purpose very well; all that is necessary being to slide it bodily to right (or left) for the required separation, between the two exposures. Another method is to rotate the object, but this will not be satisfactory unless the angle of light can be altered also to give identical light and shade for each position. If a half-plate camera is employed, the dark slide can be fitted with a carrier to take a quarter plate, and the two exposures may be obtained as with the quarter-plate camera.

Another convenient arrangement for a half-plate or post-card-size camera is to fit a sliding front long enough to allow of a movement of about 1¼ ins. each way without letting in light at the sides of camera front. The sliding front is fitted with a flange to carry one lens and a scale provided with zero mark in the centre, so that the lens may be shifted to right and left successively, the camera remaining fixed. In this case it will be necessary to inspect the image on the screen before each exposure, to see that it comes on the plate, and in order to secure this, it may be necessary to rotate the camera on its axis slightly. As this would reduce the separation somewhat, allowance for it should be made when shifting the lens.

In order to prevent mistakes when the two exposures are made on separate plates, it is well to carry out the work under certain rules. Expose for the left view first, and let this always bear an odd number—1, 3, etc. The drill sergeant's instruction, "left, right, left, right," may help to fix this on the mind. Let the right view be on a plate numbered 2, 4, etc., and if the plates before development are marked L or R with a lead pencil it will prevent mistakes. Bear in mind

that no transposition of prints will be necessary in this case, the negatives marked L will give the left-hand print.

Presuming a half-plate or other size stereo camera is used to obtain the two images on one plate, the probability is that the septum will not extend far enough to allow of an extension of 12 ins. If it will not the best thing is to remove it temporarily, and to fit a black card into the back of camera as near focussing screen as possible to cover up half the space. The two images should be inspected on the ground glass in turn by sliding the front with the one lens, shifting the card, of course, to allow each image to be seen. When one exposure has been made the slide should be closed and withdrawn, the card shifted to the reverse side of camera, the slide re-inserted, and the second exposure made. Always expose the *left* view first, the card, of course, being always on the right hand to start with. The card in the back of camera, where it can be seen, is safer than one in the dark slide, which may or may not work. An alternative method is to make use of a dark-tinted card cut the required length and width to fit roughly, and stand upright down the centre of the bellows and reaching from the lens board to focussing screen. In this case, if the two images are inspected on the screen, and the lens positions noted before the first exposure is made, there will be no necessity to withdraw the slide between the two exposures.

In the opinion of the writer the most suitable lenses for the

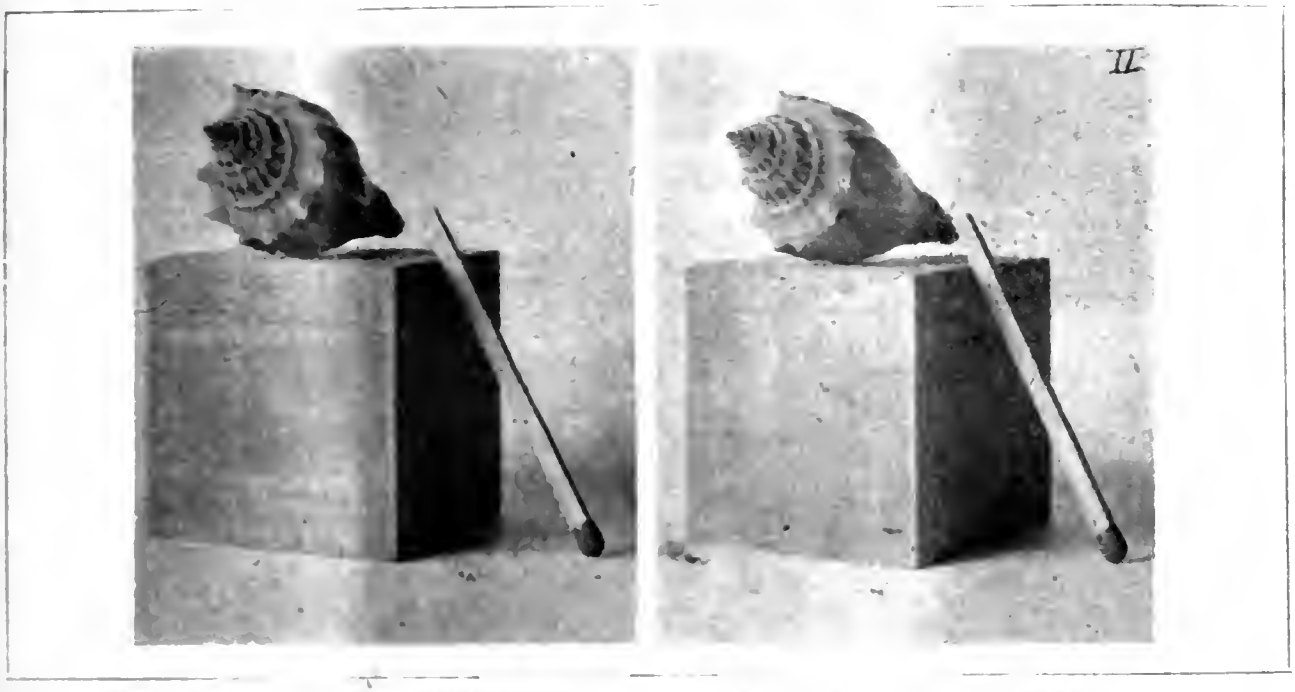

Fig. 2.—Cube, shell and match. Photographed same size. Lens focus 5¼ in.; stop, f 22 (nominal); separation, 1¾ in.

Fig. 3. Cube, shell and match. Photographed same size. Lens focus 5¼ in.; stop, f 22 (nominal); separation, 2¾ in.

majority of stereo subjects are those with an equivalent focus of from 5 to 6 ins. One word with reference to the separation of centres for the mounted prints. Generally, it will be found that a distance equal to the separation of the eyes, i.e., from 2¼-2⅝ ins. will be best. In no case should the separation exceed 2¾ ins. if an easy coalescence of the two images is desired. This will suit any kind of stereoscope in general use. The eye strain produced by trying to combine a wider separation is not conducive to comfortable viewing of prints.

The provision of suitably mounted lenses does not appear to have received the attention it deserves from opticians. The mounts and flanges of lenses for stereo work might often be reduced in size to allow of a smaller separation between their centres being more easily obtained. It ought to be possible to obtain a separation of 1½ ins. between a pair of 6-in focus lenses, working at about *f*/6.5, and a larger aperture than this is not desirable, nor is it often necessary or advantageous to employ one as large as this in stereo work on account of the want of depth of field.

The Illustrations.

Out of a number of experiments the following have been selected to show the effects produced by the three different separations of lenses. Each subject was taken full size, and in each case the distance of object from lens was 11½ ins. All three were taken with a lens of 5¾-in. equivalent focus at *f*/22 aperture (nominal). In the case of fig. 1, the lens separation was ⅝ in.; in that of fig. 2, 1¼ ins.; and in that of fig. 3, 2⅜ ins.

The edges of cube were 1½ ins. long, the longest axis of the shell was 2 ins.

In these examples notice particularly the apparent greater width of the face of cube in shadow in fig. 3 (the widest separation); also that the match does not appear to lie in a vertical plane as it should do, and as it does in fig. 1.

The writer hopes that these examples, from a large number of experiments which he has carried out, may be of interest and practical use to those workers who are striving after the most accurate results in the fascinating branch of stereoscopic nature photography.

E. J. Bedford.

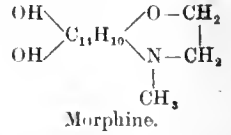
EXPERIMENTS ON DESENSITISERS.

(*Concluded from page* 354.)

Non-Coloured Organic Compounds.

We have examined a great many organic compounds of very different properties, both oxidising and reducing substances. None of the oxidising substances, among which is quinone (the starting point of the safranines), appeared to possess any desensitising action.

Organic compounds having reducing properties are limited to developing substances containing amino groups, and their desensitising properties have been pointed out by Lüppo-Cramer in the case of diamidophenol, diamido-resorcin, triamidophenol, triamido-benzene, triamido-toluene, and paraphenylene-diamine. We have studied the action of other nitrogen organic substances, and particularly a large number of alkaloids. Only one of these has been found to exhibit desensitising properties comparable with those of diamidophenol hydrochloride. This is *apomorphine hydrochloride*, which is regarded as a product of the dehydration of morphine.



Morphine.

The solution, which has oxidised in the air and become of blue colour, is more active than that freshly prepared.[3]

Desensitising Action of Mineral Substances.

Among the most varied mineral substances, both reducers and oxidisers, which we have examined, none appears possessed of desensitising properties of special interest.

Many oxidising substances, such as copper salt, alkaline bichromates, chlorine and bromine water and iodine solution, greatly reduce the sensitiveness of unexposed gelatine emulsion, but equally attack the latent image, and, therefore, are useless in practice.

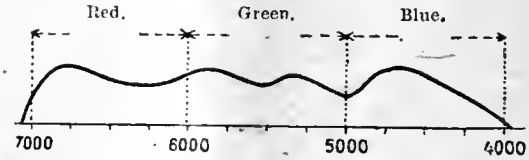
Neutral chromates, and especially neutral potassium chromate in 2 per cent. solution, are the only mineral substances which we have found of any value as desensitisers. Their action is somewhat less than that of diamidophenol, but they have the advantage of giving stable solutions.

(3) The constitution which is generally attributed to apomorphine does not seem in accordance with its reducing properties, and particularly its property of developing the latent image on addition of alkaline sulphite and carbonate to a solution of its hydrochloride.

Desensitising of Colour-Sensitive Plates.

The experiments already described were all made with ultra-rapid ordinary plates (Lumière Violet Label), and the results therefore relate chiefly to the reduction of sensitiveness to blue and violet rays. We have also examined the most active of the desensitisers in respect to their behaviour with panchromatic plates in comparison with safranine, which, as has been shown by Lüppo-Cramer, desensitises emulsion for all parts of the spectrum.

For this purpose we used panchromatic plates (Lumière Chroma VR plates), the colour-sensitiveness of which extends a little beyond 700. The curve of colour-sensitiveness of this plate is as shown in the drawing.



These plates were exposed in the spectroscopic camera and then immersed, in the dark, for one minute in the following desensitising solutions:—

Phenosafranine, 1: 2,000 solution; also in the other safranines mentioned above as giving results comparable with phenosafranine.

Toluylene red, 1: 1,000 solution; immersion for 4 minutes.

Aurantia (ammonium salt), 1: 1,000 solution.

Pieric acid, 1 per cent. solution.

Indian yellow, 2 per 1,000 solution.

Chrysoidine, 1: 2,000 solution.

Diamidophenol, 1 per cent. solution.

Apomorphine hydrochloride, 1 per 1,000 solution.

Neutral potass chromate, 2 per cent. solution.

After immersion in the desensitiser these plates were developed for 1½ minutes in the dark with normal diamidophenol developer, and then for 2 at a distance of from 4 ft. to 18 ins. from a 16 c.p. incandescent bulb screened with tartrazine paper and yielding a very bright light. During this development plates were examined four times (for 3 seconds each time) by transmitted light.

Under these conditions the plates treated with the various safranines already mentioned, and also those treated with toluylene and aurantia (ammonium salt), gave images having

only very slight fog, whilst all the others were strongly fogged.

If this intense light-source be replaced by weaker illumination, *e.g.*, by a small Pigeon lamp, with the maximum height of flame adjusted so that the lamp does not smoke, and with a bright yellow screen round the lamp (without taking any precaution to prevent escape of diffused white light above the screen), by developing under the same conditions as already mentioned and at a distance of 0.50 metres from the light-source, the results are the same as those already described. *Only the safranines, toluylene red and aurantia* gave images which were not fogged. None of the other substances could be employed for desensitising panchromatic plates.

Relative Desensitising Action.

In order to measure the relative reduction of sensitiveness of panchromatic plates for the different parts of the spectrum we made a comparison scale by impressing a spectrum on a series of Lumière Chroma panchromatic plates with exposures which were relatively 1, 2, 3, 4, 5, etc. These plates were treated in a normal diamidophenol developer. Exposures were made in the spectroscopic camera under the same conditions on panchromatic plates of the same emulsion after immersion for 1 minute in the respective desensitising solutions.

The plates were well drained and placed whilst wet in the holder of the spectrograph and exposed for a time 60 times greater than the plate of the preceding series which received the longest exposure. The resulting spectra were developed under the same conditions as those obtained on plates the colour-sensitiveness curve of which has been shown above.

The reduction of sensitiveness in comparison with the untreated plates was thus ascertained, the results being as follows:—

Desensitiser.	Time of Immersion.	Sensitiveness after treatment, compared with original sensitiveness.
	Minutes.	
Phenosafranine, 1/2000.	1	1/750 to 1/800 for blue, maximum about 425. Sensitiveness destroyed for all other parts of spectrum.
Toluylene red = 1/1000 Eurodine.	4	1/400 for blue; 1/3,000 to 1/4,000 for other rays.
Apomorphine hydrochloride, 1/1000.	1	About 1/200 for blue. Sensitiveness to other rays destroyed, except to red, for which rays it was about 1/10,000. Slight chemical fog.
Aurantia (ammonium salt), 1/1000	1	1/750 to 1/180 for blue, maximum at about 425; 1/400 for other rays.
Picric acid, 1 %	1	About 1/200 for blue, maximum about 485; 1/120 for blue, about 475; 1/200 for other rays.
Indian yellow, 1%	1	About 1/30 in blue-green, blue and violet; almost without action for other rays.
Chrysoidine, 1/1000	1	Practically uniform effect (about 1/100) throughout spectrum.
Potass-chromate, neutral, 2%	1	Practically uniform effect (about 1/40) throughout spectrum.

NOTE.—These tests could not be made with diamido-phenol, since the long period of exposure required by the wet plate allows the oxidation products to stain the plate, and every trace of the image is destroyed.

The experiments show that the safranines are the best desensitising for the whole spectrum. Nevertheless, desensitising is not as complete for the blue as for rays of the other parts of the spectrum.

Toluylene red acts on the blue almost like safranine, but leaves a slight sensitiveness for the other parts of the spectrum.

Oxidised apomorphine behaves similarly to the safranines for all parts of the spectrum with the exception of blue. In this latter region the desensitising action is one-quarter that of the safranines. It is to be noted that the use of apomorphine hydrochloride leaves a very slight residual sensitiveness to red and that there is slight chemical fog.

Aurantia (1 per thousand ammonium salt) shows desensitising action towards the blue equal to phenosafranine, but reduces the sensitiveness towards rays of other parts of the spectrum only to 1-400th.

Picric acid in 1 per cent. solution acts chiefly as a filter, and its action, which varies greatly with the concentration of the solution, is particularly marked as regards blue, for which rays its desensitising effect is greater than that of safranine but is negligible for other rays.

Indian yellow exerts a weak action, the sensitiveness to blue being reduced to about 1-50th; for other rays of the spectrum its action is extremely small.

Lastly, neutral potassium chromate acts uniformly as a desensitiser for all the rays of the spectrum, reducing the general sensitiveness to about 1-40th.

Rationale of Desensitising by Safranine.

In considering the nature of the action which the safranine dyes exert on bromide emulsion, it may be thought that this action is simply that of a light-filter. This hypothesis obtains little support when it is observed that phenosafranine solutions transmit both red and violet, yet desensitise plates for both these rays. Moreover, the use of a dark-room lamp, the safelight of which consists of a 1: 2,000 solution of phenosafranine, does not prevent the production of fog on plates, and particularly on panchromatic plates. Further, violet safranines are desensitisers of ordinary and panchromatic plates, as red safranines are, although the absorption spectra of the dyes are very different. It must, therefore, be concluded that the desensitising is not an entirely physical process. If plates which have been treated with phenosafranine are washed, it is found that the sensitiveness possessed by the plate before treatment slowly reappears as the dye is washed out and is completely restored when the dye has been completely removed.

These results are obtained, in the case of panchromatic plates, for all the rays of the spectrum.

It is therefore clear that the phenomena require for their explanation the assumption that the bromide emulsion forms an adsorption complex of much lower light-sensitiveness, and that this complex is gradually decomposed by water in the case of both ordinary and panchromatic plates.

Choice of Desensitisers.

It may be asked what is the best choice of a desensitiser for a given purpose among the many desensitising substances which have been mentioned.

Undoubtedly the safranines, and particularly phenosafranine, are the best desensitisers for general use with both high-speed ordinary and panchromatic plates. The drawback which these dyes possess as regards staining the fingers and requiring long washing for removal from the gelatine film may, however, cause others to be preferred on those numerous occasions when complete desensitising of red-sensitive emulsion is not required. Aurantia, the properties of which are very similar to those of safranine, does not suffer from these drawbacks.

Under conditions when it is not required to examine plates by transmitted light, as, for example, in the development of Autochromes, a 1 per cent. solution of picric acid, a 1: 2,000 solution of chrysoidine, or a 2 per cent. solution of neutral potassium chromate, may be employed as effectively as Aurantia. The preliminary treatment of the plate for half a minute in one of these solutions will allow, in the case of safranine or aurantia, of noting the appearance of the image at a distance of 5 ft. from a candle or Pigeon lamp, and of watching the progress of development at frequent intervals. At the same time is is advisable to avoid unnecessary continuous exposure of the plate to the light.

These last mentioned desensitisers, which are free from staining action on paper, whilst safranine cannot be completely removed from paper, thus serve equally for desensitising bromide paper prior to development.

A. AND L. LUMIÈRE.
A. SEYEWETZ.

THE H. AND D. DOCTRINE.

In the preceding chapter the law of the production of a theoretically perfect negative has been considered in reference first to the time of exposure. That law is that the difference between any two of a series of densities is *proportional* to the difference between the logs of the producing exposures.

Correct exposure thus lays the basis for the making of the theoretically perfect negative, in which the difference between each pair of a series of densities is *equal* to the difference between the logs of the corresponding exposures.

By experiment it is found that this exposure law operates only when a plate is exposed for a longer time than will give some kind of a negative; also, that the law ceases to operate when the plate is exposed for longer than a certain time.

By plotting the densities against the log exposures the range of exposures over which the plate behaves in accordance with the law is shown by the straight line part of the resulting curve.

This straight line portion shows the latitude of the plate and also—when the range of light-intensities in the subject is approximately known—the latitude in exposure.

But correct exposure, as shown by the straight line part of the curve, is only one stage towards correct reproduction of the tones of the subject in negative form.

It shows that the differences between successive pairs of densities are equal to one another, *i.e.*, proportional but not necessarily equal to the difference between the logs of the corresponding exposures where these exposures proceed by a common factor.

Since, however, the whole series of densities are *proportionately* increased as development is continued, the common difference is similarly increased, and hence at a "correct" stage of development the negative corresponds with theoretical requirements.

Development may be carried short of or beyond this point as required by the subject or printing paper.

Consideration of development from this standpoint in the present chapter is concerned chiefly with the contrast or gamma of a negative, from which it will be seen that contrast in a negative is related, on the one hand, to the contrast in the subject, and, on the other hand, to the contrast properties of printing papers.

III.—DEVELOPMENT AND THE REPRODUCTION OF CONTRAST

Let us consider how far we have arrived at this stage towards realising the condition for a theoretically perfect negative, viz., that the light-intensities which its various parts transmit require to be in inverse proportion to those emitted by the corresponding parts of the subject.

But so far we have only seen that, provided a certain "correct" length of exposure be given, the densities (silver deposits) produced by the various light-intensities are in that logarithmic relation which we may most speedily visualise by remembering that as the light-intensities increase by a common *multiple* the densities receive an equal *addition*. Evidently this in itself does not fulfil the above condition. Correct exposure has determined simply a constant *difference* between two densities; but that difference may be smaller or larger than the difference between the corresponding log exposures. To borrow the image of the staircase in fig. 7, we have got each step the same height, but we have not done anything towards fixing what that height requires to be, or what means to take to make it the required height. In order to find our way to this next step it is clear that we must consider again the relation of density to opacity. Why? Well, we have got a series of densities in relatively correct relation to the exposures. We have now to modify them to such an extent that the opacities corresponding with them shall be in the correct relation, viz., proportional to the light-intensities in the subject. The densities are, so to speak, a half-way house on the road to the theoretically perfect negative.

Consider then again for a moment that illustration of density from which was seen its peculiar (logarithmic) effect on opacity. Adding one grass per unit area we reduced our traveller's power from 1-10th of its full strength to 1-100th of its full strength; or, the other way about, increased the opacity of the region from 10 to 100. Addition of another grass increased it to 1,000. The analogy correctly shows the relation of density to opacity. For each successive equal addition to density, the resulting opacity is the previous one multiplied by a factor, in this case 10; or, in general, as the densities increase by addition, opacities increase in multiple. An increase of 0.3 in density means a factor of 2, or doubling the opacity.

Pursue this relation of density to opacity just one step farther. We have seen that the effect of continued development on a series of densities is to increase them all, not by an equal addition to each, which is the law of their formation by successive multiples of such unit exposure as lies within the period of correct exposure, but proportionately (the Law of Constant Density-Ratios). It therefore follows that the relative opacities are enormously increased in this process. An example will make this clear.

Density.	Corresponding opacity.	Ratio of opacities.
1	10	1
2	100	10
3	1,000	100

Suppose now by longer development these densities are proportionately increased, say doubled. We then have:—

Density.	Corresponding opacity.	Ratio of opacities.
2	100	1
4	10,000	100
6	1,000,000	10,000

It will be seen that while the density ratios remain the same the opacity ratio has been increased a hundredfold. The above are impossible values in practice, but they present the question in the simplest form.

Now we can see the part played in the production of the theoretically perfect negative by this rapid growth of opacity during development. Suppose that light-intensities (from the subject) of 10, 100, 1,000 produce, first latently and then by development, the densities .5, 1.0, and 1.5, that is differing from each other by .5, whilst the log exposures differ by 1.0. We shall then have:—

Light-intensities	10	100	1,000
Densities, say	.5	1.0	1.5
Ratio of densities	1	2	3
Opacities	3.2	10	32
Ratio of opacities	1	3	10
Relative transparencies	1/1	1/3	1/10

Plainly this does not fulfil the condition of the theoretically perfect negative; the transmissions are not in inverse proportion to the light-intensities which produced them, but are in too small a ratio. For correct representation the transmissions should be:—

1/10	1/100	1/1,000
or 1/1	1/10	1/100

It is clear that in printing such a shortly developed negative long enough for full depth in the darkest tone (of the subject) the deposit representing the two others will let through too much light, *i.e.*, will print too dark, *i.e.*, the print *will* be flat.

In the case of the negative of three times the densities obtained by longer development we have, say:—

Light-intensities	10	100	1,000
Densities, say	2	4.0	6.0
Ratio of densities	1	2	3
Opacities	100	10,000	1,000,000
Ratio of opacities	1	100	10,000
Relative transparencies	1	1/100	1/10,000

Here we have departure from the theoretically perfect negative far in the opposite direction. The ratio of transmissions is enormously too great. In printing the darkest tone (of the subject) to full depth, the opacities of the other two are such that scarcely any impression would be obtained. An extreme example of a hard negative.

It is hardly necessary to point out that between these two times of development is one, and only one, which yields opacities of the required ratio 1:10:100, corresponding with transmissions of 1/1:1/10:1/100, in inverse proportions to the light-intensities from the original; that is to say, densities of 1, 2.0, 3.0, equal respectively to the logs of 10, 100, 1,000. That is the correct period of development, and we must now turn to see how this theoretically correct degree of development can be represented in figures: how it is related to the correct degree of contrast in the negative; how we arrive at an important property of a plate, its contrast-yielding property; and finally how the time of development to a required and specified degree of contrast can be calculated. We are, in short, proposing to become familiar with a characteristic of negatives and of plates which plays a leading part on the sensitometric stage—gamma.

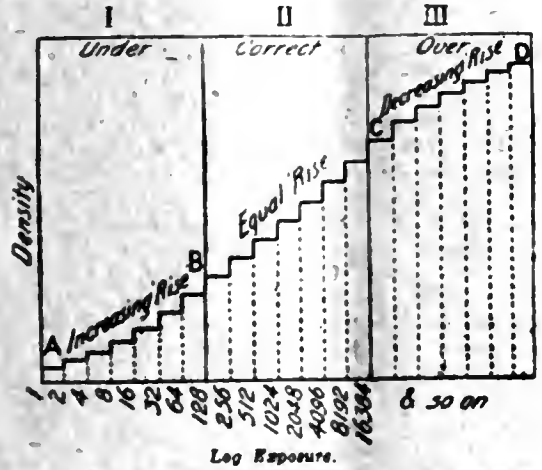


FIG. 7.—HOW DENSITY IS ADDED AS EXPOSURE IS MULTIPLIED.

In II. (correct exposure and correct development), increase in density at each step is equal to the increase in log exposure. In I. (under-exposure), addition of density is *greater* at each *equal* increase in log exposure. In III. (over-exposure), addition of density is smaller at each equal increase of log exposure. (Hurter and Driffield.)

Contrast.

We have seen that in a correctly exposed negative the differences between the densities are proportional to the differences between the logarithms of the exposures, and if the negative is developed to a certain "correct" degree the opacities are proportional to the exposures. But if the negative be developed less or more than this correct degree, that is to say, if the densities are all proportionately less or greater, the opacities are not in any simple relation either to the exposures or to the logarithms of exposures. For example:—

Exposure (E)	1,000	100	10
Log E.	3	2	1
Density (D), say	3	2	1
Opacity	1,000	100	10
Ratio of opacities	100	10	1

Here line 3 represents development to such a (correct) degree that the opacities corresponding with the resulting densities are proportional to the exposures. But trace the effect on the opacities of development to such degrees that the densities are all uniformly 25 per cent. less and 25 per cent. more; that is, are respectively .75 times and 1.25 times the values in line 3. We then have:—

Density	2.25	1.50	.75
Opacity	177.8	31.6	5.6
Ratio of opacities	32	5.6	1
Density	3.75	2.50	1.25
Opacity	5624	316.4	17.8
Ratio of opacities	316	18	1

It will thus be seen that when the densities are altered (as they are by development) in a very simple manner, the opacities alter in a manner which bears no simple relation either to the exposures or to the logarithms of the exposures.

One Way of Expressing Contrast.

The contrast of a negative is evidently the ratio of its opacities to the light-intensities from different parts of the subject in the case of a camera negative. If light-intensities of, say, 20 and 1, produce in a correctly exposed negative opacities of 20 and 1 (or 40 and 2; or 60 and 3) the contrast is obviously correct, whilst a negative of opacities 10 and 1 would be soft, and one of 50 and 1 would be hard. If we were concerned only in measuring the contrast of negatives which had been made it would be convenient enough to denote contrast as the ratio of the two ratios—opacities in the negative and light-intensities from the subject, *e.g.*, in the case of the correct negative from a 20 to 1 subject.

$$\frac{\frac{20}{1}}{\frac{20}{1}} = 1.$$

Similarly such a measure in the case of 10–1 and 50–1 negatives would be

$$\frac{\frac{10}{1}}{\frac{20}{1}} = \frac{1}{2} \text{ (a flat negative)},$$

$$\frac{\frac{50}{1}}{\frac{20}{1}} = 2\frac{1}{2} \text{ (a hard negative)}.$$

But, as will be seen directly, we require not only to measure contrast after we have got it, but also to calculate how long to develop in order to get such and such a degree of contrast; and for this latter purpose the irregularity (really the mathematical complexity) of the growth of opacities as development proceeds is a serious drawback to the use of opacities in the measurement of contrast. For this reason contrast is preferably expressed in another way in terms of density and log exposures; that is to say, the units employed in the production of the characteristic curve. Hurter and Driffield called this the "development factor," and denoted it by γ (gamma). It is now more usually known as gamma.

Gamma as the Measure of Contrast.

Gamma is the ratio of the density range in the negative to the range of the logarithms of the exposures producing those densities.

In setting down the range of density in a negative we are dealing with the physical stuff of which the image consists. Therefore, we specify the range by subtracting the lowest density from the highest; and similarly we specify the range

* The greater and lesser density values in preceding examples in this chapter are illustrative only. Round values have been chosen in order to avoid encumbering the tables with a mass of figures, but the examples correctly exhibit the effect of proportional increase of densities on the ratio of the corresponding opacities.

of log exposures by subtracting the lowest log exposure from the highest. Gamma is therefore:—

$$\text{gamma} = \frac{\text{difference of maximum and minimum densities of a given series}}{\text{difference of the logs of the respective exposures}}$$

or, in the language of the characteristic curve,

$$\text{gamma} = \frac{D_1 - D_2}{\log E_1 - \log E_2},$$

E_1 being the exposure which produced D_1, and E_2 the exposure which produced D_2. Thus gamma, as a measure of contrast, stands in somewhat the same relation to the ratio

$$\frac{\text{opacities of negative}}{\text{corresponding light-intensities from subject}}$$

as densities do to the corresponding opacities. Gamma also is a measure, not only of the intrinsic contrast (range of gradations) of a negative, but of the contrast relatively to that in the subject. A gamma of less than 1 indicates a contrast less than that of the subject: one of more than 1, a negative of greater contrast than the subject, always providing—and this applies to each and every value or calculation of gamma—*that the range of the subject is such that it can be recorded within the straight-line part of the curve of the plate, and is so recorded.*

If we calculate the densities, and from them, by the formula just given, the gammas of the negatives (correctly, over- and under-developed), representing a subject of light-intensities ranging from 20 to 1, we shall see the much smaller range of gamma values as compared with the values of

$$\frac{\text{ratio of opacities}}{\text{ratio of exposures}}$$

which represents the same facts in different terms.

Correct development.

Exposures	20	1
Log exposures	1.3	0
Opacities	20	1
Densities (log opacities)	1.3	0

$$\text{Gamma} = \frac{1.3-0}{1.3-0} = 1$$

Under-development.

Opacities	10	1
Densities	1	0

$$\text{Gamma} = \frac{1.0-0}{1.3-0} = \frac{1.0}{1.3} = .77$$

Over-development

Opacities	50	1
Densities	1.7	0

$$\text{Gamma} = \frac{1.7-0}{1.3-0} = \frac{1.7}{1.3} = 1.3$$

Since the range of light intensities in the great majority of subjects (interiors, open doorways, etc., are exceptions) *can* be recorded within the range of correct exposure of a plate (its latitude as previously defined), it follows that, if exposure has been correct, a high gamma necessarily signifies development to a degree yielding contrast considerably greater than that of the original subject On the other hand, a low gamma signifies development to a degree yielding contrast considerably less than that of the original subject.

Gamma and the Qualities of Negatives.

The student must not be misled into thinking that a high gamma necessarily represents what he calls a "contrasty" negative and a low gamma a flat negative. Such may, or may not, be the case, dependent on the range of contrast in the subject. Unfortunately, the terms we use for the contrast qualities of negatives are both loose and undescriptive. Perhaps when we speak of a "flat" negative we mean one in which the contrast is less than in the subject: by a "contrasty" negative we mean one the contrast of which is rather more than that of the subject; and by a "hard" negative, one the contrast of which is a good deal greater than that of the subject. But these terms are somewhat loosely applied, and I daresay many photographers use them to describe the intrinsic contrast of a negative (without reference to the subject). If we could agree to use the term "weak" for a negative which is flat because the subject was flat, and the term "strong" or "vigorous" for a negative which is of this character because the subject had a considerable range of contrast, it would be to the advantage of our vocabulary. But that is too much to expect, for the eye is not expert enough in judging contrast, particularly in negatives of great opacity such as result from maximum correct exposure of a plate of great latitude followed by development to the correct degree. Nevertheless, it must be borne in mind that a subject of small contrast and one of great contrast will respectively yield negatives, which, if correctly exposed and both developed to a gamma of 1, are both of the theoretically correct degree of contrast, though the one would be called flat and the other contrasty.

As regards negatives which have not been correctly exposed, that is to say correspond with the under-exposure or over-exposure part of the characteristic curve, the applicability of gamma as a measure of correct reproduction of contrast obviously breaks down. It is beyond the scope of these articles to consider to what approximate extent the gamma may be taken as a rough indication of the best development of negatives which are wrong at the start. Plainly, if the differences between two densities are not proportional to the differences between corresponding logs of exposures, no degree of development is correct, and therefore no value of gamma greater or less than 1 is a true measure of the degree to which the contrast of the subject has been increased or diminished in the negative. The most that can be said here is that under-exposure simulates the effect of a high gamma; and over-exposure that of a low gamma, which is only the statement in sensitometric language that an under-exposed plate yields harsh contrasts on continued development, whilst an over-exposed plate yields a flat negative unless very thoroughly developed. But in the absence of correct exposure, gamma as a measure of correct development must be regarded as of no significance.

Having thus obtained a conception of what gamma is and of the limits within which gamma is applicable, we can proceed to consider the simple way in which its value is indicated on the system of plotting densities against log exposures adopted for the production of the characteristic curve.

Gamma and the Characteristic Curve.

In the straight line part of the characteristic curve, as plotted in Fig. 9 and as diagrammatically shown in Fig. 8, each density differs from the preceding and succeeding one by the same amount. The slope of the curve, that is the angle it makes with the log exposure scale, is thus a measure of the rate at which densities increase by this repeated addition for each multiple of exposure. If by longer development the densities are all increased proportionately, say doubled, this equal difference between each is also doubled, and the rate of rise to a given density is doubled in the same way that a tradesman makes a given profit twice as quickly when the cost price and the selling price of his goods in regular demand are both doubled. Fig. 8 is a diagram which illustrates this steeper ascent of the straight-line part of the characteristic curve produced by longer development.

It is, therefore, clear that the angle made with the base line is related to the difference between the lowest and highest densities falling in the straight-line part of the curve; that is to say, is related to the contrast or steepness of gradation of the negative, relatively to the logs of the respective exposures.

This relation is expressed in an exceedingly simple way by means of a little geometry applied to the characteristic curve. Fig. 9 will explain.

By giving a plate two exposures denoted at A and B on the log exposure scale, we obtain densities denoted by the heights of the vertical lines A C and B D. The horizontal lines O A and O B, therefore, measure the log exposures in like terms.

Now apply the formula which we have previously arrived at from our definition of gamma, that is:

$$\text{gamma} = \frac{D_1 \quad D_2}{\text{Log } E_1 - \text{log } E_2}$$

In the diagram fig. 9 draw C E parallel to the log exposure base line O B

$$\text{Then gamma} = \frac{BD - AC}{OB - OA} = \frac{D\,E}{A\,B} = \frac{D\,E}{C\,E}$$

Now this ratio $\frac{D\,E}{C\,E}$ is one way of measuring the angle D O E or θ (theta) as we will call it. It is the tangent of the angle θ, the ratio of the side (in any right-angled triangle) opposite one of the other angles to the side connecting this opposite side to the angle: the ratio $\frac{\text{perpendicular}}{\text{base}}$ of our days in the elements of trigonometry.

This tangent of the angle θ, or tan θ, as it is called, is equal to gamma, for it is plain from the diagram that the angle D C E is equal to the angle C F A, which is the angle of the slope of the straight part of the characteristic curve.

We could measure the angle and find the value of its tangent in the published tables, but there is a very much simpler way of arriving at the value of tan θ by means of the chart itself. It is as follows:—

From the point 100 on the log exposure scale we draw a line H G parallel to the straight-line curve C D and meeting a vertical scale, drawn through the 1,000 point on the log E scale, at G. It is clear that since H G is parallel to C D, the angle K H G is also equal to θ and therefore tan K H G = tan θ = gamma. But tan K H G = $\frac{G\,K}{H\,K} = \frac{G\,K}{1}$ since the difference between the log of 1,000 (viz. 3) and the log of 100 (viz. 2) is 1.

Therefore, if we mark on the vertical line K G a scale corresponding with that of the densities on the left hand side of the chart the point where the parallel from H meets the scale indicates the gamma without any calculation at all.

This very simple method of ascertaining the value of gamma by means of the chart of the characteristic curve was originated by Hurter and Driffield. Mr. Watkins uses a very similar one, also illustrated in fig. 9. It will be noticed that the straight-line part of the curve when produced to meet the log E scale meets it at F (0.3 C M S.). (As we shall see later

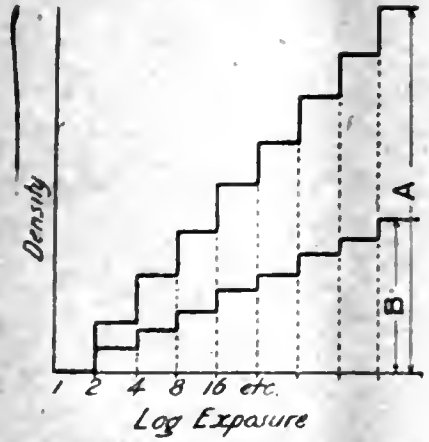

FIG. 8.—CORRECT EXPOSURE: SHORT AND LONG DEVELOPMENT.

In staircase A, representing correct development of a correct exposure, each increase of density is equal to each corresponding increase in log exposure. In B, representing a lesser time of development, the increase of density is equal at each step but less than that of the corresponding log exposure. (Hurter and Driffield.)

on this point indicates the inertia or slowness of the plate.) If from this point we set off a distance on the log E scale equal to 10 times the inertia, i.e., 10 times .3 = 3.0, the density at this point equals the gamma. Again, the base of our angle θ is 1, since it is log 10, and therefore the density value = tan θ. In the diagram it will be seen that the vertical line representing this plotted density at 3 on the log E agrees with the gamma reading on the right-hand scale. But the H and D method is the more convenient of the two. Other

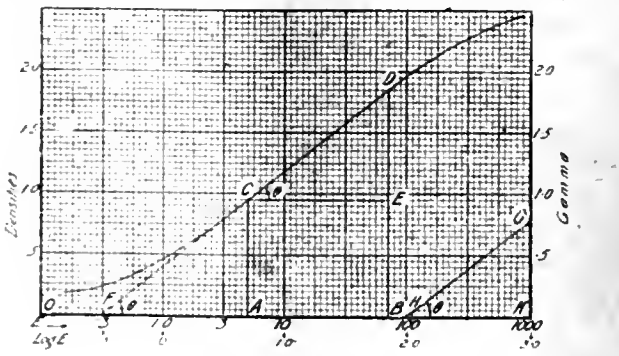

FIG. 9.—THE GEOMETRY OF GAMMA.

By drawing H G parallel to the straight part of the characteristic curve the distance K G on the right hand scale represents gamma.

methods of measuring gamma have also been devised which do not require any plotting of densities, but a description of them is beyond the scope of these notes.

Applications, June 6 to 11:—

ROLL FILMS. No. 15,633. Roll films for photography. C. W. R. Campbell.

CAMERAS. No. 15,764. Plate cameras. G. E. Cole.

CAMERAS. No. 15,668. Photographic cameras and lens and arrangements for same. G. W. Cooper.

MOUNTS. No. 15,563. Mounts for photographic prints, etc. C. W. R. Campbell.

PHOTOGRAPH FRAMES. No. 15,758. Photographic, etc., frames. Edmonds, Ltd., and H. Edmonds.

PHOTO FRAME STANDS. No. 15,881. Stands for photo frames, etc. H. A. Mackenzie.

CAMERAS.—No. 15,818. Photographic cameras. E. F. Stratton.

RADIOGRAPHY. No. 15,607. X-ray tubes. W. E. Schall.

CINEMATOGRAPHS. No. 15,721. Motion-picture machines. De Vry Corporation.

CINEMATOGRAPHY. No. 15,106. Shutters for cinematograph apparatus. W. Gardiner.

CINEMATOGRAPHY. No. 15,593. Shutter for cinematographic apparatus. S. G. Griffiths.

CINEMATOGRAPHY. No. 16,053. Cinematographic apparatus. M. A. J. Harper.

CINEMATOGRAPHY. No. 15,995. Appliance for reflecting electric arc of a cinematograph lamp upon a screen, etc. W. Holmes.

CINEMATOGRAPHY.—No. 15,912. Cinematographic apparatus. Akt.-Ges. F. Krupp.

CINEMATOGRAPHY. No. 16,043. Parlour cinematographic apparatus. W. F. Lidbury.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AERIAL PHOTOGRAPHY. No. 160,869. (October 31, 1919).—Topographical photographs taken from an aeroplane give distorted views, dependent on the angle to the vertical at which the expo-

sure has taken place. Hence a correct view of the area photographed cannot be obtained without laborious corrections, especially of areas which are not on one level.

The object of the invention is to provide apparatus whereby the photographic view can be corrected and reproduced quickly and accurately, thus converting the photographs obtained from the aeroplane into reliable and correctly proportioned maps of the area photographed.

Various methods and constructions of projection copying apparatus have been already proposed having for their purpose the correction of the flat negatives deformed by reason of their being taken on a negative at an angle with regard to the plane of the object itself. But in these constructions it was always presumed that it was possible to fix the relative and known position of these two planes so as to allow of the reproduction of the original picture on restoring the parallelism of the lines. Such methods and apparatus are, for example, described in Scheimpflug's Specifications 16,812/1906 and 1,196/1904.

The apparatus which forms the object of the invention provides on the other hand for the correction of a photograph taken from an aeroplane that is to say, from a position unknown as regards the object; all that can be supposed to be known in this case being practically limited to the centre of the photograph and the focal length of the objective.

The use of the apparatus involves two successive operations. In the first operation the apparatus is adjusted in the manner described further on to obtain, by successive experiments, the exact coincidence of the images of three reference points selected on the photograph with the corresponding points marked upon the projection screen. (Preferably and in the simplest example these reference points are points on the same contour, *i.e.*, at the same altitude). When this coincidence has been established there can be read off upon the apparatus certain factors, namely, the factors p^1, α and α', referred to below and which are needed to determine other factors i, A, MV and μ, in accordance with the formulæ referred to.

The second operation comprises the effecting of the corrected reproduction taking into account the angle of decentralisation μ obtained in the manner set forth. In order to obtain the corrected reproduction of the aerial photograph it is first necessary to determine the elements which define exactly the position of the camera in space at the moment of exposure.

These elements are as follows:—

I. The angle i of inclination at the moment of exposure of the photograph.

II. The altitude A at which the aeroplane camera is situated at the precise moment.

III. The horizontal distance on the ground between the foot of the vertical line prolonged from the centre of the photograph taken in the aeroplane to the point of the ground corresponding to the said centre.

IV. The direction of the line of greatest inclination passing through the centre of the photograph.

In order finally to obtain a corrected reproduction of the aerial photograph, it is also needful to ascertain the amount of

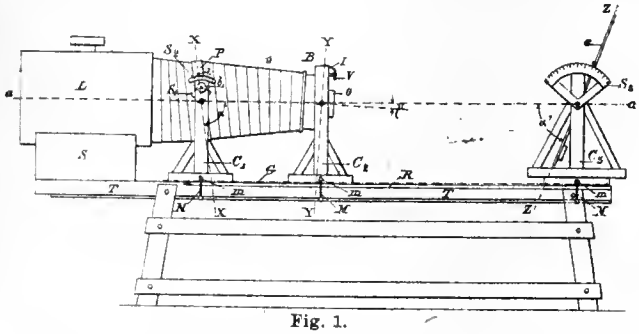

Fig. 1.

decentralisation which has to be given to the objective of the reproducing apparatus, that is to say, the angle formed by the central axis of this objective with regard to the horizontal line passing through the centre of the nodal points, in order that such objective may occupy the position corresponding to the angle at which the corrected reproduction must be effected; this angle which we call the angle of decentralisation will be indicated hereafter in the specification by the Greek letter μ.

The apparatus forming the object of the present invention enables the user quickly to ascertain the data above set forth in the manner which will now be explained.

In the drawings *a*, *a* indicates the principal axis of the apparatus; X—X the plane of the negative; Y—Y the plane of the objective, and Z—Z the plane of the reproduction frame.

The apparatus comprises a table T supported on legs and provided with rails on which the moving parts of the apparatus travel. The lantern L (preferably an arc lamp of 15 ampères,

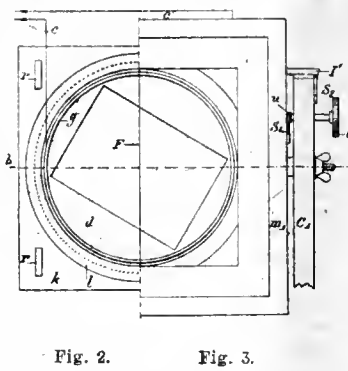

Fig. 2.

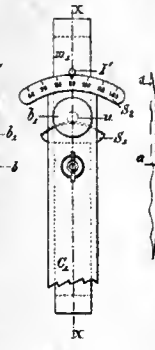

Fig. 3.

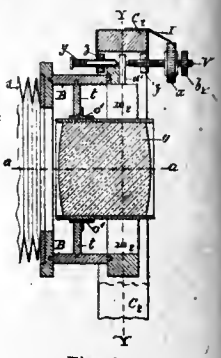

Fig. 4.

Fig. 6.

110 volts) is supported on the foot S and raised about half a metre above the table level. The negative holder P is supported by the frame C_1, the objective O by the frame C_2, and the reproduction plate *e* by the frame C_3; all these frames travel on the rails of the table T and are adjusted by hand by means of pinions *m* engaging in the rack C on the table, the pinions being turned by the handles M.

The negative holder P and the lantern body L are connected light-tight to the box B enclosing the objective by folding bellows in the usual manner.

The angle α corresponding to the inclination of the negative with relation to the horizontal is measured off on the graduated scale S^2 fixed to the support C^1 by means of the pointer 1.

The angle α' corresponding to the inclination of the plane of projection Z—Z with relation to the horizontal line *a a* is measured off on the scale S^3 fixed on the vertical support of the carrier C_3.

The relative positions of the negative lens and the focal plane *e* are determined by aid of the scale R fixed upon the table T.

In order to adjust the position of the negative in its own plane, the negative carrier is constructed as shown in figs. 2 and 3 having the disc *d* with an aperture for the negative exactly centred. The rotation of the disc in the plane of the negative may be effected in any convenient way, for instance, by means of the wheel *q* and cords c.

The disc *d* and the external support in which it turns are encased in the grooved frame *k* rotatable on its horizontal axis *b*, *b*. As shown in figs. 3 and 4, this turning is effected by means of the toothed sector S^1 fixed upon the upright m^1 engaging with the pinion *u* actuated by the milled stud b^1. The pointer I^1 on the frame m^1 facilitates the adjustment, *l* are brass rings; *r* check springs in the frame, F a wire in the vertical plane through the centre of the plate holder.

In order to adjust the objective to the angle at which the projection must be effected, the principal axis of the objective is caused to swing about the horizontal passing through the centre of the nodal points.

The corresponding angle is designed by the letter μ (so-called angle of decentring); the angle corresponds to the decentration of the objective relatively to the principal optic axis of the apparatus and to the centre of the plate.

The adjustment of the objective may be obtained by various means, and in particular by means of the construction illustrated in figs. 6 and 7, in which:—

Y—Y indicates as in fig. 1 the plane perpendicular to the optical axis of the objective passing through the centre of the nodal points.

C_3 indicates the supports of the carrier of the objective.

m_2 the supports of the frame fixed to the horizontal axis of rotation.

B the box supporting the objective O and connected to the negative holder of the bellows *s*.

t indicates the plate supporting the objective.

O^t a metal ring supporting the objective.

a^1 a piece of brass forming a straight-edge.
V a set screw.
x a milled and graduated disc.
b^3 a fine adjustment screw disc.
I a pointer fixed to the objective carrier C^2.
y a spring-supported plunger resting against the straight-edge a^1.
z screw nuts.

The use of the apparatus above described is as follows :—

The photograph is first roughly orientated in the plane of its support P, taking into account that the parts of this photograph which are to be most magnified must be projected upon the upper part of the screen e. Then by means of successive experiments the operator seeks to obtain the perfect coincidence of the image of the three reference points selected upon the photograph with the corresponding points marked upon the projection screen. In order to obtain this, he turns the handles m, which move along the graduated scale R, the frame C^1 supporting the photograph, the frame C^2 supporting the objective, and the frame C^3 supporting the projection screen e; the photograph is also adjusted in its plane, and there is also adjusted on the screen e the plotted sketch upon which the reference points have been marked. As soon as this coincidence has been established and the perfect sharpness of the corresponding images secured, the operator reads upon the scale R the dimensions p and p^1, which correspond to the well-known general optical formula :—

$$\frac{1}{f} = \frac{1}{p} - \frac{1}{p^1}$$

in which f denotes the focal length of the objective O and p, p^1 the distances which determine respectively with regard to the centre of the objective the position of the centre of the photograph and that of the horizontal axis of rotation of the projection screen.

The operator can also read off on the Sectors S^2 and S^1 respectively the angles a and a^1, which determine the inclination of the planes of the photograph and of the projection screen respectively in relation to the general optical axis a—a of the apparatus in question.

The knowledge of these lengths and of these angles admits of the immediate determination of the value of the factors referred to at the commencement of this specification, which factors are necessary to obtain a corrected reproduction of the aerial photograph. It will be at once noticed that one of these elements, that is to say the direction of the line of greatest inclination passing through the centre of the photograph, is marked upon the projection screen e by the photographic image of the wire F stretched in the plane of the picture and passing through the centre of this latter.

The other elements are defined by means of formulæ set forth in a complete study of the photo-restitution apparatus which forms the subject of a book deposited in the Library of the Patent Office, entitled "Application of Aerial Topographic Views

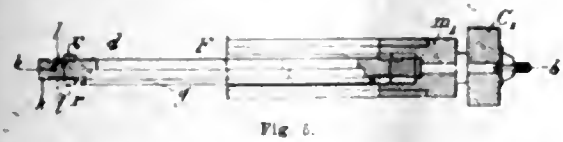

Fig. 6.

Apparatus for Photo-Restitution," by H. Roussilhe, Chief Hydrographic Engineer.

The formulæ are very simply ascertainable in practice, because the focal length of the photographic objective employed in the camera can be the same as the focal length of the objective employed in the reproduction apparatus. In practice, the objectives used for taking from the aeroplane photographs of 18 × 24 at an altitude varying between 1,500 and 2,500 metres have a focal length of about half a metre. This focal length is hereinbefore indicated by the letter f according to the formula :—

$$\frac{1}{f} = \frac{1}{p} - \frac{1}{p^1}$$

and will be indicated by the same letter in the formula No. 5 given further on.

Further, in practice with negatives 17 × 24 cm. taken at an altitude A between 1,500 and 2,500 metres, the scale E of reproduction which is adopted is equal to the inverse of the mean altitude, that is to say that $E = \frac{1}{2{,}000}$.

Under the aforesaid conditions the formulæ giving the angle i, the altitude A, the situation of the foot of the vertical from the camera negative on the horizontal plane selected as the base and the angle of decentering μ, are the following :—

(1) $\cos i = \frac{\sin a'}{\sin a}$

(2) $A = 1{,}000\,(2p^1 - 1)\cos i$,

(3) $MV = 1{,}000\,(2p^1 - 1)\sin i$.

In this formula M indicates the point on the ground corresponding to the image of the centre of the negative, and V indicates the foot of the perpendicular from the camera station.

(4) $tg\,\mu = \frac{\sin i \cos i}{2K\,(K + \cos i)\sin a}$.

In this formula K indicates a coefficient which is given by the equation :—

(5) $K = \frac{A.E}{f}$

that is to say a coefficient which is well determined when the altitude A is known, the values of the quantities E and f being themselves known as above specified.

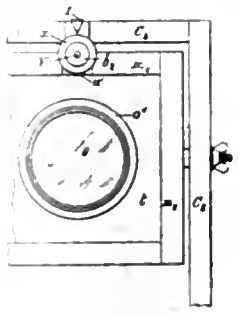

Fig. 7.

By reading the values of the angles a and a' on the graduated scales S_2 and S_1 respectively, and the value of the length p^1 on the scale R, it is possible to obtain immediately the values of the quantities i, A, MV and μ above specified.

For the rapid calculation of the quantities, suitable graphs or abacuses can be worked out for giving immediately the corresponding values. These abacuses and the manner of using the same are explained in detail in the French book above referred to.

It is to be observed that if the selected reference points above specified in paragraph I of this specification are not on the same contour, i.e., at the same altitude, the coincidence of the points cannot be obtained exactly in a single operation, and this latter constitutes only a first approximation which must be completed by additional calculations and corrections necessary for exactly positioning the negative, the objective and the projection screen; these subsequent operations are dealt with at length in the book referred to, and it is unnecessary to give a complete explanation of them in the present specification.—Henri Roussilhe, Soisy-sous-Etiolle, Seine et Oise, France.

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Cracket, 10, Parkgrove Terrace, Tollcross, Glasgow.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, JUNE 28.

Hackney Phot. Soc. "Desensitol." The Ilford Co.
Manchester Amateur Phot. Soc. "More about Carbro." J. Chapman.
Scottish C.W.S.C.C. (Glasgow). Holiday Hints.

WEDNESDAY, JUNE 29.

Bradford Phot. Soc. Evening Excursion to Tong.

THURSDAY, JUNE 30.

Hammersmith (Hampshire House) P.S. "Lighting in Portraiture." S. Taylor.

SATURDAY, JULY 2.

Manchester Amateur Phot. Soc. Ramble to Poynton Park.

CROYDON CAMERA CLUB.

A paper on "Surnames, Photographic and Otherwise," mainly based on the investigations of Prof. Weekley, was read by Mr. F. Ackroyd. Surnames, he said, became fixed in about the thirteenth century, and he interestingly classified and described the origin of a large number.

One learnt that the name "Harpur" descends from a musical instrument, hence Mr. Harpur's fondness for the gramophone. By direct descent from Job, Mr. Vivian Jobling exists, but with sadly changed character, for tread on his toes and the band plays. "Brown" merely indicates that some past Brown was brown or ginger—an appropriate name for a photographer, the lecturer thought, in these sepia-toning days. Surnames are often not what they sound, "Boosey," for instance, originally meaning a cattle buyer.

In the discussion, Mr. Gardner regaled all with many good tales dating from about the same period as the fixation of surnames.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, on June 10. There were present Messrs. Marcus Adams, A. Basil, A. Bennett, Frank Brown, W. B. Chaplin, Gordon Chase, T. Chidley, A. Corbett, C. F. Dickinson, Alfred Ellis, S. H. Fry, W. E. Gray, R. Haines, G. Hana, W. Illingworth, H. Lambert, H. A. St. George, R. N. Speaight, F. G. Wakefield, A. Swan Watson (president), W. H. O. Wedlake, and H. Wheeler, and Lang Sims (secretary). Mr. Alfred Ellis took the chair, and apologies for absence were read from Messrs. Chapman, Read, and Turner.

The secretary reported, with regard to Mr. Fry's letter of resignation from the Council, that he had written to Mr. Fry, who had now consented to continue his membership, although unable to attend the meetings with the regularity he desired. A letter was also read from Mr. Fry acknowledging very feelingly the gift of the souvenir presented to him by the members of the Council.

With regard to the application of a lady for membership, and the deferring of the matter until it was found whether the position she occupied in a business was one which made her eligible for membership, the secretary reported the result of his inquiries, and these being satisfactory, her application was agreed to.

The secretary also reported that the dispute between the two photographers (particulars of which were brought before the last Council meeting) was on its way to settlement. A copy of "Le Photographe" of May 20 was also brought forward, in which appeared an interesting account of the recent Congress. A cordial letter had also been received from the Editor of this publication.

The report of the Cape Section of the Professional Photographers' Association had also been received, and showed that the Section had made considerable progress. The Council in London were asked to accept exhibits from this Section for the next exhibition, and a cordial letter had been sent in reply.

Among other correspondence, the secretary reported that Messrs. Burroughs Wellcome and Co. desired to include in their forthcoming handbook the amended scale of reproduction fees, fixed by the Association, and this was agreed to. With reference to the new postal arrangements, the secretary reported that he had, after consultation with the chairman of the Council and the solicitor, sent a letter to the Postmaster-General in the name of the Association protesting against the proposed increase in postal charges, and had also seen Sir Davison Dalziel, Bart., M.P., on the subject. The Council unanimously endorsed this emergency action.

The secretary read particulars of three applications for membership: M. E. Brough (Hampstead), Andrew Paterson (Inverness), and Reginald Alec Rower (Reading). These were accepted, together with one resignation.

A letter was read from a member of the Council (Mr. Marcus Adams) with regard to an extortionate charge made against a well-known firm by a firm of photographers (not members of the Association) for some photographic work, and, after some discussion, it was agreed that the Council could take no action in the matter.

The secretary read a letter from a member, a lady photographer, complaining of the somewhat unscrupulous activities of a canvasser in her neighbourhood. Mr. Brown suggested that it might be the same canvasser who had already received a serious warning in his own locality, and he agreed to write the complaining member on the subject.

The secretary reported that he had compiled a list of towns which, it was hoped, would form in time a complete directory of professional photographers, members of the Association, arranged according to their localities.

The Council then turned to the consideration of the draft Memorandum and Articles of Association and devoted several hours to their detailed consideration, Mr. Vaughan (the honorary solicitor) being present. The chairman said that he himself had already spent the best part of three days on the draft. He had also spent a day with the secretary, going over the suggested emendations and additions which had been sent in by various members of the Council. A meeting of London members had been held, and subsequently a day was spent with the solicitor. The result of these labours would be brought before the Council meeting that afternoon for confirmation or alteration as the Council saw fit, and he proposed to go through the Memorandum and Articles clause by clause. One member of the Council wanted the title altered to "The Institute of Professional Photographers," but this matter was decided in the negative by a vote at the annual meeting, and therefore could not be reopened. The solicitor said that he would like to remark that all the criticisms sent in by members of the Council were practical, and showed how much care and thought had been bestowed upon the document. The various clauses were then taken seriatim.

The Council adjourned after a sitting of four-and-a-half hours

THE R.P.S. EXHIBITION.—The following is the complete list of judges who have kindly consented to act at the Royal Photographic Society's 66th Annual Exhibition, to be held at 35, Russell Square, from September 19 to October 29:—Section I.—Pictorial: Messrs. Marcus Adams, Bertram Cox, Dr. Charles Jaeger (Member of the Pittsburgh and Los Angeles Salons), J. Dudley Johnston, Alexander Keighley, F. J. Mortimer and Hector Murchison. Section II.—Colour Transparencies and Colour Prints: (a) Pictorial, Messrs. F. T. Hollyer and W. L. F. Wastell, (b) Scientific and Technical, Messrs. Charles R. Davidson (Royal Observatory, Greenwich), J. Willis Grundy, Robt. Knox, M.D., F.R.M.S., Hugh Main, B.Sc., G. H. Rodman, M.D. Section III.—Scientific and Technical Exhibits, Natural History Photographs, Lantern and Stereoscopic Slides: Messrs. Charles R. Davidson (Royal Observatory, Greenwich), J. Willis Grundy, Robt. Knox, M.D., F.R.M.S., Hugh Main, B.Sc., G. H. Rodman, M.D. Attention may be drawn to the following alterations in the rules concerning the Pictorial Section:—Photographs in this Section must be on white or cream mounts of the following standard sizes: 24 x 19 inches, 19 x 16 inches, or 16 x 11 inches, and not more than four photographs may be submitted for selection.

News and Notes.

CANADIAN IMPORTS.—A resolution adopted by the Canadian Parliament provides that goods imported into Canada from October 1 next shall be marked or stamped in English or French so as to indicate the country of origin.

ART NOT A LUXURY.—During a debate on duties on manufactured goods in the House of Commons last Thursday, Sir Martin Conway is reported by "The Times" to have said that "no work of art was a luxury," and asked "what did civilisation exist for except to produce works of art?"

BUTCHER'S "CAMERA HOUSE JOURNAL" for June contains particulars of many new things of interest, e.g., an electric dark-room lamp, over-size printing frames for roll films, Japanese tissues for cleaning lenses, and a holder for old Gillette razor blades for use as print trimmers.

KODAK IN CHINA.—A Reuter telegram states that a large number of Chinese have taken up amateur photography as a hobby and their numbers are growing day by day, and with a view to developing the business of supplying photographic goods Kodak Ltd., of London, has lately established a branch in Shanghai, a distributing centre for China.

AN AMERICAN SLOGAN.—It is stated in "Pure Ginger" which is the title of the monthly news sheet of the Photographers' Association of America—that the slogan in use to-day is "Be Photographed This Year on Your Birthday." A prize of 250 dollars is offered by the Association for a new slogan, to be made known at the Buffalo Convention next month.

NEW "WESTMINSTER" LISTS.—Two new lists of second-hand and shop-soiled photographic apparatus have reached us from the Westminster Photographic Exchange, Ltd., of 111, Oxford Street, W.1, and 119, Victoria Street, London, S.W. The lists, each of over forty pages, contain particulars of some hundreds of cameras, lenses, etc., and copies will be sent to any of our readers who apply to the firm for them.

A BIG ROSS LENS.—A writer in the "Westminster Gazette," referring to the collection of early photographs—mainly studies of flowers—the work of Mr. Stevens the well-known auctioneer, says:—"He (Mr. Stevens) has shown me the lens with which these were taken—a most formidable instrument by Andrew Ross, heavy enough to confine the photographer in his picture making to the immediate vicinity of his house. I suppose the brass mounting would hold something like a gallon of liquid. The original cost of that lens was £90, which brings it near to some of the largest anastigmats now made, so far as price is concerned. The back lens itself must be eight or nine inches in diameter, and the focal length some feet, while the working aperture is small. Such a lens working on plates fifteen inches by twelve, would give a clearness and precision of definition such as would not be excelled by the finest anastigmat to-day, but only because the photograph was confined to a small part of the field of the lens."

FACE FASHION CHANGE.—The lay press gravely informs us that Madonna faces are to be fashionable this season, and should the fashion become the craze—as the leaders of fashion hope it will—photographers will no doubt have a busy time. A "Daily Chronicle" reporter, on hearing the news wended his way towards the West End to ask certain experts if women really could change their faces, and he was told that they could. That is, they can make alterations in certain little points, which have the effect of giving a totally different effect to the same features. Hair parted in the middle and smoothly turned back from the ears would be a necessary part in a Madonna "make-up." Women who wish to dress up to that ideal must remember, too, to keep their eyes downcast, to smile slowly and sadly, to clasp their hands demurely in front of them, and, whenever possible, to carry a book with a binding which suggests serious meditations. Plain gowns, beautifully and artfully cut—which, by the way, will probably cost as much each as two "frilly" frocks—will fill in the picture. Small hats with plain, long veils will help to maintain the illusion. These are mere suggestions. Clever women who want to attain the fashionable face will think of others for themselves.

Correspondence.

*** Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

POSTAGE ON PICTURE POSTCARDS.

To the Editors.

Gentlemen,—In addition to being a professional photographer and a maker of picture postcards, I have also a stationer's business, in which I deal largely with picture postcards of all kinds. Many others besides myself have been trying to solve the problem of the new and increased rates of postages on cards, and what will go through the post for a penny.

The problem is a rather puzzling one, and the increase of a halfpenny on the postage of a postcard—small though the increase be—is likely to lower the sale of commercial postcards, though, happily, it will not make much difference in the business of taking postcard portraits, for the simple reason that such portraits (those taken privately) are rarely sent "naked" through the post, but are usually enclosed in a letter.

However, much doubt exists, and your readers may be interested to know that under the heading of "Postcards—what are they?" a circular has been sent out by the Central Districts Branch of the London Master Printers' Association.

After referring to the new rates which came into force on June 12–13 last, the circular goes on to give the following facts, which I am sure will interest all your readers:—"There are several kinds of postcards in use, namely: (1) The picture postcard on which a communication in the nature of a letter may be written, 1½d.; (2) the official postcard, on which a communication in the nature of a letter may be written, 1½d., (3) printed Christmas, New Year, Easter, birthday picture and visiting cards on which formulæ of courtesy, not exceeding five words, may appear. The date, name and address of sender and addressee may also appear; (4) a printed card (postcard size) bearing a business announcement on the back, and on the front the words, 'Printed Paper Rate.' The left-half on the front can also be used for printed matter, leaving the right-half for the address, 1d. Millions of this class of card are used by commercial, industrial, and publicity firms, etc.

"Another fact not generally known, is that a card can be sent through the post measuring up to 24 inches by 12 inches containing a business announcement on the back and on the front the words 'Printed Paper Rate.' The left-half on the front of the card can also be used for printed matter, leaving the right half for the address, 1d. The P.M.G. may explain that numbers 3 and 4 come under heading of printed paper rate, but the general public will better understand the explanation given above. A card sent through the post, whether it is a picture card, official card, or a printed paper rate card, is to all intents and purposes a postcard."—Yours faithfully,

H. GREEN.

COOLING THE TANK.

To the Editors.

Gentlemen,—During the present spell of hot weather, when the temperature of the developer has ranged between 70 and 76 deg. Fahr., I have had trouble with flatness and general veiling of the shadows, together with an increased tendency to halation in portrait subjects when using ultra rapid plates.

By increasing the concentration of the developer and adding extra bromide, shortening the time of development in accordance with the augmented strength of the solution, the trouble has been got over, and negatives with clear shadows and of good density have been obtained.

The increased concentration was got by adding one-half as much again of the stock solutions (pyro and soda), and the same of the bromide, then developing for three-quarters of the normal time. For finding the times of development at varying degrees of temperature, Anderson's Calculator has proved reliable.

Your note in last week's issue on cooling down the tank developer leads me to give the above alternative method, as it appears to me that if the developer is cooled down beforehand, the temperature may rise sufficiently during development to upset one's calculations.—Yours faithfully, ALBERT O. FORREST

Pontypridd

FINE ART ESSENTIALS.

To the Editors.

Gentlemen,—Whilst thanking you for your pleasant surprise in the shape of your editorial note commending my Course, may I point out that the postal direction you gave as W.C.2 will probably divert many inquirers to John Street, Adelphi. The address of the Course is: The Art of Life Movement, 28, John Street, Bedford Row, W.C.1.—Yours, etc., F. C. TILNEY.

RADIOLOGISTS AND RADIOGRAPHERS.

To the Editors.

Gentlemen,—In your issue of June 10 I notice you refer to medical men as Radiographers and to others as lay-workers. This is not so. Medical officers are known as Radiologists, and qualified non-medical men as Radiographers.—Yours faithfully,

A. O. FORDER,
Radiographer, King's College Hospital.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. C.—We must confess we are at a loss to explain the reason of your failure, but would suggest that the print had come in contact with another in either the fixing or bleaching bath in such a way that the solution was not allowed to act properly.

D. J. C.—There is no very cheap soft focus lens on the market, but an excellent substitute will be found in the front lens of a small Petzval lens used at full aperture. This will work at about *f*/6, and will give quite a considerable amount of diffusion, quite as much as your sitters will care for.

R. L.—The pyro-soda formula required is probably that advocated by the Rev. H. O. Fenton, namely: (A) Water, 18 ozs.; pot. metabisulphite, 60 grs.: pyro, 120 grs. (B) Water, 20 ozs.: soda carbonate (anhydrous), 1 oz.; soda sulphite (anhydrous), 1 oz. For use take A, 1 part: B, 1 part and water, 1 part. Factor 6.

H. J. S.—We constantly use a hypo-metabisulphite fixing solution made as you describe, and have found it to keep fairly clear. We should advise you to try chemicals from another source. If there is still a precipitate it is probably due to your water supply. Have you tried filtering out the precipitate, and does a precipitate occur without any plate having been fixed?

A. G.—(1) We do not know of any book entirely devoted to pastel finishing. Winsor and Newton, 37-40, Rathbone Place, London, W.1, publish one on crayon drawing and painting, and there is a good deal of useful information in "Johnson's Retouching and Finishing," published by Messrs. Marion. (2) We have found a small piece of camphor floating on gum to keep it from moulding but we prefer a very small trace of pure carbolic acid.

S. S. P.—If the cards are actually copies of yours—you should be particular to satisfy yourself as to this, e.g., by their inclusion of figures—they are palpable infringements, and you are entitled to delivery of all stocks of them and also damages. Both makers and sellers of the infringing cards are equally liable; it will probably be better to address yourself to one or two retailers. First write asking them what they propose to do, and without naming any sum. It may then be necessary to send a solicitor's letter. It is immaterial whether copyrights were, or were not, registered under the old Act.

P. T. M.—(1) The permanganate, iodine-cyanide, and the Nietz permanganate-persulphate reducers given on page 278 ("B.J.," May 13) act as reducers of negatives and bromide prints. As regards gradation, the effects on negatives and bromide prints are broadly as indicated in your question, although it is not very clear from the paper if measurements have been made on bromide prints. The Nietz formula undoes, so to speak, the effect of continued development; permanganate, rather more "softening" effect than this: iodine-cyanide, less. (2) For bromide, same strength; for negatives, say double

J. M.—(1) We do not think there would be any appreciable difference between the lenses you mention and those of other first-class makers. (2) It is usual for users of cinematograph film to do their own perforating, although the makers will do so if requested. Again, we must say that you will find no appreciable difference between various makers. (3) We do not think you will, with any certainty, get the colour you require from either of the processes you mention. Vanadium is very uncertain as to colour. Probably a process of treating the image with a bleacher and dyeing it (as was done in the Kodachrome process) would give you the colour you require.

P. H.—The synopsis of your proposed lecture is very good, and we cannot suggest any further headings. Latimer Clark and Josiah L. Clark are the same, his full Christian names being Josiah Latimer. You will find all the biographical details you need in the "Dictionary of National Biography" (Supplementary Volume, 1909). His camera for taking stereoscopic pictures with a single lens was invented in 1853 (see "Journal of Photographic Society," May 21, 1853). According to the "Dictionary" named above, there is a good portrait of him in Bright's "Life of Sir C. T. Bright" (ii., 19), the latter being at one time in business partnership with Latimer Clark, not, however, in photographic work.

W. E. D.—Your practical friend probably alluded to contact printing with the enclosed arc when he said that it "got through" the silver deposit. We have, however, successfully made hundreds of carbon prints by this light from fairly strong negatives. We do not think, quite irrespectively of colour of light, that carbon enlargements can be made in a reasonable time by projection, even if continuating action is utilised, otherwise such firms as the Autotype Company would not make enlarged negatives to obtain single prints. A cinematograph arc lamp would probably be the most satisfactory illuminant, but even with this a great degree of enlargement could not be obtained.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3191. Vol. LXVIII. FRIDAY, JULY 1, 1921. Price Fourpence.

Contents.

SUMMARY.

In our next issue (July 8) we shall commence a series of chapters on photography for the newspapers by Mr. Lancelot Vining, late art editor of the "Sunday Pictorial."

Mr. Alfred Watkins contributes an important article on testing development speeds of plates, a point Messrs. Hurter and Driffield explained, but did not tabulate or standardise, and describes a most ingenious calculating instrument he has made. (P. 383.)

In a second portion of the chapter on the H. and D. doctrine, dealing with the effect of development upon the contrast or gamma of a negative, the variation in gamma which is necessitated by the different contrast properties of printing papers is considered and illustrated by a partial though not completely accurate description of the behaviour of printing papers. (P. 386.)

Many photographers find a difficulty in calculating the focal length of lens which is permitted by studios of different sizes for particular classes of work. In a leading article we give and explain a simple formula which, though not of universal application, is quite sufficiently accurate for the particular circumstances of studio portraiture. (P. 382.)

In a contributed article Mr. R. R. Rawkins points out the widely different degrees of quality obtained by different photographers with the same printing paper, and emphasises the need of greater consideration of the characteristic qualities of printing media and the importance of negatives appropriate to them. (P. 388.)

Under-exposure, followed by over development, is probably a cause of want of success with panchromatic plates which is overlooked by beginners in their use. (P. 381.)

Entry forms for the Royal Photographic Society's sixty-sixth annual exhibition are now ready and obtainable from the Secretary, 35, Russell Square, W.C.2. (P. 390.)

A full report of the Memorial Lecture on the Life and Work of Sir William Abney appears in the July issue of the Royal Photographic Society's "Journal." (P. 390.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Details of an instrument serving for both the taking and projecting of two-colour or three-colour cinematograph film pictures have recently been given in a patent specification of Mr. E. C. S. Parker. (P. 25.)

Some of the considerations which are of importance in obtaining pleasing effects in pictorial photography, particularly as regards composition and massing of colour tones, are dealt with in an article on page 27

EX CATHEDRA.

Exposures and Panchromatic Plates.

Many photographers when working panchromatic plates for the first time fail to get the finest possible results through overlooking the fact that these plates demand a full exposure if their highest qualities in the matter of colour rendering are to be obtained, particularly when the subject is composed of great extremes of light and shade. It is sometimes imagined that anything like over-exposure tends to give the snowy effect, very much like over-correction, that is sometimes found upon photographs taken upon these plates. But this is quite a mistaken idea; for the defect referred to is far more likely to be caused by under-exposure, coupled with over-development. For exposures to be always accurate an exposure meter should be consulted, and no harm will be done if double the indicated time is given. An experience of the Paget colour process confirms our belief that the best colour renderings upon panchromatic plates will be obtained upon very fully-exposed negatives, together with a development stopped well before the image gains great density. If any photographer who has not been so successful as he desired with panchromatic plates will try the experiment of exposing by meter and developing with one of the modern single-solution concentrated developers, by the time and temperature system, using a factor for soft contrast, and thereby standardises his working conditions, we venture to predict that a very much better technical standard of results will be achieved.

* * *

Camera Cases.

Many photographers pay far too little attention to the camera case, especially when we come to consider the amount of wear the average camera is subjected to, be its user amateur or professional. We were reminded of this only the other day when we saw a photographer using one of the high-grade pocket cameras, which he carried in a limp canvas case that was obviously neither proof against dust or hard usage. Speaking of the term pocket camera it may be pointed out that the pocket is one of the least suitable places for the carrying of a good camera, unless it be one of the ultra small instruments so constructed to be entirely dustproof, a difficult proposition; and even then a well-made leather case would be required if the good appearance of the instrument is to be preserved. Some time ago we were shown a nearly new 3½ x 2½ pocket plate camera that had travelled some hundreds of miles in its owner's pocket upon a cycling holiday—its condition had to be seen to be believed. Experience teaches us that though a well-made leather case is a more or less expensive item, and is listed by camera manufacturers as an extra, it should be regarded as essential, particularly if the camera is a small and valuable one, like many of the pocket instruments in use to-day. The older-fashioned type of field camera is capable of standing a great

amount of rough usage without showing any ill effects, but the modern small camera cannot be put in the same category as its more solidly-built predecessor, and if it is not given due protection, trouble, sooner or later, is certain to occur.

* * *

Colour Screen Photography. Photographs by one or other of the screen-plate processes have been produced mainly by amateurs in the past. Only a few professional workers have touched this class of work, and they, we believe, without much financial success, due perhaps to the idea that the demand would be greater than it actually has been. During the war materials were practically unavailable, but at present it is possible to obtain at least two makes of colour plates, Autochrome and Paget, and it might be worth the while of photographers with a well-to-do clientèle to make a trial of them. The process is, perhaps, at its weakest in portraiture, but there is plenty of scope in other directions, such as views of gardens, reproductions of works of art, flower pictures and the like. The working is not a matter of great difficulty, and the speed with which a finished result can be obtained is attractive. Among many members of the public there is an interest in Autochrome transparencies, whilst the special facility of the Paget process in affording a number of identical transparencies, *e.g.*, for lantern projection, has its appeal to others.

THE LENS IN REFERENCE TO THE SIZE OF STUDIO AND DESCRIPTION OF WORK.

One of the most frequent inquiries which is put to us by portrait photographers relates to the most advisable choice of focal lengths of lens for a studio of given size. Very often the particulars which accompany a question of this kind are not sufficient for a useful answer to be made. After all, if the dimensions of a studio are comparatively small, the use of only one lens inevitably sacrifices something in one direction or another. In a studio of 30 ft. to 40 ft. run, it is different; and a lens of 10 or 12 inches focal length can be used for all descriptions of work. For some years past we have published in the "Almanac" a table which gives a fairly comprehensive guide to the choice of a lens under the conditions which are determined by the length of the studio and by the size of a portrait negative which it is required to make from a full-length, half-length, or head and shoulders subject. It is possible, however, to prescribe a comparatively simple arithmetical rule by which anyone can work out for himself in a few seconds on a postcard the focus of lens which is necessary under any given conditions.

Before explaining this rule in a few words, it is, perhaps, worth while pointing out once again that where the conditions permit it is always advantageous to use a lens of the longest focus, at any rate up to a focal length of about 12 inches. Beyond that focus it may often not be advantageous to go, chiefly for the reason that a longer focus further increases the distance between the sitter and the camera without material benefit to the "drawing" of the subject, and frequently with disadvantage to the quality of the negative if the atmosphere of the studio is even to a slight extent obscured by fog. On the other hand, it must be borne in mind that the focal length which is the longest permissible in a given length of studio for a given class of work may still be too short for covering the plate to be used. In such a case the alternatives which present themselves are, first, to resign oneself to the circumstances and be content with head and shoulders or half-length instead of full-length, or, second, to sacrifice speed of lens and obtain the necessary covering power by means of a smaller aperture, or, as may sometimes be necessary, by means of a slower type of lens.

Coming now to the method of calculation to which we have referred, let it first be borne in mind that as a rule the distance between the sitter and the plate, which is all that we are concerned with from the optical standpoint, usually requires to be a few feet less than the over-all length of the studio. A foot or two requires to be provided for placing of the background behind the sitter, and likewise a foot or two behind the camera. A fair allowance for both these together is 5 ft., so that in the calculation to be referred to the so-called "studio space" requires first to be arrived at by making the necessary reduction from the over-all length. In some cases, for example, where there is a doorway at one end of the studio, subtraction of a lesser length than 5 ft. can be made.

Optically, the factor, apart from the focal length of the lens, which determines the space required, is the degree of reduction in photographing; that is to say, the height of the sitter divided by the height of the image on the focussing screen. Taking the height of a full-length standing figure as averaging 68 inches and of a head and shoulders as averaging 30 inches, it is a simple matter to draw up a little table which will show the degree of reduction—reduction figure, as we will call it—for various descriptions of work. Such a table is the following:—

Name and size of photograph	C. de V.	Cabinet.	Boudoir*	Imperial†
Height of image on photograph	3	5	7½	9
For full-length portraits, reduction figure is ..	23	13	9	7½
For head and shoulders portrait, reduction figure is	10	6	4	3 nearly

* 8½ × 5. † 10 × 6⅞.

The reduction figure in any particular case can very easily be found. It is found by dividing the longest dimension of the subject by the corresponding dimension of the image required in the photograph, both being expressed, of course, in inches. For example, if a group of people occupies, say, 6 ft. across the studio and it is required to make a whole-plate photograph in which the width of the image is, say, 8 inches, then the reduction figure is simply 72 inches (=6 ft.) divided by 8, that is to say, 9.

Now for our rule, which is as follows:—The greatest focal length of lens which can be used for a given description of work is equal to the "studio space" divided by a number which is the reduction figure plus 2; that is to say, if the reduction figure is 10, the divisor is 12. This rule can be perhaps set out more plainly in a kind of formula—

$$\text{Focal length} = \frac{\text{Studio space}}{\text{R} + 2}$$

where R is the "reduction figure."

This rule is not an absolutely correct one, because it leaves out of account the extra camera extension which is required when photographing objects which are nearer than the "infinity" corresponding with a camera extension equal to the focal length of the lens. But this factor is a very small one in the case of reduction figures from about 24 to 10; and in the case of smaller reduction figures (that is to say, copying on a larger scale), the

error is of no importance since, in these circumstances, there is always ample room in the studio even for a lens of much longer focus than is likely to be available or desirable.

One or two examples will serve to remove any difficulty which even those quite unacquainted with optical calculations may experience. Suppose we are making full-length cabinets in a studio of an over-all length of 20 ft. Allowing 5 ft. as pointed out above, the studio space is 15 ft. For reduction of a full-length figure to cabinet size, the reduction figure is 13. Therefore, the greatest focal length which can be used is the studio space (15 ft. = 15 × 12 inches) divided by 15 (reduction figure plus 2), that is to say, the focal length is 12 inches. On the other hand, if the studio space were only 10 ft., corresponding with an over-all length of 15 ft. the greatest focal length which could be used for full-length cabinets is 8 inches. Here it will be seen that the maximum permissible focal length is somewhat too short to allow of a portrait objective being used, since the covering power of the average *f*/4 Petzval lens is insufficient for a half-plate. An anastigmat of from *f*/5.6 to *f*/8 aperture would, however, cover a plate of this size satisfactorily.

In the case of the smaller reductions, it will be seen that the formula indicates that there is ample margin for choosing a focal length considerably less than the maximum permitted by the studio space, whilst still affording ample covering power. For example, if the available studio space is 15 ft., what is the maximum focal length which can be used for an Imperial head and shoulders portrait? From the table, the reduction figure in this case is 3, so that the maximum permissible focal length is 15 × 12 ÷ (3 + 2) = 36. Although for such close-up portraits there is certainly an advantage in using a long focus, for the sake of good "drawing," yet few portrait photographers would think it necessary to employ a focus of such length as 36 inches. For one thing, if the relative aperture was large, the lens would be enormously bulky; and also the difference in "drawing" between a 36-inch lens and one of 20 or even 15 inches focus would not be very large. This, however, is a side issue from the subject which we have endeavoured to set forth in the simplest manner in these notes, which are written simply to indicate a most simple method of calculating the greatest focal length which can be used in a studio of given dimensions for various descriptions of work.

TESTING DEVELOPMENT SPEEDS OF PLATES.

The speed method of Messrs. Hurter and Driffield provides a means of measuring and recording the degree or steepness of development attained in the development trial of a plate. This result they term the development factor. They point out that in another trial the same development factor will be attained if the same batch of plate is developed in the same developer for the same time at the same temperature. But that a change of temperature will (other factors remaining unaltered) result in a different development factor. Also that different makes and batches of plates attain different development factors even when developer, time, and temperature are standardised and fixed.

Since their researches, other investigators have tabulated the influence of temperature on the time required with various developers to attain a standard development factor or result, and knowing from trials the time change required for a temperature change of 10 deg. Centigrade (which is 18 deg. Fahr.), and which change is called the "temperature co-efficient," it is easy to draw up a table of times and temperatures for a given developer, so that if regard be paid to this table the impossible task of always developing at a standard temperature need not be attempted.

I think that I was the first to point out that this relation of time to temperature can be given in a graphic way by placing an even-division (arithmetic progression) temperature scale against a logarithmic-division (geometric progression) time scale; the even divisions being so spaced that the distance of 10 deg. Cent. (9 or 18 deg. Fahr.) is the same as the temperature co-efficient on the time scale, that is, from 1 to 1.9 for a large number of developers.

I applied this principle of movable adjacent scales to slide rule instruments for calculating times and temperatures, and I also applied it in my time thermometer for development, in which a logarithmic time scale is placed against the column of mercury, with the result that the mercury indicates times for development instead of temperatures, and all calculation for this one influence of temperature is saved.

But there remains the second influence, which Messrs. Hurter and Driffield explained, but did not tabulate or standardise, namely, that of the character of the plate itself, or, rather, of the sensitive film, some plates giving a desired result of density or contrast (development factor) in a much shorter time than others with the same developer, temperature, and time.

It is this influence of development speed of the plate itself that I deal with in this paper. I have for some years, in giving the exposure speed of the various brands of plates in the speed card issued by my firm, also indicated the development speed, and used such information in the instructions for my time thermometer. Mr. W. B. Ferguson, K.C., pointed out to me that I had never expounded fully the methods used in my testing laboratory for arriving at such speeds. Hence this article. The plates are exposed as for H. and D. tests, and the H. and D. chart used for noting the results.

Standards.

Temperature 60 deg. F. But as it is practically impossible to ensure this, the temperature of the room and developer is taken and the time variation necessary made by the thermo-calculator, as illustrated at the foot of fig. 1, or by the time thermometer.

Developer, metol-quinol, formula as in the Watkins Manual, 1 dram of each solution (Nos. 1 and 2) to each ounce of completed developer—no bromide. In practice No. 1 and No. 2 are made in one concentrated solution to 10 ounces, and 12 drams of this (which has a flocculent deposit) made up to 12 ounces of developer.

Contrast or Steepness of Result. A development factor of .9 in the H. and D. system. The theoretical steepness of 1.0, which Messrs. Hurter and Driffield stated to give the same contrast in the print as in original, was found to be too high.

Adopting the above standards, the test is to ascertain how many minutes' development are required to attain .9, the standard result. But in classifying the development speeds, I found it convenient to divide them into groups, and to give the speeds by letters for these groups. The central group taken was one which required 5 minutes to attain the stated result with the stated standards; this was called M (medium), and quicker developing plates were grouped as M.Q., Q., and V.Q., while slower ones as M.S., S., and V.S. The times for these groups must be in geometric proportion, and were decided upon by dividing a log. scale from 1 to 5 into six equal parts, also from 5 to 25 into six parts. The groups,

with their times in minutes (the central time for each group), are as below, temp. 60 deg. F.:—

V.V.Q.	V.Q.	Q.	M.Q.	M.	M.S.	S.	V.S.
1¾	2¼	3	3¾	5	6½	8½	11¼

For scientific purposes the development speed of the plate is the exact time required under the stated standards, and the group system was adopted for commercial reasons because I found it convenient to make the allowance for varying temperature by time, and the allowance for varying brands of plates by the dilution or concentration of developer, which concentration could be indicated best by group letters. My time thermometer is set to the M.S. (not the M.) group, viz., at 6½ minutes at 60 deg. F. This for practical reasons.

The calculating instrument shown in fig. 1 consists of three calculating scales or diagrams, each one for a separate purpose. the top (fan-shaped one) representing development factors; the middle one, temperatures; and the lowest one, the grouping of development speeds. The object in each case is to calculate the influence of time, and the one logarithmic time scale A is so mounted on a double slide B that not only has it a horizontal movement for calculation as hereafter described, but the carrier in which it slides moves vertically on the main body (brass plate) of the instrument, so that the time scale can be applied to any part. For reasons of space the full length of the slide is not illustrated.

Although the illustration, fig. 1, has no movement, most of the calculations can be done on it. For example, the grouping is shown set at 60 deg., the limits of M.S. group being from 5¾ to 7½. Suppose the temperature is not 60 deg., but 52 deg. Take the distance between these temperatures from the temperature scale on the edge of a slip of paper and at the same distance to the right of 5¾, and 7½ will be found the new limits for 52 deg., namely, 7½ and 10 minutes. In a similar way divisions and figures can be copied from the log. time scale on to the edge of a slip of paper and moved to any part of the diagram for calculating.

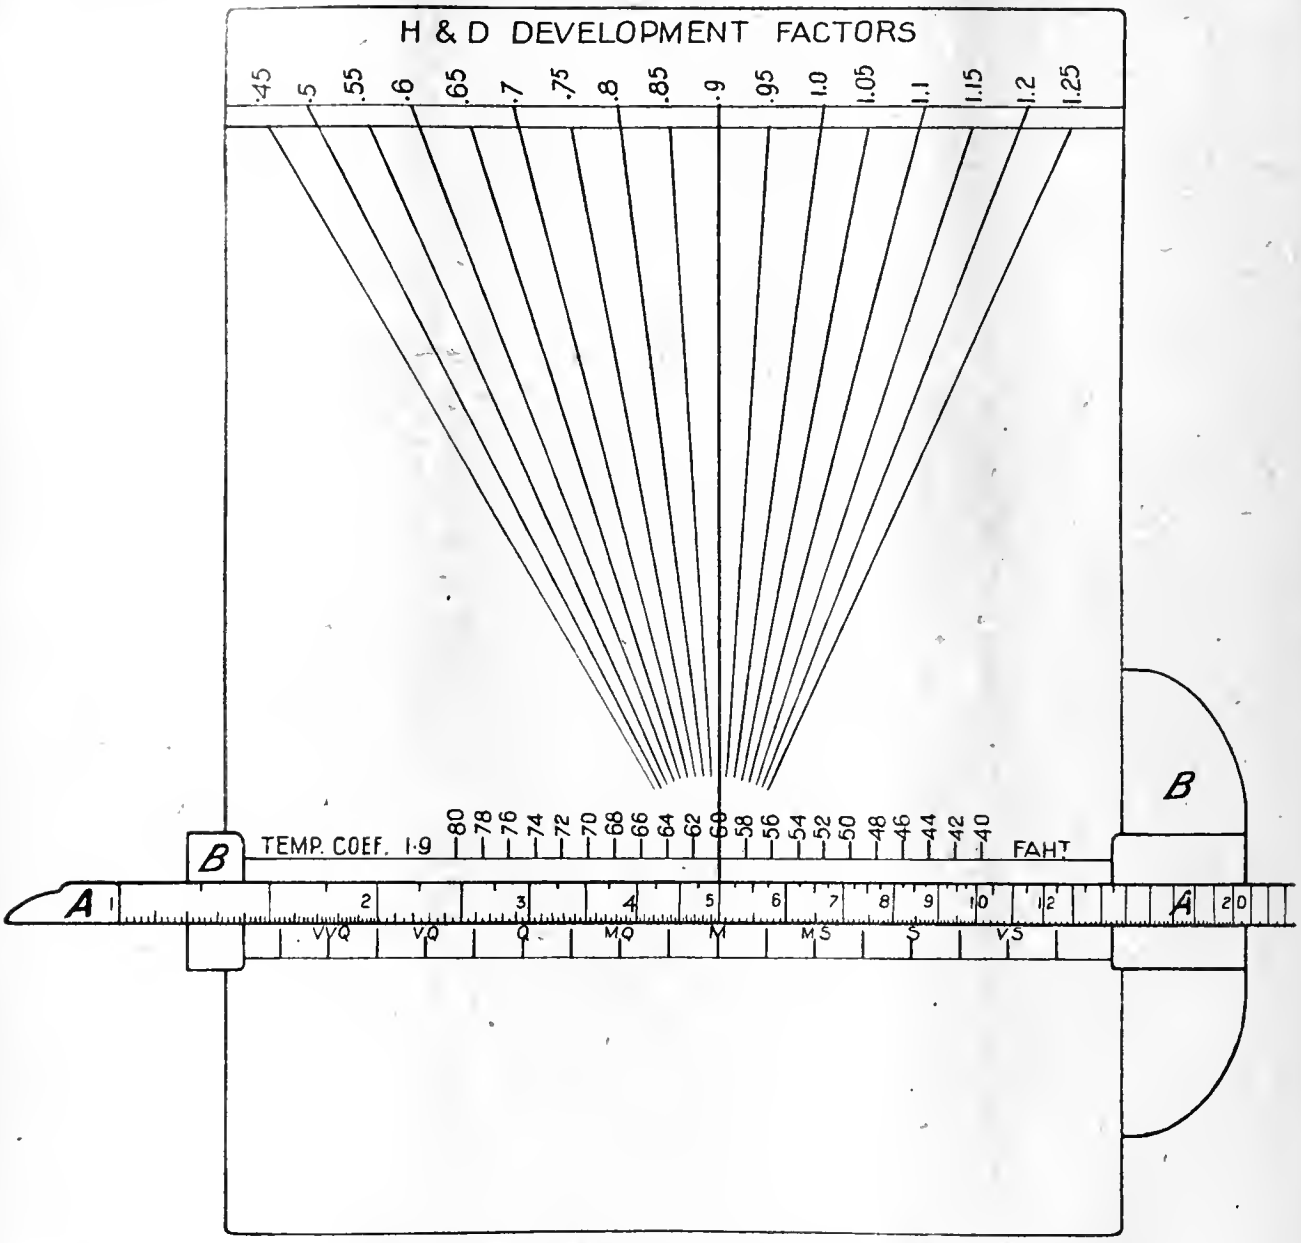

Fig. 1.—Instrument and scales for calculating development speeds.

Procedure.

Four different brands of plates (quarter plates, not strips) are exposed behind the revolving sector in the H. and D. exposing apparatus. They are developed in the tank illustrated in fig. 2, which permits each plate to be developed for four different times, the four times corresponding to four of the groups above described. The plates in the examples given

not being likely to be quicker in development speed than M., the groups from M. to V.S. were taken. If the temperature had been 60 deg. F., the trial development times would have been 5, 6½, 8½, and 11½ minutes. But as the temperature was 63 deg., the actual times are found by using the thermo-calculator part of the instrument illustrated in fig. 1, sliding up the log. slide until 5 minutes is against 60 deg. F., then against 63 deg. F. will be found 4½ minutes, which is right at that temperature for the M. group. The log. scale is therefore brought back to the lowest scale (letter groups), and 4½ is set to M. It is then found that the desired times for development (these being carefully set down in the nate book) are:—

M.	M.S.	S.	V.S.
4½	6	8	10½ minutes.

Now to develop the four quarter-plates set on edge lengthways in the tank (fig. 2), which is provided with an external spout into which developer can be poured when it rises from an aperture at the bottom of the tank. Twelve ozs. of standard developer is mixed up, and the aim is to pour in 3 ozs. at a time at such intervals that four strips of the plate are

Fig. 2.—Tank for development speed tests.

developed for the four different times indicated above. A table of times (starting from 0) at which to pour in must be set down as follows:—

Pour in first 3 ozs. at 0.
Pour in second 3 ozs. at 2½ (difference between 8 and 10½).
Pour in third 3 ozs. at 4½ (difference between 6 and 10½).
Pour in fourth 3 ozs. at 5½ (difference between 4½ and 10½).
Pour off at 10½ (longest time).

Each plate when fixed will have four strips across the H. and D. gradations developed for 4½, 6, 8, and 10½ minutes. Each developed strip has its gradations measured in a photometer and plotted out by the H. and D. method, which ascertains the inertia (used in giving the exposure speed of the plate) and the development factor required for the present test. In some cases a developed section, obviously too much or too little developed for the test, is not measured, to save time.

Now to ascertain from these results the exact time in minutes required to attain a steepness or D.F. (H. and D. method) of the standard .9. It occasionally happens that a strip shows exactly .9 in the measured result. But usually one developed strip is under and the next over the standard of .9.

The resulting factors in actual tests of the batch of four plates were as below:—

Group letter Minutes Developed	M 4½	M.S. 6	S 8	V.S. 10½	Development speed in minutes.
Plate A, development factors	.73	.92	1.06	—	5½
,, B, ,,	.62	.82	.94	1.02	7½
,, C, ,,	.62	.76	.88	1.0	8½
,, D, ,,	—	.65	.73	0.8	14

The final column gives the desired result—the minutes required for the standard result at 63 deg.

This result is ascertained from the data of the tests on the instrument illustrated in fig. 1 as follows:—

Plate A: Move the log. slide both horizontally and vertically over the fan-shaped diagram until 6 (minutes) on the log. slide coincides with .92 (2/5ths between the lines for .9 and for .95) at the same time 4½ (minutes) on the log. scale coincides with .73 (3/5ths between the lines for .7 and .75). Against the central line for .9 will be found on the log. scale 5½ minutes, the result. The results for plates B, C, and D are found in the same way, taking the M.S. and the S. results for B plates, and the S. and the V.S. results for C plate—that is, taking in each case a result on each side of the standard of .9 so as to ascertain on the log. scale the position of .9. Plate D illustrates a difficult type of plate, one which does not attain .9, and probably would not with longer development, as it increases in general density without increasing contrast before it gains .9. The 14 calculated result is therefore theoretical only. It would seem to be in a V.V.S. group, but I have not found it desirable to indicate such a group, but to advocate that with such plates development should cease as if in the V.S. group.

The above gives the result in figures, but, as I have explained, I prefer to give (for practical use) development speeds by dividing into lettered groups.

The limits of these groups (for a development at 60 deg.) is shown at the foot of fig. 1, the figures on the log. scale below the group letters being the centres of the groups, and those below the half-way divisions being the extreme limits of the groups. Thus (in the drawing) the central value of the M. group is 5 minutes, but anything from 4½ to 5½ minutes is within the M. group. But this is at 60 deg. F., and the trial I have detailed above was at 63 deg., the central time for M. being 4½ minutes. Set, therefore, M. to 4½, and then it can be seen at once within which group the results of the above trials come.

Plate A, result 5½, comes within the M.S. group.
,, B, ,, 7½, ,, ,, S. ,,
,, C, ,, 8½, ,, ,, S. ,,
,, D, ,, 14, comes outside the V.S. group, but for practical purposes is classed as V.S.

If the development speed is to be given in figures, not groups, the above figures, which are those resulting from the 63 deg. test, must be adjusted for 60 deg. To do this set the 63 deg. figure on the log scale to 63 on the temperature scale, and then against 60 deg. will be found the desired development speed at 60 deg., viz., A, 6½; B, 8; C, 9½.

There are probably some small theoretical errors in these graphic methods of ascertaining development speeds, but I feel that they are too small to falsify the result. In practice I (or now my assistant) do not use the thermo-calculator part of fig. 1, but simply dip the time thermometer in the developer, which (being set at 6½ minutes for 60 deg.) at once indicates the right number of minutes for the M.S. group at the temperature prevailing.

The tests given were a batch of rapid plates which were guessed to be slow developers. A batch of slow or process plates would be tested for V.Q., Q., M.Q., and M. times, and a batch of medium-type and ortho. plates as if from Q to M.S.

ALFRED WATKINS.

THE H. AND D. DOCTRINE.

In the preceding chapter the law of the production of a theoretically perfect negative has been considered in reference first to the time of exposure. That law is that the difference between any two of a series of densities is *proportional* to the difference between the logs of the producing exposures.

Correct exposure thus lays the basis for the making of the theoretically perfect negative, in which the difference between each pair of a series of densities is *equal* to the difference between the logs of the corresponding exposures.

By experiment it is found that this exposure law operates only when a plate is exposed for a longer time than will give some kind of a negative; also, that the law ceases to operate when the plate is exposed for longer than a certain time.

By plotting the densities against the log exposures the range of exposures over which the plate behaves in accordance with the law is shown by the straight line part of the resulting curve.

This straight line portion shows the latitude of the plate and also—when the range of light-intensities in the subject is approximately known—the latitude in exposure.

But correct exposure, as shown by the straight line part of the curve, is only one stage towards correct reproduction of the tones of the subject in negative form.

It shows that the differences between successive pairs of densities are equal to one another, *i.e.*, proportional but not necessarily equal to the difference between the logs of the corresponding exposures where these exposures proceed by a common factor.

Since, however, the whole series of densities are *proportionately* increased as development is continued, the common difference is similarly increased, and hence at a "correct" stage of development the negative corresponds with theoretical requirements.

Development may be carried short of or beyond this point as required by the subject or printing paper.

Consideration of development from this standpoint in the present chapter is concerned chiefly with the contrast or gamma of a negative, from which it will be seen that contrast in a negative is related, on the one hand, to the contrast in the subject, and, on the other hand, to the contrast properties of printing papers.

III. *(continued from p. 375).*—DEVELOPMENT AND THE REPRODUCTION OF CONTRAST.

Gamma and the Printing Paper.

It will have been evident from the foregoing that so long as we limit ourselves to regarding negatives as records, in inverted light and shade, of subjects which are within the latitude of the plate, every negative should be developed to a gamma of 1.0 in order to be theoretically perfect. Then the light-intensities transmitted by its various parts are inversely proportional to the light-intensities emitted by the corresponding parts of the subject.

But this view of the theoretically perfect negative leaves out of consideration the different methods by which prints are made—on papers of very different character, and by enlarging as well as by contact printing. For reasons connected with the properties of printing media, the gamma of a negative requires to be less than 1 in some cases and greater than 1 in others in order to reproduce the light-intensities from the subject correctly—or rather as correctly as possible—in the prints. The useful range of gamma for this purpose is from about 0.8 (low) to about 1.5 (high). The relation of the value which the gamma of a negative requires to bear to a printing process may now be briefly outlined. The reader will see that it is simply a numerical rating of the proportionately greater or less contrast which the negative requires to have according to the lesser or greater contrast properties possessed by the printing paper.

In the respect we are now considering, we may, for the sake of simplicity, look upon printing papers as differing in what may be called their "exposure range"; that is to say, the number of exposure units which are necessary to produce the blackest deposit which the paper will yield when the faintest visible deposit is produced by one unit. This is not by any means an adequate description of the property of a printing paper, but it will serve to display the effect of the gamma of the negative. Let us assume, what is about correct as far as it goes, that a contrasty gaslight paper has a range of 10 : 1, and a bromide paper one of 50 : 1. For practical purposes this may be expressed:—

	Exposure in seconds to produce faintest visible deposit.	strongest black.
Gaslight paper	1	10
Bromide paper	1	50

If now we have a theoretically perfect negative of a subject having a scale of light-intensities from 20 to 1 the light-intensities transmitted through the heaviest and lightest deposits are relatively 1/20 and 1/1 (gamma = 1).

In printing on the gaslight paper, an exposure which just produces the full black image through the lightest deposits (the shadows) of the negative does not transmit enough light through the heaviest deposit—only 1/20 instead of the 1/10 which the paper requires. Hence under-exposure in the high-light parts of the print.

In printing on the bromide paper, the exposure which just produces the full black image through the lightest deposits transmits too much light through the heaviest shadows—1/20 instead of 1/50, which is all the paper requires. Hence over-exposure in the high-light parts of the print.

The reader may trace for himself the opposite effects if we expose the printing paper correctly for the high-lights.

It is plain that for the best results we require not a theoretically perfect negative (gamma = 1), but a flatter negative (gamma less than 1) for the gaslight paper, and a more contrasty negative (gamma greater than 1) for the bromide paper.

But how much less and how much greater must the gamma be? An exceedingly simple calculation serves to find the value which the gamma requires to have.

We have seen that

$$\text{gamma is } \frac{\text{difference of densities.}}{\text{difference of log exposures producing them.}}$$

$$i.e.\ \frac{D_2 - D_1}{\log E_2 - \log E_1}$$

This formula applies to any pair of densities (recorded in the straight-line curve) and their corresponding log exposures. In our case of a 20 : 1 subject we are dealing with the extremes of each.

Exposures are (relatively) 20 1

Therefore log exposures are 1.3 0

As regards the densities in the formula, for gaslight paper we require the transmissions corresponding with the extremes of our 20 : 1 subject to be 1/10 : 1; that is to say, the opacities to be 10 : 1.

The densities, therefore, require to be log 10 and log 1

So the required gamma is

$$\frac{\log 10 - \log 1}{\log 20 - \log 1} = \frac{1 - 0}{1.3 - 0} = .77$$

Similarly for the bromide paper, the extreme transmissions of the negative require to be 1/50 : 1/1, and the opacities 50 : 1. The densities, therefore, are log 50 and log 1, that is 1.7 and 0, and the required gamma is

$$\frac{\log 50 - \log 1}{\log 20 - \log 1} = \frac{1.7}{1.3} = 1.3$$

If we call the range of light-intensities in the subject x:1 and the exposure range of printing paper y:1, then, generally, the gamma necessary for the negative of a subject of extreme light-intensities x:1 (if recordable on the straight-line curve) which is to be printed on a paper of exposure range y:1 is $\frac{\log y}{\log x}$ If the gamma has this value, the negative is one which (1) best fits the exposure range of the printing paper, and (2) at the same time yields a print correctly representing the tones of the original subject. The second of these results is obtained only if the paper produces densities proportional to log exposures over a sufficient range. This condition is not fully realised in practice, but the behaviour of papers in this respect would lead us too far from our present subject.

To digress, however, for the moment, to a side-issue from the gamma of a negative. If we know nothing about the range of light-intensities from the subject which a negative represents, but are concerned only in finding a measure of the suitability of a negative for a given printing paper, that measure is supplied by the difference between the highest and lowest densities. That this is so will be obvious from the following:—

Densities, say	1.90	.3
Difference of densities	1.60	

Since density is the log of opacity, a difference of two densities represents the ratio of the corresponding opacities. Therefore, since 1.60 is log 40.

ratio of opacities is	40	1

that is to say, the negative is a little flatter than one best suited to bromide paper of exposure range 1:50. This value (difference of maximum and minimum densities) is, thus a measure of intrinsic contrast in any negative whatever, whilst gamma is a measure of contrast in a negative in respect to correct reproduction of the tones of a subject. Providing that a negative has been correctly exposed the difference between minimum and maximum densities (which is the log of the ratio of the corresponding opacities) tells us what printing range of paper is necessary for correct reproduction of a subject once the negative has been developed to an unknown degree. Hence, if a correctly exposed negative representing an unknown range of light-intensities is just correctly printed on a certain paper, the range of light-intensities in the subject is equal to the exposure range of the paper, that is to say, when the full scale of the paper is used. This follows from the relation we have already seen, viz., that the gamma necessary for the negative of subject range x:1 (if recordable on the straight line curve) to be used with a printing paper of exposure range y:1 is $\frac{\log y}{\log x}$ An example will illustrate. Imagine negatives of subject range 1:20 developed to gammas respectively less than, equal to, or greater than 1.0, *e.g.*:

Subject Range, 1:20.

	Gamma	Range of opacity
(1)	.77	1:10
(2)	1.0	1:20
(3)	1.6	1:100

But for a negative (of a subject of unknown range) of $\gamma = .77$,

I. printed correctly on a paper of range:—	II. the corresponding subject range is:—
1:10	1:20
1:20	1:50
1:100	1:400

The figures in Col. II. follow from the relation:

$$\text{necessary gamma} = \frac{\log \text{printing range}}{\log \text{subject range}}$$

whence $\log \text{subject range} = \frac{\log \text{printing range}}{\text{gamma}}$

Similarly, for a negative of $\gamma = 1.6$,

I. printed correctly on a paper of range:—	II. the corresponding subject range is:—
1:10	1:4.3
1:20	1:6.5
1:100	1:20.0

In the case of a negative of gamma = 1.0, it is obvious that the range of the paper is equal to that of the light-intensities.

Thus the practical significance of the difference between maximum and minimum densities (= log opacity ratio) in a negative is best appreciated by looking upon it as the gamma of a negative of a subject range equal to the exposure range of the paper on which the gradation of the negative is fully nd correctly recorded. In other words $D_{Max.} - D_{Min.}$ indicates the contrast quality of printing paper required by the negative and, if that quality is known in definite figures, the range of the tones in the subject.

Gamma, on the other hand is a measure of contrast in known relation to the subject and by calculated time of development can be obtained larger or smaller, as required by the printing paper.

The Gamma of a Plate.

So far gamma has been referred to as a measure of the contrast of the negative relatively to that of the subject, but it is used in another way, viz., as a measure of the ability of a plate to yield negatives of intrinsic contrast. It is necessary to consider this property in a few words before dealing with the calculation of the time of development required to produce a negative of given gamma.

As we have seen, the longer development is continued within certain limits, the greater the value of gamma becomes. In practical language the contrast or vigour of a negative increases with the time of development. But the rate of increase in the growth of gamma becomes slower as development proceeds, so that after a time no further appreciable increase in gamma takes place. This maximum producible gamma is a characteristic quality of the plate. As it is produced by a period of development which theoretically is infinitely long, the gamma produced under these conditions is denoted as gamma ∞ (gamma $_{\infty}$). But it is not necessary that development should be enormously prolonged in order to obtain a value for gamma sufficiently near to that which theoretically would be obtained by development for an infinite time. In the development of a plate, according to a calculation of Ostwald's, quoted by Dr. Mees, about seven times the period necessary for half the process is long enough to make the action within 1 per cent. of theoretical completion.

But in the actual practical measurement of gamma it is not necessary, nor indeed accurate, to develop for an abnormal time. Although plate-makers attach great importance to gamma as a measure of the quality of a plate, they are able to calculate its value from lower gammas (and other properties) which are more accurately determined owing to the lesser densities involved.

G. E. B.

(To be continued.)

Advertise Your Business.—A little varnishing and retouching of yourself and your business is excusable; nay, necessary in presenting your merit to the public. Photography is still a bit of occult science (says the Philadelphian "Bulletin of Photography"), and requires some little ostentation and assumed gravity in the profession. A plain unostentatious background is not always the best setting to personal merit. There is demanded to set it off to advantage a few blazonings or touches. No man's merit can be fairly gauged if he is not known, and how can he be known or appreciated if he recedes entirely in the background? We are commanded to put our light in a candle stick and not under a bushel, that it may be seen of men. A great name in art goes but a very little way, and is chilled as it creeps along the ground surface of the world unless it gets something to revive it. If you don't let the public know about you—that is, advertise yourself—the public won't trouble itself to hunt your greatness out.

THE TREND OF PHOTOGRAPHIC PRINTING.

A COMPARISON of modern printing methods again proves the overwhelming predominance in the use of papers of the bromide and gaslight type, and although I am an ardent supporter of development papers and believe them to be capable of producing very beautiful results, I feel regret that the daylight printing processes should be so sadly neglected and, to many modern printers, not properly understood.

In these times of rush, competition, and mass production, photographers must perforce adopt the method of printing that gives the best business results, and therefore the trend is, and always will be, towards papers of the development type that can be exposed by artificial light. Manufacturers are showing great energy in producing new development papers in various grades to suit the professional photographer, trade printer, and amateur, and I have ample evidence that papers of the gaslight type will eventually oust bromide papers from their exalted position. In America, bromide paper is used for enlarging but seldom for contact printing, whilst gaslight and slow development papers are used almost exclusively for contact work, a state of things that will obtain here in the near future.

The reason for this change to slow development papers is not that it is a vogue or fashion, but is caused by the demand of the modern professional workers for a paper that will give results equal to a print-out paper, but without the drawbacks of daylight printing. Many of our leading photographers are now turning out as a matter of daily routine magnificent prints on the slow development papers, mostly of the warm-black type, with the long scale of gradation that makes the most of a well exposed and fairly plucky negative.

The excellence of modern development papers and the ease with which they are worked tends to make some printers careless, and this can be confirmed by making a comparison of work done by two different workers on paper of the same make. One may produce results such as our leading professionals obtain, the prints being of a quality almost equal to the finest carbon or platinum prints, whilst the other worker will show third-rate results. Without going into the subject of suitable negatives (beyond a personal opinion that the bulk of portrait negatives are under-exposed), why is it that one man can get better results than another on the same make of paper? I have frequently heard of photographers who swear *by* a particular make of paper, and others who swear *at* the same make. Yes, even photographers have been known to emulate the golfing enthusiast! Personally, I think it is all a matter of proper instruction in the handling of the papers. How many printers read and carry out the instructions sent with the papers? Very few indeed, I am afraid, but even this is not the key to success. The personal element comes into play, and a specialised knowledge of the process gives one man a pull over another. A careful and close study of negative gradation and its characteristic rendering by the different grades of paper is all important. In my experience as a teacher of professional-printing I find that many would-be printers have a very vague notion as to what constitutes a "good" negative, and what paper will be best suited to it. It has been said that the "printers' dream" is of negatives which never vary as to density and gradation; but, alas! it is only a dream. Even in the best appointed studios there are various factors that make for results of varying characters.

After all that has been written in this Journal and all that has been published by the manufacturers as to the best paper to suit a particular type of negative, there are still printers who are hankering after the impossible, viz., a paper that will give perfect prints at will from "ghosts" and "soot and whitewash." A little study of relative gradation of different negatives, and the colour of the deposit, will well repay any printer who wishes to be thoroughly *au fait* with his work. This, with a knowledge of the scale of gradation the different grades of papers possess, should enable the printer quickly and accurately to sort his negatives for printing. The very descriptions of the various grades of slow development papers are a stumbling block to some printers, and a great deal of misunderstanding exists as to the meaning of soft, normal, vigorous and contrasty. A soft paper does not necessarily mean that only soft results can be obtained on it, because it is quite easy to obtain prints of rich quality from "good" negatives. Most of the high-class professionals use the soft grade of paper. The vigorous or "contrasty" paper would not give good results from a vigorous negative, and is made solely for printing "ghosts" and negatives of poor contrasts. The terms used by the manufacturers refer to the scale of gradation possessed by the particular grade, and it is, I think, an excellent practice, because it gives the printer the knowledge as to which grade will best render the gradations of the negative, or, further, which grade will be suitable to falsify the gradation of the negative, should this be necessary. To print on a vigorous paper from a "ghost" can be classed as a deliberate falsification of the gradations of the negative in order to obtain good results.

The warm-black or green-black colour by direct development is quite a feature nowadays, and many printers produce beautiful results, the success of which is due first to the good quality of the negatives, and secondly to the intelligent use of a restrained and diluted developer. The exposures are always on the full side; indeed, some two to six times the normal exposure is given to obtain special colours, but if the prints are required for sepia toning the procedure is usually different. A correct exposure, correctly followed by full development of all light action, gives the best type of print for toning.

One of the many advantages of these slow development papers is the comfort in working—a dark-room that is no longer dark, but illuminated by strong yellow light by which the depth of the image can be judged to a nicety. The correct depth of the image on the slow papers is judged by visual examination by reflected light, and is not arrived at by development to time.

Bromide paper is necessary for enlarging, and may eventually be used solely for that purpose, and by printers who live in remote country districts where gas or electric light cannot be obtained. The gaslight type of paper has come to stay, and this fact should be borne in mind by photographers who are fitting up new premises, and all prints by contact should be made in a brightly lit printing-room, and not in a very dark dark-room.

There are, however, many of us who still admire the pearly whites that nothing but platinum will produce, or the rich carbons of exquisite gradations and colour. It is true that these processes are in daily use by some photographers, but they are greatly in the minority. The platinum process is considered quite simple to work, yet (as most photographers have probably found) good platinum printers are very hard to get, and a man who can produce regularly good sepia platinum prints with small waste is "some" printer. Carbon printing calls for considerable skill in dealing successfully with the variety of everyday work. Old methods die hard, and there are photographers who are still printing portraits in P.O.P. glazed and embossed. Speaking to one of these workers recently, he assured me that his sitters preferred P.O.P. to any other process, and did not mind waiting for delivery. The combined toning and fixing bath considerably simplifies the handling of P.O.P., but the results are of doubtful permanence, and the colour inferior to that obtained by separate baths. It is a severe test of a printer's skill to produce daily batches of perfectly toned P.O.P's., and calls for the greatest cleanliness and judgment.

The self-toning papers are very popular amongst amateurs, and are gaining popularity in professional studios. The

collodion self-toning papers give particularly fine results, and now that manufacturers are making these in a variety of surface and colour of base the demand is sure to increase. There seems to be some doubt amongst certain photographers as to the permanence of self-toning papers, but I cannot see why they should not be as permanent as any other silver print, if properly fixed. I have prints which were made over ten years ago (on Paget and Seltona), and they are as perfect as they were when made. Two essentials in the use of self-toning papers are (*a*) an alkaline fixing bath, (*b*) dry-mounting with adhesive tissue.

In conclusion, there is one point I would like to emphasise, and that is to impress upon photographers the absolute necessity of giving their assistants proper instructions and training in the working of the printing papers used, particularly in bromide and slow-development papers, as there is an unfortunate tendency to regard these papers as so simple to work that a junior assistant is expected to produce the prints without training.

R. R. Rawkins.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications June 13 to 18.

Processes.—No. 16,626. Photographic processes. D. E. Batty and S. Whyte.

Finders.—No. 16,276. Range finders and focussing-devices for photographic cameras. H. G. H. Embrey.

Shutters.—No. 16,695. Locking device for triggers of photographic shutters. F. B. and H. J. Holmes-Higgin.

Cameras.—No. 16,766. Photographic cameras. G. Waterlow.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Colour Cinematography. No. 156,980 (December 11, 1919).—The invention consists in a system of additive colour cinematographic projection in which several negatives are made simultaneously and are similarly deformed side by side upon each unit area of the film, the projecting system causing an inverse deformation which reconstructs the final projected picture in correct proportions. Edward Constant Southwarth Parker, c/o Navy Department, Washington, U.S. (Owing to the number of drawings illustrating the details in the specification the latter is transferred to another page of this issue in the "Colour Photography" Supplement.)

Submersible Cameras. No. 161,730 (February 21, 1920).—The camera comprises a hermetically closed case having one or more chambers each designed to contain a camera, the lens of which is positioned adjacent to, and preferably almost flush against, an optical flat fitted in the wall of the case and the shutter of which is controlled from the surface by electrical means. The case is also furnished with one or more powerful electric lights for illuminating the objects to be photographed, and means may be provided for adjusting the positions of the camera or cameras and the illuminant in order that the camera, when submerged, can photograph objects at any desired angle.

A suitable construction of apparatus comprises a case composed of three superposed castings, preferably of gun-metal, of which the central casting is displaced at an angle of 45 deg. to the top and bottom castings. Each of these castings, is provided with four symmetrically disposed chambers within each of which is fitted a mercury vapour lamp, and the central casting is, in addition, furnished with four separate chambers between the lamp chambers for the reception of the cameras, the shutters of which are electrically operated as above described. The camera cases are provided with removable doors for enabling access to be had to the interior for any purpose and with optical flats adjacent to which the camera lenses are placed as stated above.

Each lamp chamber is fitted with a water-tight lens for the projection of the light-beam and also with a packing gland for the cable which conveys current to the lamp, all the cables being connected to main leads in a common terminal box provided on the top of the upper casting. Furthermore, means may be provided for tilting each of the lamps.

In practice the apparatus is advantageously lowered by a pair of weight-bearing cables running over separate pulleys in order to prevent undue oscillation and the current supply cable is mounted on an independent winding gear.

When the apparatus is used in mine shafts it may be so placed that a complete circle of exposure may be made simultaneously, and this can take place successively at different depths, in order that such a succession of exposure may be obtained without the necessity of bringing the apparatus to the surface between each operation, the cameras may be fitted with mechanism by which the plates are changed automatically after each exposure.—Robert Henry Davis, of Siebe, Gorman and Co., Ltd., 187, Westminster Bridge Road, London

The following complete specifications are open to public inspection before acceptance :—

Apparatus.—No. 164,708. Apparatus for cleaning films. Meester-Film Ges

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Kinatome.—No. 413,806. Cinematograph projection apparatus. Herbert George Ponting, 47, Oxford Mansions, Oxford Circus, London, W.1, company director. March 30, 1921.

Desium.—No. 414,023. Light-filters for cinematograph projectors. David Kennedy, 215, Selhurst Road, South Norwood, London, S.E.25, manufacturer. April 6, 1921.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

The Amateur Photographer and Photography (title design).—A periodical publication. Iliffe and Sons, Ltd., 19, Hertford Street, Coventry, publishers.

Luxor.—No. 412,700. Photographic lenses. Taylor, Taylor & Hobson, Ltd., Stoughton Street Works, Stoughton Street, Leicester, scientific instrument makers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, July 4.

South London Phot. Soc. "Further Chat on Pictorial Photography." S. Bridgen.

Tuesday, July 5.

Manchester Amateur Phot. Soc. "A Talk on Soft-Focus Lenses." H. N. Holland.

Thursday, July 7.

Hammersmith (Hampshire House) P.S. "Composition." M. O. Dell.

Saturday, July 9

Bradford Phot. Soc. Excursion to Marley and Druids' Altar.
City of London and Cripplegate P.S. Outing to Hook.
Manchester Amateur Phot. Soc. Ramble to Birtles and Redes Mere.
South London Phot. Soc. Excursion—Watford to Brickett Wood.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution, by mutual consent, of the partnership between Edward Lawford Hughes and Ernest Vernon Howell, carrying on business as dealers in pleasure craft, including the sale of photographic requisites, etc., at Horning, Norfolk, under the style of Hughes and Howell.

NEW COMPANIES.

HOOPER STORE CHEMISTS (LYNTON), LTD.—This private company was registered on June 7, with a capital of £700 in £1 shares. Objects: To deal in patent and proprietary articles, photographic apparatus, etc. The first directors are:—Mrs. B. Hooper, Fairmead, Lynton, N. Devon; T. Luke, Stourton House, Lynton, N. Devon. Qualification: 10 shares. Secretary: W. J. Hooper. Registered office: Churchill, Lynton, N. Devon.

A. J. RAWLING, LTD.—This private company was registered on June 20 with a capital of £2,500 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in photographic apparatus, meteorological instruments, etc. The first directors are: A. J. Rawling, 7, Lennard Road, Croydon; J. W. Timmis, 79, Waddon Park Avenue, Croydon; D. O. Rawling, 7, Lennard Road, Croydon. Registered office: 8, High Street, Croydon.

J. R. HOWARD, LTD.—This private company was registered on June 6, with a a capital of £2,000 in £1 shares. Objects: To carry on the business of manufacturers, exporters and importers of and dealers in optical, astronomical and scientific goods, lens, microscopes, etc. The subscribers (each with one share) are:—J. R. Howard, 41, Wigmore Street, W.1, optician; R. J. Howard, 46, Normanby Road, Dollis Hill, N.W.10, optician. The first directors are not named. Registered office: 41, Wigmore Street, W.1.

WRENCH, LTD.—This private company was registered on June 7 with a capital of £1,000 in £1 shares (500 preference). Objects: To carry on the business of opticians, photographic dealers, etc. The subscribers (each with one share) are: F. W. Wrench, 12a, Carlton Road, Bournemouth, pharmaceutical chemist; Miss R. S. Osmond, 15, Florence Road, Boscombe; C. H. Osmond is the first director. Qualification: £100. Remuneration as fixed by the company. Secretary: Miss Robina S. Osmond. Solicitor: F. A. Johns, 375, Holdenhurst Road, Bournemouth.

B. NORTON, LTD.—This private company was registered on June 21 with a capital of £100 in £1 shares. Objects: To take over the business of a pharmacy and drug store proprietor carried on by B. Norton at 219, Harehills Lane, Parade, Leeds, and to carry on the business of chemists, druggists, manufacturers of and dealers in proprietary articles, chemical, photographic, scientific apparatus and materials, etc. The first directors are: B. Norton (managing director and chairman), 219, Harehills Lane, Leeds; Lily Norton, 219, Harehills Lane, Leeds; R. H. Norton, 219, Harehills Lane, Leeds; J. Punch, 38, Seaforth Place, Leeds. Registered office: 219, Harehills Lane, Leeds.

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

News and Notes.

THE R.P.S. WORKROOMS.—A charge is to be made for the use of the Royal Photographic Society's enlarging and dark-rooms, the proceeds to be devoted to the cost of the renewal of equipment and improvements of these facilities.

THE ABNEY MEMORIAL LECTURE.—The memorial lecture on the life and work of the late Sir William Abney, given by Mr. Chapman Jones before the Royal Photographic Society on April 26 last, is published *in extenso* in the July issue of the "Photographic Journal," copies of which may be obtained from the publishers, Messrs. Harrison & Sons, Ltd., St. Martin's Lane, W.C.2, price 2s. 6d., postage extra.

THE R.P.S. EXHIBITION.—Entry forms and all particulars of the 1921 Exhibition of the Royal Photographic Society are now ready, and may be obtained from the Secretary, 35, Russell Square, W.C.1. Exhibits delivered by hand must be presented, unpacked, on or before August 27, but those sent by carrier must reach the Society on or before August 26. The private view is to be on Saturday, September 17, from 2.30 p.m. till 5 p.m., the exhibition opening to the public on Monday, September 19, and remaining open daily, Sundays excepted, from 11 a.m. till 9 p.m., for six weeks.

PHOTOGRAPHY IN ADVERTISING.—We learn from the American journals that the principals of one of the largest firms of clock manufacturers in the United States are giving a prize of $250 for the best photographic illustration of one of their clocks in a still life composition. The prize is to be awarded at the Buffalo Convention, July 18 to 23, 1921. A representative of the company will be at Buffalo with a cheque to hand the winner when the award is announced. The photographs are to be judged for their photographic merit, for their advertising and reproducing value, and for their artistic quality.

METAL DUST MARKING PRINTS.—A writer in "Work" states that the finely powdered metals as used for decorative purposes and on mounts are dangerous things to have near silver prints, as any of the metallic dust remaining long in contact with the print is sure to leave a mark. This does not apply to gold itself, but to "Dutch metal" and similar gold substitutes. For this reason photographic mounts which are to be "blocked" with gold should be obtained from a firm on whom dependence can be placed. Photographers may also be cautioned against keeping fancy mounts near their stock of sensitive paper. Metallic dust falls from such and penetrates into unopened packets of sensitised paper and spoils it.

THE PATIENT PHOTOGRAPHER.—Mr. F. M. Sutcliffe states in the weekly edition of the "Yorkshire Post" that he once saw two photographers weather bound, waiting for the rain to stop to make a picture of a fine subject. They had waited all the morning and all the afternoon. At five o'clock one said, "If we are to catch the train—the last one—we must be off at once." The other said, "You can go if you like, but I am going to wait even if I stay here all night, and sleep in that barn." The photographer who stayed was rewarded about an hour later with the most glorious sunset sky behind his subject it is possible to imagine. That he nearly cracked his skull the next morning against the roof of the loft in which he slept is neither here nor there.

PHOTOGRAPHERS' ASSOCIATION OF THE PACIFIC NORTH-WEST.—The sixteenth annual convention and exhibition of this Association will be held in Vancouver, B.C., from August 2 to 5, inclusive. The secretary-treasurer (Mr. A. T. Bridgman, 413, Granville Street, Vancouver), sends us a considerable amount of literary matter, telling what is to take place at the forthcoming meeting, with a letter in which he says: "We are particularly anxious to have our exhibition this year on a much wider scope than heretofore, and so take the liberty of asking you for your co-operation in bringing this matter before the photographers of the United Kingdom. We require not more than eight pictures not larger than 11 x 14, mounted, but not framed. Each exhibitor will receive special mention, and his exhibit will be decorated with his name and city, as well as the country to which he belongs. He will be sent all press notices referring to the exhibition, and if he so desires we will ship

his pictures back to him without cost, and securely packed. There is no entry fee, and special care will be taken of all pictures entered in the British exhibit. We expect to have displays from all parts of the British Empire, especially Australasia, and we do not want the Mother Country to be neglected."

PROTECTION FROM X-RAYS.—The preliminary report of the Special Committee of Radiologists which was appointed to consider the question of protection against X rays has been published, and the "Times" of Friday last dealt very fully with the matter. We learn from the report that ventilation is regarded as being of very great, even of supreme, importance. The X-ray room should not be below ground level. Artificial ventilation is necessary in most instances, for, with very high potentials, so-called coronal discharges are difficult to avoid, and these produce ozone and nitrous fumes, both of which are prejudicial to the operator. Dark-rooms should be capable of being opened up to sunshine and fresh air when not in use. The walls and ceilings of these rooms "are best painted some more cheerful hue than black."

THE FOX TALBOT CAMERAS.—A writer in the "Westminster Gazette," referring to the visit of the Convention to Lacock Abbey and the exhibition of its treasures, says: "I called attention to this photographic apparatus in these columns about two years ago, and suggested that it might be acquired for the nation. Arrangements have now been practically completed, I understand, by which the more interesting items will be placed in the museum of the Royal Photographic Society. Full justice has never been rendered to the work of Fox Talbot. He is distinguished among all the early research workers in photography by the fact that he invented the process upon which all later photography has been built up. The process of Daguerre was barren; it had no progeny. It produced with a single exposure one positive image. Fox Talbot made negatives from which any number of positives could be obtained. The large collection of early cameras which he possessed is due to the fact that he was working when very long exposures were required. In his earliest paper upon "Photogenic Drawing" he describes his practice of setting up a number of cameras taking a scene from different view-points, and evidently contemplated that such would continue to be the practice. He did not foresee the time when a boy with a hand-camera, giving exposures of a fraction of a second might move from point to point and exhaust his supply of plates in less time than it would take to impress one of Fox Talbot's "drawings" on a sheet of paper.

MICROPHOTOGRAPHY.

To the Editors.

Gentlemen,—May I be allowed to question the statement made by your correspondent, W. T. L., in your issue of 17th inst., that the late Mr. J. I. Pigg reduced a page of the "British Journal" down to one thirty-second of an inch, "and every letter in this miniature reproduction could be read distinctly under the microscope." Unless it was an advertisement page having only specially large type, that does not seem to me to be possible. Your pages are 7½ ins. × 9¾ ins.; if the width were reduced to one thirty-second inch, the reduction would be about 230 times. The thick strokes of your present type do not exceed 1/80 inch, consequently a 230 times reduction would bring their width down to 1/18400 inch.

By means of my own process of Grainless Photography the finest lines I have been able to produce have been about 1/12500 inch, but these were contact prints from diamond scratches; by photographic reduction using short focus Zeiss micro-planar lenses, I have been unable to secure lines of less than 1/6000 or 1/7000 inch width. With a wet collodion process, in which the plate shows grain, however fine, I much doubt whether lines exceeding, or even as fine as 1/5000 inch could be secured.

If I am mistaken, and your correspondent could say where any finer line reductions than this, by the wet collodion process, can be seen, it would be very interesting.—Yours faithfully,

JULIUS RHEINBERG.

ADVERTISED ELECTRICAL APPARATUS.

To the Editors.

Gentlemen,—I have noticed repeatedly, nearly all advertisers, when offering electric apparatus for sale in the "B.J.," invariably omit to state the voltage for which the lamps are made, and in the case of arc and mercury vapour lamps, whether for alternating or continuous current.

I feel sure if they did this it would save correspondence and trouble, and prevent purchasers buying lamps unsuitable, and in some cases useless for the current supplied by the Electric Company in their town or district.—Yours faithfully,

ALEXANDER CORBETT.

48, Baker Street, London, W.1.

THE WOMAN IN PHOTOGRAPHY.

To the Editors.

Gentlemen,—From time to time I have been very highly tickled by some of the letters appearing in the "B.J.," but the letters under above heading are really the funniest of all, especially the one appearing in the issue dated June 3, from "The Woman in Photography."

The confessions of this lady give the whole show away, and prove conclusively that she has no right to be in our ranks. How can she look after her big house as she should if she attends to her studio properly? Perhaps the poor "one little maid" has to do the whole housework, from front steps to back door. And what about hubby? Surely he can keep the "home fires burning" and have his wife in her proper place at home, and not have her keeping a man photographer out of a job! And, finally, how was it possible for a group of footballers (a team, I take it) to win a cup "from a good many teams"? A cup can only be held by one team for a season. I can understand a team beating a good many teams in winning a cup.—Yours truly,

A MAN IN PHOTOGRAPHY.

To the Editors.

Gentlemen,—My first experience of photography was being taken at the age of 7 in 1854. In 1857 a Mrs. Atkinson came into the town with a caravan, and made some very good glass positives, and those she took of my mother have often been admired quite recently.

Photography as a profession does not date back very much further than 1857, so this is a clear proof that women photographers have been in existence for quite a long time. Mrs. Atkinson was the operator, there being no Mr. Atkinson about.—Yours faithfully,

W. T. WILKINSON.

Birmingham.

STEREOSCOPIC LENS SEPARATION FOR NEAR OBJECTS.

To the Editors.

Gentlemen,—Referring to the article by E. J. Bedford, under the above heading, in your issue of June 24, it would be of interest if the author would give the standard he adopts, i.e., that with which the final appearance of relief, as seen in the stereoscope is compared in order to determine its accuracy.

From the context I assume that the author's standard is the relief shown by the actual object situated 12 inches in front of the eyes. If this is so will he please explain why a lens separation of 2½ inches (corresponding to the average interocular distance), with the object 12 inches from the lens yields a stereoscopic slide showing exaggerated relief? That it does so we know, and as can readily be seen by examination of the slide reproduced (Fig. 3). Why then do we get correct relief with a more or less distant object photographed with a lens separation equal to the interocular distance of 2½ inches? In both cases we photographed the object under the

same angle as that under which we view it, and yet when we view the results in the same stereoscope one shows correct, and the other incorrect, relief.

The author apparently assumes that the separation values he gives will yield slides showing correct relief with whatever form of stereoscope is used for viewing, but on consideration it will be obvious that the angle under which the stereo image (not the actual prints) is viewed will depend upon the focal length and separation of the stereoscope lenses. Of stereoscopes at present on the market this angle varies from 3 deg. to 12 deg. when using a slide having a print separation of 2½ inches, so that great variation in relief of the stereo image of any particular slide may result. Such a difference is readily seen on viewing either of the slides reproduced to illustrate Mr. Bedford's article, first in an American lenticular-prismatic stereoscope with lenses of 8-inch focal length, and, again, in a Baird's "Lothian" lenticular stereoscope of 5½-inch focal length.

It is absolutely essential for the production of correct relief that the object be photographed under *the same angle as that under which it is to be viewed in the stereoscope.* There are several methods of determining this, but unfortunately all of them are difficult for the average stereo worker to employ.

With reference to the three illustrations showing the cube, shell, and match: for accurate comparison all factors should be constant with the exception of the one under consideration (lens separation), but here a variation in print separation is noticable, amounting to 1-16 inch between Figs. 1 and 2. Since this factor also exercises an effect upon the stereo image it should and could have been avoided with very little trouble.—Yours faithfully, THOS. J. WARD.

Leytonstone, E.11.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. Y. L.—We regret that the subject is not one that we can deal with. If you are a member of the P.P.A. we would advise you to write to the secretary, as we believe there is some agreement on the question. If you are not a member we would advise you to become one. The secretary is Mr. Lang Sims, 437, Brixton Road, S.W.9.

H. L. E.—It is almost impossible to advise you on the question of lighting without knowing size of studio and the class of work you intend to do. 3,000 c.p. is about the minimum you could do with, and for this we should recommend three 1,000 c.p. lamps. If you write to the General Electric Company, Magnet House, Kingsway, London, W.C.2, and ask for their photographic list you will find out all about lamps and fittings.

W.B.—The following is a simple waterproofing solution for wood:—

Asphalt	4 ozs.
Pure rubber	30 ,,
Mineral naphtha	10 ,,

Apply with a stiff brush and give three successive coats, allowing to dry between each. The vapour from this solution is very inflammable. See also the process advocated by Mr. D. R. Gibbs, on page 328 of the current "Almanac."

C. L. S.—We should think one of the commercial finders composed of a concave lens with a sighting vane would be most convenient with the camera you mention. If you want to make one you must fix a rectangular wire frame, 6½ x 4¾ inches, with cross wires at right-angles on the front, and a sighting vane on a level with the intersection of the wires on the back frame of the camera at a minimum distance of 7½ inches. On placing the eye at the vane you will see the exact view included in the frame. This finder will be correct for any lens.

C. H. A.—You can easily replace your incandescent gas light by an ordinary metallic filament lamp, one of 32 c.p. is sufficient for bromide paper. For gaslight paper a small half-watt of, say, 200 c.p. would be better. We are afraid that you would hardly find it worth while to have your premises wired for electric light for this purpose only. There are several good incandescent mantle lamps which burn paraffin, or you might fix an acetylene light in place of the present burner. We do not think there would be any appreciable difference in cost with any of these systems, probably acetylene would cost the most. The gas shortage is not likely to continue very long now, so that we do not advise you to go to any great expense. Why not try a good ordinary duplex wick paraffin lamp? Many camp photographers printed by these during the war.

S. H. A.—The method of removing the letters from your shop-window will depend upon the nature of the cement used for fixing. "The Pharmaceutical Journal," dealing with the subject recently, said that if the cement is a water-soluble one, it is possible that the application of water containing some hygroscopic material, such as glycerin or calcium chloride, would be effective if applied with a pipette to the top part of each letter where it joins the glass. Allow some time for the moisture to take effect, and then apply a suitably folded pad of cloth, wrung out of hot-water, to the letter, avoiding the window glass as far as possible. This will cause some slight movement of the letters, and, at the same time, tend to soften the cement and promote action of the liquid used. Other solvents may, however, be necessary—hydrochloric or sulphuric acid, for example

W. D. O.—We think that you need to study some work on the art of projection before you start on the construction of an enlarger, as you do not seem to have a very clear idea of its requirements. Replying to your specific queries we can say: (1) The general idea is quite correct. (2) There is less spherical aberration in the double form. (3) The focal length of a condenser is usually half its diameter; with a large condenser it may be rather more. You can alter this by making the curves deeper or shallower. (4) It is useless to attempt to construct a practical condenser on the lines you indicate. In the first place, the curvature of a clock glass is not nearly accurate enough, and it is almost impossible to keep the cells liquid proof, with the great range of temperature to which it is subject. Water will answer as well as any other liquid. (5) The negative carrier should move. The axes of the objective lens and the condenser should be in the same straight line. (6) No. To enlarge from a whole-plate you require a lens capable of taking a whole-plate negative. You would require a lens of abont 10½ ins. focal length, with an aperture of at least *f*/8. (7) An inverted mantle would be sufficient for anything except great enlargement from dense negatives.

Contents.

SUMMARY.

The first of a series of chapters on photography for the newspapers, written by Mr. W. Lancelot Vining, until recently art editor of the "Sunday Pictorial," appears this week. It is, we think, the first occasion on which the subject has been dealt with by one regarding it entirely from the inside office standpoint. The first chapter sets forth the altered conditions which now favour the free-lance press photographer, and the second gives an insight into the working of the "art" department of an illustrated newspaper. (P. 395.)

In his presidential address before the Photographic Convention assembled at Bristol, Mr. C. H. Bothamley reviewed photographic progress of the past twenty or thirty years, particularly in reference to the work of Hurter and Driffield, and to the origination of the methods of physical chemistry. He urged that current communication of scientific research should be expressed in more comprehensible language. (P. 398.)

The fourth chapter on the H. and D. doctrine deals with the time of development required, with a given plate and developer, to produce a given degree of contrast relatively to the subject on one hand and to the printing paper on the other. The calculation of this necessary time of development follows a complicated mathematical law, but the application of the law is rendered a matter of ordinary arithmetic by means of tables worked out some years ago by Mees and Sheppard. (P. 401.)

In a leading article we draw some comparisons between ancient and modern lenses, and raise the question of the advisability of more ample bonding and substantial build of the lens mount for those who do not regard ultra portability as the chief consideration. (P. 394.)

An often neglected point in the making of enlargements is the use of a mask on the negative for the purpose of cutting out the illumination of the margins of the sensitive paper or of the white paper with which many enlarging easels are surfaced. (P. 394.)

Wear of the light-trap in plate holders is often an unsuspected cause of fog. Some hints on renewal of the material used in preventing entrance of light when the shutter of a plate holder is withdrawn are given in a paragraph on page 394.

For the maximum physical permanency of the emulsion film on the glass of negatives, experience is in favour of the recommendation to avoid the use of an acid or alum bath at any stage in the making of a negative. (P. 393.)

EX CATHEDRA.

Cabled Photographs of the Fight.

The "Daily Mirror" is certainly to be congratulated on the reproductions of the photographs of the Dempsey-Carpentier fight which were obtained by telegraphic transmission and appeared in its issue of Monday last. It is, we suppose, the most successful, as it is also the most notable application of the method in which the "Daily Mirror" has interested itself for some years past. Inasmuch, however, as a boxing contest is one of the most difficult of events to represent at all adequately in a few photographs, we cannot help thinking that the results of such a technical feat as this scarcely repay the labour and expense of getting them. The public no doubt sets great store by pictures, however imperfectly they may represent a prominent event, but there can hardly be two opinions that an impression of Carpentier's fight with his opponent is much more vividly conveyed by his own written account of it, which is also published by the "Daily Mirror." There are, of course, many other news events which lend themselves better to photographic representation, and one will watch with interest the progress made by the "Daily Mirror" in transmitting such photographic results by cable. Meanwhile, we feel some satisfaction in noting that the word "telephotograph" has been dropped as a description of these results, although without any substitute being offered. "Telectrophotograph" is, perhaps, not too cumbrous for regular use, and is sufficiently descriptive.

* * * *

Preservation of Negatives.

The time has perhaps gone by when it is necessary to caution the technical photographer as to the importance of thorough fixing and washing, and particularly the former, as a condition for the reasonable permanence of negatives. But it may be doubted if makers of negatives generally give sufficient consideration to other factors which greatly determine the physical permanence of the gelatine film which bears the silver image. It is quite true that in many cases this is not a matter of great importance, since defects of this kind make their appearance only after the lapse of a considerable number of years. Nevertheless, instances have come before us of very grievous experiences, for example, the rotting of the films of a whole series of valuable negatives. Although precise evidence of the cause of such deterioration as this is lacking, it is probably more than a coincidence that negatives which have suffered in this way were made in the days when it was customary, on account of frilling difficulties, to use an alum bath before fixing. Apparently, the employment of the modern fixing-hardening bath is less open to objection on this score, but at the same time we think it is a sound maxim that for the utmost permanence of the gelatine film of a negative the latter should have come in contact only with neutral or alkaline solutions from start to finish. Alum, apart from its tanning properties,

is a weakly acid substance, and the deleterious effects which it appears to produce in course of years may very likely be occasioned also by purely acid baths, for example, the weak solution of hydrochloric acid, which is recommended for removing the final traces of phenosafranine dye from plates which have been de-sensitised before or during development. The experience of years undoubtedly points to the advantage of following development by a fixing bath which is neutral or alkaline.

* * *

Developing Cut Films. A good many people who have been adopting cut films for portraiture and commercial work have found some difficulty in getting as perfect negatives as they have been accustomed to with glass plates, not with reference to the quality of the image, but to what may be termed mechanical defects. The principal trouble seems to be unevenness, caused by the fact that the film does not sink to the bottom of the dish as a plate does, but has a tendency to float, the slight curl causing the edges to be thin and streaky. Again, in fixing, if films are allowed to overlap there will usually be a line, especially if the developer is not well rinsed off. With care these defects may be avoided, but it is very much better to eliminate them, and also the risk of scratching during any of the manipulations by using the special clips and tanks made for the purpose. The film is inserted in the clip with the minimum of handling, and can remain in it until dry. The cost of the clips or frames is rather heavy where a large number of films is handled daily, and we think that a simple form would be welcomed by those who appreciate the undoubted advantages of film negatives.

* * *

Light-Traps. It is within the experience of most photographers that inattention to seemingly small details has resulted in defects in negatives difficult to trace, perhaps even resulting in total loss of valuable exposures. An instance came under our notice recently. A photographer after using a camera for some years began to be troubled with a band of fog across his negatives. At first the dark slides were suspected, but after careful tests it was found that these were not responsible for the trouble, which was at last traced to the fact that the strip of velvet glued to the back frame of the camera, for the purpose of a light-trap, had become worn, thus admitting stray light. After long use velvet loses much of its original "pile," and then is, of course, totally unfit for its purpose. Many camera makers now fit plush in place of the velvet originally used for their cameras and dark-slides, and in some cases the extra "spring" of plush has a better light-stopping power than that possessed by velvet, though there is a tendency for small particles of the material to become loose and find their way to the surface of the plate, where they become a cause of white spots that are exceedingly difficult to touch out on account of their peculiar shape. Especially when the slide is new this should be watched for; and it is a good plan to brush the finger rapidly over the plush prior to loading the slides or exposing plates so that any loose particles will be removed.

* * *

Masks in Enlarging. It is not generally appreciated that when a negative is not masked by the edge of the carrier of the enlarging lantern it is necessary to use some means of preventing any unnecessary light from reaching the easel upon which the bromide paper is fixed. It is quite a common thing to sandwich a small film negative, say $3\frac{1}{4} \times 2\frac{1}{4}$, between two half-plate or smaller glasses, and to allow a flood of light of much greater intensity than that passing through the negative to emerge from the lens. If the easel has a dead black or even a deep yellow surface, this does little harm; but if it falls upon what is often used, viz., a white card marked with the various paper-sizes, it is extremely detrimental to the resulting enlargement. A simple and convenient arrangement is a mask with an opening rather smaller than the film cut from stout black paper; that which is used for packing bromide paper answers perfectly. Along one edge of the opening is pasted a strip of the same paper, so as to make a narrow groove, into which an edge of the film is slipped. This keeps the film in place and prevents it moving while the second glass is placed over it. For small glass negatives a cardboard carrier, made upon the lines of a dark slide plate carrier with one clear glass, will be found perfectly effective.

THE BEHAVIOUR OF LENSES.

It has been announced, and, indeed, almost goes without saying, that the very complete photographic equipment of the Mount Everest Expedition underwent severe preliminary examination at the National Physical Laboratory at Teddington. That is as it should be, since in such cases, not only ought no risks to be taken, but it is necessary also to select by careful competition among various available types the best, at any rate for the purposes in view. In all ordinary circumstances the individual photographer who buys a new first-class lens may be satisfied that his instrument has undergone tests which, if not as comprehensive as those applied at the National Physical Laboratory, are eminently practical, and calculated to assure the performance of the objective under any reasonable conditions. But lenses are often acquired as to the behaviour of which no sort of certainty can be felt. Even if they bear the names of good makers they may have been subjected to rough usage, or their qualities may have been impaired by the mere effluxion of time. As a matter of fact, most of the lenses made forty odd years ago are "wearing" very well. The glass is hard, and the mounting solid and generally of excellent workmanship, as befits a product of the Victorian Age. Here and there re-balsaming and a touch of dead-black varnish may be needed, but there are thousands of old rapid rectilinears, rapid and "portable" symmetricals, and wide-angle lenses now doing just as good work—and very good work it is—as they did nearly half a century ago. With some of the later introductions it is impossible to feel the same confidence. The formulæ to which they have been constructed may be impeccable. But not infrequently some of the glasses used are soft or liable to change of colour, the mounting is flimsy, and the quality of endurance is sacrificed in order to procure extreme and often unnecessary portability.

It is a postulate that the potentialities of modern lenses are greatly in advance of those of the older instruments, but we are talking now, not of possible performance, but of actual behaviour, and our belief is that the actual behaviour of many fine up-to-date objectives after hard wear and tear, or in difficult circumstances, is not all that could be desired. Some of the deficiency, no doubt, is unavoidable. Where extreme rapidity and other special qualities are essential it may be necessary to use abnormal glasses, the surface of which is rather tender, and the permanence of which in regard to colour

cannot be guaranteed. But the all-round standard of mounting is not as high as it ought to be, and would be if more attention were paid to the behaviour of the lens in the hands of the average worker, and less to its size and appearance. It was a bad day for lens-making, for instance, when aluminium first came to be used for lens mounts. Some of the later alloys of aluminium, no doubt, are very satisfactory, and the gain in lightness is often most acceptable. But we shudder to think of the hundreds of good lenses which have been put into mounts utterly unfitted to stand even ordinary usage for more than a few years at most. As to aluminium screws, especially when their intercourse with brass flanges has been "frequent and free," the less said the better.

The average British manufacturing optician doubtless knows his own business extremely well, and it might not be entirely to his advantage if his lenses, and more particularly, perhaps, his photographic lenses, lasted indefinitely. But still less will it be to his ultimate advantage if, say, twenty years hence, it will be a not uncommon observation that So-and-So's old lenses can no longer be trusted, because their mounting has become defective, and can only be replaced at prohibitive expense. Lens-makers accordingly might consider the suggestion that, as an alternative to the mounts which they are constrained to supply to amateurs craving for extreme portability, and to makers of cameras in which the size of the lens is an important consideration, they should make a mounting of a more substantial and really workmanlike description. This in most cases might advantageously include a hood, which all the old lenses used to have, and which unquestionably often improves the behaviour of lenses, especially when working against the light. Of course, the extraneous light can be screened to some extent from a hoodless lens by holding a hat over it, but nowadays amateurs, at any rate, are not as a rule very thoroughly taught, and this simple precaution, very seldom omitted by practical workers, even when lenses were hooded, is often neglected with anything but pleasing results.

The behaviour of a lens may depend, not only upon the manner in which it is handled, but also upon the reasonableness or unreasonableness of the demands imposed upon it. The protean capacity of some lenses, as quite legitimately advertised for the edification of those who cannot afford more than one or two objectives, is responsible for some exaggerated hopes of the performance of these instruments when used otherwise than in their normal arrangement. With a very few notable exceptions the single components of double and triple combinations do not work really satisfactorily at full aperture, a point which may readily be determined by going over the image on the focussing screen with a focussing magnifier, and comparing the definition with that given by the complete lens. The same remark may be applied with increased emphasis to the behaviour of ordinary telephoto combinations, as distinct from highly-corrected single focus tele-lenses, such as the Telecentric, the Dallon, and the new Cooke. But the mistake is often made of expecting too much from complete double and triple combinations, especially where these have a very large full aperture. It is probably safe to say that only very occasionally does an *f*/4.5 lens stopped to *f*/11 cover a plate two sizes larger than that for which it is listed as satisfactorily as an *f*/6.3 lens of the same focal length may reasonably be expected to cover it at the same aperture. It is not quite fair to ask that it should, any more than it would be reasonable—assuming that one dared to ask a highly-trained chef or "upper housemaid" to do the work of a "general." Photographic lenses are mostly very excellent tools, doing what they profess to do with precision, and often doing a great deal more quite passably, or even admirably. But if, to borrow a term from another science, their potential is high, they must be, as Dickens's butcher in "Martin Chuzzlewit" said of meat, "humoured and not drove."

PHOTOGRAPHY FOR THE NEWSPAPERS.

[Below we commence the publication of a series of eight chapters on the supply of photographs to the newspapers written by Mr. W. Lancelot Viming, until recently art editor of the "Sunday Pictorial." So far as we know this is the first occasion on which the subject has been dealt with by a writer intimately acquainted with the production of an illustrated newspaper and considering the matter from the angle of the art editor. Mr. Viming, who has spent his life in press photography, first as a free-lance and subsequently as a press photographer on the "Daily Graphic" and "Daily Mirror," begins by emphasising the altered conditions which at the present time create more opportunities for the non-staff photographer of news subjects than has previously been the case. His articles will appear week by week until our issue of July 29.—Eds. "B.J."]

I.—INTRODUCTION.

The time has now been reached when the supply of photographs for illustrating both newspapers and magazines has fallen far below the ever-growing demand, a demand that is not a myth, but a very solid fact, and this demand is far more likely to increase rather than diminish in the future.

Up to the year 1914, the staff photographers of picture papers and photographic agencies covered the country, or, to be more correct, the world from London; but times have changed with the War, which is responsible for the enormous increase in travelling expenses, and also in the cost of every article used in the production of photographs and process blocks.

The result of all this is that where, previous to the War, a photographer was sent 200 miles to cover a news story or work up a "stunt," to-day that same event or a similar one will be allowed to pass without having a plate exposed on it, the only reason for this being that the expenses would have been greater than the value of the photographs obtained, and no newspaper or agency, unless they are philanthropic institutions, will stand for this.

The fact, however, remains that had one of these missed events been photographed by a local correspondent and the prints sent to the newspapers, they would certainly have been published. This is where the local photographer, whether professional or amateur, should come into his own, provided he can handle the situation in a workmanlike manner.

There will always be a certain number of big news events which will have to be covered from headquarters; but the

events which can be called "hardy annuals" or those which occur suddenly ought in future to provide a regular source of income for the correspondent photographer.

I am often asked the question:—"Are local photographic agents reliable?" Like the curate's egg, they are good in parts, and there is plenty of room for improvement in the majority of their work, which would earn for them far more money than they are at present making, and thus help meet the ever-increasing demand for good news photographs.

A great deal has been written from time to time in the photographic press on the subject of amateur photographers making their hobby pay its way, or at least meet some of the expenses, and the method recommended was to supply photographs of news and other subjects of interest to the illustrated papers and magazines.

In the days when photography was my hobby, and not a business, I diligently read all the articles on this subject, and carefully carried out the instructions and advice; but I must confess that I never succeeded in earning the amount of my plate bill, and that was when quarter-plates were 1s. per dozen.

Since that time I have earned my living with my camera, working for the "Daily Graphic" and the "Daily Mirror." With this experience, together with my present work as art editor of the "Sunday Pictorial,"* I think I can see why so many photographers fail to extract cheques from picture papers, and it is my hope that what I am going to tell them will at least help to put them on the right road for success.

The articles I read in the past were very helpful as far as they went, but that was just where they falied—they did not go far enough—and I am inclined to think that the majority of the writers had not been through "the mill." of Fleet Street with a camera, nor had filled positions as art editors of illustrated papers, and that is why their advice stopped short of the details, which mean the difference between failure and success.

Many of my readers have, I expect, often submitted their work to the art editor of their favourite picture paper. They have perhaps done this over and over again, and yet not had a single publication. They then give up in disgust, and blame the art editor, but never themselves, whilst if only they knew the truth the fault was theirs seven times out of ten.

I have hundreds of prints sent in every week, and I feel like shedding tears morning after morning when I see what the post brings and the good material wasted by having been badly handled; pictures that over and over again I was in need of, and would have published.

The figure in £ s. d. lost by correspondents in one week is surprising, and in the majority of cases poor composition is to blame.

Picture papers must be bright, and, as you all know, bright photographs are well thought out and composed, not just "any old snap."

I have noticed very often that where a commission has been given to an agent he has not been too careful in executing it, whilst the agent sending in on chance seems to take far more care with his work. Always put your very best work into every process of making a photograph when you intend sending it to a newspaper. If you are working on an undated event, and your first attempt is not your best work, do it again and secure an improvement. It will pay you in the end.

Here is an illustration of what happened quite recently. A photographer called upon me to submit a series of prints of a well-known footballer at home, to be used in the series running weekly in the "Sunday Pictorial." The photographs were very bad, and seemed to me to contain all possible faults, and would have been a disgrace to a very medium photographer. I declined them with thanks, and was then informed that as the photographer had sole rights of this football player, he would be pleased to do him again, and show me some better work.

An art editor wants to see the best work the first time. I have no sympathy for a photographer working on these lines, but I am sorry for the person who has given exclusive rights of his photographs to such a slack worker.

I want to make it quite clear, before I proceed any further, that I am not out to teach anyone photography, and I shall only touch very briefly on the technical side when necessary; but what I am hoping to provide is information (which I think will prove valuable), the result of personal experience during the past ten years in Fleet Street, and obtained during my journey from press photographer to art editor.

I am going to take it for granted that my readers can correctly expose a plate or film, and obtain a clear and clean print, either enlarged or contact, from their negatives. If they cannot do this ten times out of twelve they had better set to work and unearth the cause of their failures, and set matters right before they commence sending undeveloped plates or films to newspapers. Nothing does a correspondent so much harm as to wire an art editor that good pictures are on the way to the office, and then when the plates are developed they turn out to be "duds," because in all probability space will have been kept, and another story will have to be found, and this may not be an easy matter if it is near the hour of going to "press." One result is certain—the sender will be noted as unreliable, and commissions will not go his way.

The motto of every photographer working with a view to publication should be "Give them something new." I will illustrate exactly what I mean by this when I tell you how I came to turn up civil engineering for the very uncertain life of Fleet Street. As an amateur photographer I can say without fear of contradiction that I was a very keen one. I did not put my camera away during the short and dark days of winter. I used these days to test fast plates and experiment on under-exposure. Lens testing was also a favourite of mine, but with present prices I cannot recommend this as a hobby. But, looking back at those days, I think the experience gained was worth the price paid in hard cash. Sports of every description were my favourite subjects, and during the football season I turned my attention to League matches. There were not a great many papers publishing photographs in those days, and I realised that I must get something new and different from the staff photographers of the "Mirror," "Sketch" and "Graphic." This must also be the aim of every photographer taking on press work. Take any old subject, and treat it in a new way.

At a football match I found that all the photographers took up positions near the goals, and week after week produced the same type of result. This made me decide to work from the side touch line, using a long-focus lens when possible, and getting an entirely new view of "attacks on the goal." Sunday morning found me early in Fleet Street with enlarged prints, and on Mondays I usually found that I had two or three publications, and I always put this down to the fact that I was sending in a new type of picture. I had not been doing this for many weeks when I received an invitation to join the staff of London's largest photographic agency, because I had been beating their own photographers at football matches. I accepted, after much anxious thought, as I was warned on all sides of the dangers of the "Street of Ink," and I realise now that these warnings were not given without a good reason, and I want my readers to think, not twice, but many times, if there are any of them thinking of giving up work they may be doing now to take up press work as a profession. The life may sound easy and pleasant, but really it is very hard and very exacting. You may make a mistake in your present work, and nothing very serious will happen. In press work, every mistake, however small, is serious.

My endeavour will be to make these chapters a guide to the photographer who may from time to time have photographs which may be valuable for illustrating papers and magazines, but who at present is quite ignorant as to how to turn his work to good account.

How many photographers who happen to have negatives of some really big news event know how to deal with them, and realise their full value? From what I have seen as an art editor, I can say that very few do.

* These articles were written before Mr. Vining had resigned his position some two months ago.—Eds., "B.J."

II.—THE ART ROOM.

Have you ever visited a picture paper office and seen the working of the art room where all photographs are dealt with? I expect the answer is in the negative, so we will pay a visit to one, and you will then know exactly what happens in the day. The art room is under the charge of the picture editor, who alone will decide whether a photograph is published or returned to the sender with a polite "regret form." This individual must be studied through the paper he produces, as all art editors have their likes and dislikes, and it is very important that contributors should find them out by carefully watching his paper day by day or week by week. To the art room is attached the photographic section, which comes directly under the control of the art editor. Each evening the diary of events for the following day is fixed up, and where these are at a distance, the decision is made as to whether to send a staff photographer or instruct a local man. If the former, the photographer will pack his bag and start away. He may say that he has an engagement, and "she" will be waiting and he cannot let "her" know, but it is all to no purpose—"she" just waits. A photographer is the most uncertain person to make an engagement with, because his time is never his own. He is rather like a fireman. I remember an occasion when I arrived at the office one morning, and within an hour had left on the boat-train for the south of Spain. I was away three weeks, and returned late on a Thursday night. When I reached the office on the Friday morning I was sent off to Monte Carlo for nearly a month. Both these jobs were very enjoyable ones, and there were no complaints from me, although I believe my wife had a few "words" with the art editor over the 'phone. Having fixed up his own staff, the art editor will select the events to be covered by local correspondents, and instructions will be sent to them by telegraph or telephone. A card index is kept in the art room giving the towns (large and small) and the names and addresses of the local photographers. Some of these will no doubt have been appointed local correspondents, whilst others have earned their places on the cards by their work in the past.

Papers and agencies make a careful note of the class of work sent in, and a record is kept for future reference. Once it has been proved that Jones, of Blanktown, can be trusted to turn out good work, commissions will often be sent to him, and news events in his district will not be covered by staff men. A note may also be made that Smith is very good at social events—weddings, hunt meets, and even funerals, but Wilson is the man for sports, or anything requiring high-speed work.

The following morning the remaining photographers will be given events to cover according to the news which has come in during the night, and very often one or two more local correspondents will be instructed to cover certain news in their district. The post has by this time arrived and been opened, and the art editor will make his selection, very often using horrible language over the "might-have-beens" had a little more care been expended over their production. By the time the post has been dealt with, the "office conference" will be ready to "sit," and here the policy of to-morrow's paper is decided upon, and yesterday's work is criticised. The photographic agencies will now be calling with their photographs, and the first edition for Ireland and Scotland will soon be taking shape.

We will suppose that during the morning news arrives over the tape machine that a serious railway accident has taken place near Blanktown, and that the Mayor and one or more prominent men of the town have been killed or injured. This is what will follow. The card index is first of all consulted, and under Blanktown we find, Jones, A., 40, High Street (reliable), 'phone 62. Will take message. A trunk call is put through, and the following telegram is also sent:—

"Cover railway accident. Rush pictures for early edition. Collect portraits. Wire time of arrival."

If the story looks like being a big one, a staff photographer will be sent to help the local man. Later in the day a wire will be received from Jones something after this style:—

"Undeveloped plates arrive King's Cross 6.20. Hope to send portraits later. Please return slides at once."

All day long photographic salesmen are calling with prints, and staff men are returning from their engagements, and once the first edition is finished preparations are made for the next. About five o'clock the night art editor arrives, and the evening conference is held, after which he will take over the picture pages. He will know by the list of events what is coming in, and the time they are expected to arrive. His work will go on until the last edition has been "put to bed," and this will be somewhere round about the early hours of the morning. It is almost certain that some of the agencies will also have prints of the Blanktown smash, sent to them by their local agents, and they will have warned the art editor of the time that they expect to submit them. But Jones' ordered photographs will be used, unless he is badly beaten by a local rival, either on the score of photography or time of arrival. But even if Jones does fail he will receive a cheque to cover his time and expenses, because he was given a definite order, but a note would be made of his failure in this instance.

The work in the art room is always carried out against the clock, and more often than not at a very high speed. Pictures are changed from time to time to suit the edition, or to keep pace with the latest news. For instance, the edition of the "Sunday Pictorial" which appears in Ireland is entirely different from the one published in London.

Every care is taken of plates and prints received from correspondents, but these people must get it out of their heads that their photographs are the only ones arriving at the office, and that therefore it would be quite out of the question for them to get mixed up with any others, so that there is no need to put any name or address on them. I am sure this is what many of them must think, because every day this is what happens, and it causes endless annoyance and trouble to the art room staff, as well as to the sender, who will never under any consideration see or believe that the fault is his or hers. If you are sending prints, put your name and address on each one, and write as clearly as possible. When sending developed plates or films write it along the edge, and when these are undeveloped see that your name and address is clearly written on the box, as well as being inside with the titles. Unless you do this, the fault is the sender's if they are lost.

W. LANCELOT VISING.

(To be continued.)

CAMERAS AND CHARACTER.—In an article appearing under this heading in the "Oldham Chronicle," the writer says: Mankind is a mine inexhaustible, and the exploration of that mine always yields some profit to the photographer, be he seeker after beauty, or student of men and women. A photograph is much more to the man taken than to the taker. Accordingly, a wise man destroys many plates, for a broken plate may save a broken friendship. Photography is an absorbing pursuit, but if it costs you a friend you have paid too dear for your whistle. With the bold lovers of truth, those who like Cromwell want the wart on the nose, there is no difficulty. They know that little mannerism is a bad one; they know that trait which the camera reveals is in the character, and don't mind acknowledging it. The average man and woman want a "nice" picture, and put niceness ahead of truth. It is a bit of that self-deception with which most of us go through life, a light cloak that a gust of truth blows aside, but which does well enough in fair weather. Thus in photography, as in other pursuits, the moment we touch human beings we enter into the realm of moralities. No photographer can ignore it. And as a building arises out of many bricks, so out of his numberless observations a fine structure of solid knowledge is erected. If the proper study of man is mankind, no one can surpass the photographer in opportunities for such study. A sitter sometimes shows more of himself in five minutes than in five hours. In those minutes a short study may be made which reveals the essential, the often unseen bases of character. The face may be all that goes to the plate, but the sitter's mind often goes into that mental portrait gallery which the man with the camera is forming, for though he began with the sole notion of becoming a photographer he ends by becoming one who knows—in short a philosopher.

THE PHOTOGRAPHIC CONVENTION.

UNDER continued conditions of fine weather, the Photographic Convention of the United Kingdom met at Bristol on Monday last, July 4, to hold its 33rd annual meeting. The proceedings opened in the great hall of the Merchant Venturers' College, which is the headquarters of the Convention, with a meeting at which a welcome was extended to the members by the Lord Mayor of Bristol. The new president, Mr. C. H. Bothamley, M.Sc., F.I.C., was then installed in his chair of office, and delivered his address, the text of which appears below. At the annual general meeting which followed, suggestions for the place of meeting of next year's Convention were considered. It was resolved that, if practicable, next year's Convention shall be held at Shrewsbury. York was named as an alternative place.

In the evening a reception was held at the Bristol Art Gallery, at which members were received by Alderman Dr. C. H. Cook and Mrs. Cook, on behalf of the Lord Mayor.

On Tuesday Conventioners visited Gloucester under the guidance of Mr. Sydney A. Pitcher. By courtesy of the Dean of Gloucester, Dr. Henry Gee, permission to photograph in the Cathedral was granted, and members had the privilege of being personally conducted over the Cathedral. In the afternoon parties were formed for viewing the antiquities of the city and the Norman Chapel of St. Mary Magdalene under the guidance of Mr. George Embrey, F.I.C., F.S.C. On return to Bristol a lecture was delivered at headquarters by Mr. C. F. W. Dening, F.R.I.B.A., on "The Old Houses of Bristol."

Wednesday was spent in Bristol, when special facilities were afforded to Conventioners for photography in the cathedral and the great church of St. Mary, Redcliffe, and for visits to the chocolate factory of Messrs. Fry and the tobacco factories of Messrs. Wills. In the afternoon Mr. Roderick J. Fry and Mrs. Fry entertained the members at their home at Abbots Leigh, when the official group of the Convention was taken by Mr. F. Bromhead, of Clifton. The annual dinner was held in the evening, when a crowded company assembled under the chairmanship of the president.

Yesterday, Thursday, the Conventioners were to visit Chepstow and Tintern under the leadership of Mr. Bothamley, and to-day are making excursions to Bath and Lacock Abbey with Mr. Herbert Lambert, of Bath, as their guide. At Lacock, by permission of Miss Talbot, grand-daughter of Fox Talbot, photography will be permitted throughout the picturesque Abbey, which was Fox Talbot's home and where he carried out his classical experiments in the origination of photographic processes. A collection of Fox Talbot relics had been arranged by Mr. Lambert for the inspection of visitors, who would have the opportunity of examining the various models of cameras employed by Fox Talbot for the making of negatives on paper and also his appliances for the working of the Daguerreotype process. To-night the formal proceedings of the Convention will be brought to an end by a lecture by Mr. C. P. Crowther on "The Making of Portraits."

At the headquarters of the Convention an exhibition of photographs is being held during the week, and includes a collection by the Professional Photographers' Association and a large number of prints representative of amateur work and including some notable colour Bromoils by Mr. Hazell, president of the Bristol Photographic Club. A considerable exhibition by members of the photographic trade is also a feature of the week.

THE PRESIDENTIAL ADDRESS.

My first duty is to express to the members of the Council my thanks for the honour they have done me in electing me as President of the Convention for the second time. It gave me great pleasure to accept the honour, although I am not unmindful of the responsibility that attaches to the office at the present time when we are trying to revivify the Convention and make good, and more than good, the set back which, in common with many other societies, we have experienced as a result of the war. I can only say that it will be my earnest endeavour to discharge the duties of the office to the best of my ability, and I am confident that I can rely on the sympathetic co-operation of the Council, the members in general, and our honorary secretary. We are still the only photographic society which at the same time includes in its membership all classes of photographers and those interested in photography, and, by meeting in a different place each year endeavours to stimulate interest in and promote the advancement of the art and its applications. We are all, I hope, convinced that the Convention has a distinct and specific place amongst photographic societies, and if rightly administered may discharge very useful functions.

It is now thirty-one years since I first had the honour of holding this office, and I find the temptation irresistible to take an outline survey of some of the more important advances that have been made in that period. Such a survey, even though concise, must be very incomplete, because photography, like other branches of applied science and art, has made enormous advances in both knowledge and practice. The literature has become too voluminous, and the field too extensive for any one man to attempt to survey it all, even if there were the necessary time.

The year 1890 was remarkable in the history of photography from both the practical and scientific points of view. During the Chester Convention, on the evening of Tuesday, June 26, Mr. Friese Greene, who was then and for some years afterwards a member of the Convention, gave the first public description of the first really practicable camera and lantern for taking and projecting on a screen photographic representations of objects in motion. The apparatus previously employed by Muybridge and by Marey was complicated, difficult to use and limited in its capabilities and range. Muybridge's method of lantern projection by attaching the consecutive pictures of a moving object to a large disc which rotated in front of the lantern condenser gave very striking and interesting results, but it is obvious that such a method must suffer from severe limitations. We should not forget, however, that some interesting problems of animal motion were solved by both Muybridge and Marey.

The real solution of the problem of moving pictures, however, was to take the successive negatives on a continuous transparent band and to project the positive images by means of a similar band moving across the optical system of a lantern. It sounds very simple, but its realisation in practice presented many difficulties. The late Mr. Friese Greene, however, was an inventive genius, and he led the way in that wonderful development which has introduced a new and dominant element in the recreation of human beings in all parts of the world. The kinema, cinema, or "movies," which you will, has come to be regarded as an essential factor in social life, and with the aid of the still more recent motor-car it now finds its way into the remotest country districts. Whatever criticisms we may be inclined to make, we are obliged to admit that it has brought recreation and enlightenment, pleasure, and instruction into the lives of hundreds of thousands whose share of such things has never been excessive. Apart from its recreative side, it is now common knowledge that the cinematograph may render greater service in education, in scientific research, and as a recording agent. I need only remind you of such important matters as the Arctic and Antarctic expeditions, and the investigation of motion in

industrial manual processes with a view to eliminate unnecessary fatigue and increase efficiency.

The pathos of it is that here, as so often, the pioneer secured but little of the great pecuniary reward that has accrued to others from his labours. The inventive genius in his case was not allied to that commercial training and instinct which is essential to the exploitation of an invention. It is possible that he was far from realising how much would come out of his invention; even the title of the Convention paper, "A Magazine Camera and Lantern," conveys but little of the real importance of the topic. It is some satisfaction to know that in the end the great industry that has grown out of this beginning did to a certain extent recognise how much it owed to Mr. Friese Greene.

About the same time there was published a scientific paper which marks a distinct epoch in the history of photography. I refer, of course, to the famous paper on "Photo-chemical Investigations and a new Method of Determining the Sensitiveness of Photographic Plates," by Ferdinand J. Hurter and Vero C. Driffield. Later there were other papers by the same authors, but whilst of great value they had not the same distinction of novelty. The great merit of the first paper is that it laid down very clearly the principles and practice of the methods to be adopted in investigating, not only the sensitiveness, but all the other main characteristics of the photographic plate and incidentally, of the various developers, intensifiers, and reducers with which a plate may be treated. It is remarkable that although their methods have been improved in detail and accuracy, their general plan of work is still followed, and the ordinary man who wishes to make similar observations for his own information can still find nothing more suitable to his purpose than an apparatus similar to that which Hurter and Driffield devised.

I need not emphasise the point that nothing helps the advancement of human knowledge in a particular direction so much as the invention or discovery of a powerful new instrument of research like the microscope, spectroscope, or the X-rays, or the working out of the lines on which a whole series of investigations can be best conducted.

The names of Hurter and Driffield are familiar to many photographers, but it is safe to say that a knowledge of their methods and results is confined to comparatively few. For this there are several reasons: a large part of their work had much less significance for the general body of photographers than it had for makers of photographic materials or for those who use photography for strictly scientific purposes. At the same time, their results had a very important bearing on photographic practice more especially as regards development of the photographic image. Secondly, they employed certain terms in a sense different from that in which they were generally used by photographers; for instance, they used, quite rightly, one of their fundamental terms "density," with its recognised scientific meaning of the quantity of a substance contained in a particular volume or area. Photographers, unfortunately, had acquired the habit of using this same word "density" to mean the opacity or light-stopping power of different parts of the negative. This point alone led to much misunderstanding, not confined to one side of the controversy. Thirdly, their results were presented in a mathematical form, and their powers of popular exposition were not always as brilliant as their powers of investigation and mathematical analysis. It is to be regretted that for so long a time no one has attempted to make Hurter and Driffield's work and its practical significance intelligible to non-mathematical photographers, but it is a matter for congratulation that this attempt is now being made in the "British Journal" by so capable an exponent as Mr. G. E. Brown.

Perhaps the great point in Hurter and Driffield's results is that they clearly defined for the first time the terms "under exposure," "correct exposure," and "over exposure," and showed how to obtain the characteristic curve of a plate, which represents the latitude of exposure and the range through which the particular plate is capable of giving correct representation, the minimum exposure necessary to give correct representation and the factor (gamma) giving the time of development necessary for obtaining a given degree of contrast. They also showed that the densities of the silver deposit in the negative corresponding with the differences between the brightness of various parts of the object have a constant ratio, which is determined by the exposure, and, within the range of correct exposure is not altered by variations in the composition of the developer. For the reason stated above, this became the storm-centre of the subsequent controversies. Hurter and Driffield failed, until a much later paper, to emphasise sufficiently the fact that whilst the ratio of the *densities* remains constant, the ratio of the *opacities* varies greatly with the time of development. Subsequently, with more extended investigations, they modified some of their conclusions and recognised that with a sufficiently wide range of developers as regards both nature of the reducer and the composition of the solution, there may be differences between the ratios of the densities corresponding with the same exposures. One of their principal practical results, that photographers could not, as they had believed, alter the relative densities of different parts of the negative by altering the composition of the developer in the course of development was much challenged (old beliefs die hard!) but has not been upset. The effect of adding a soluble bromide to the developer was another point on which new conclusions were arrived at and old beliefs disturbed. From their work and that of later investigators, it can be said that the main effects of adding a soluble bromide to the developer before development begins are (1) to reduce fogging of the unexposed parts; (2) to retard development, and apparently to make the plate less sensitive; (3) to reduce the size of the silver grains; with prolonged development however these effects disappear.

The Hurter and Driffield paper and subsequent controversies stimulated interest in the questions dealt with and led to much further research, notably by the late Sir W. de W. Abney and by Mr. Chapman Jones in this country, and by Eder and Scheiner abroad. One outcome of the general activity was the time method of development invented by Mr. Alfred Watkins, a former President of this Convention. Even more important was the fact that a continually increasing number of scientifically trained workers turned their attention to the investigation of photographic phenomena and processes.

Some ten years after the appearance of the first Hurter and Driffield paper, their work was repeated with improved methods, and materially extended by Sheppard and Mees, but the main conclusions held good. At the present time quite a number of trained and competent investigators, whose names will readily occur to you, are at work, and are obtaining valuable results. I shall not, I hope, be supposed to under-value what they are doing if I venture to express some regret that more pains are not taken to make the results and their significance more intelligible to those who would profit by the work if only they understood it. I cannot help thinking that there is sometimes an unnecessary display of those wonderful combinations of the letters of the Greek alphabet which bring delight to the souls of real mathematicians and dismay to the souls of ordinary people. If scientific workers are to receive the general recognition that they claim and deserve, scientific results must be made plainer to those who can use them and to the general public. A prominent public man lately said that the only people with anything worth saying at the present time were the scientific people, but that they were also the only people who did not know how to say it. Casting my mind back to thirty and even forty years ago, I share the feeling that at the present time there is much room for the cultivation of the art of popular scientific exposition. In 1890 the number of scientifically trained men devoting themselves to research work in photography was probably not more than a score. To-day we have in all civilised countries a large number of energetic and competent men engaged in the same field. The establishment of well equipped laboratories under able control in connection with important photographic undertakings and the organisa-

tion of the British Photographic Research Association are all full of promise for more rapid progress in the future. It would be a misfortune if the results obtained were unintelligible or unappreciated outside the ranks of specialists.

Whilst the behaviour of plates has been under investigation attention has naturally been paid to the problem of the nature of the latent photographic image; but although new theories have been advanced this fundamental problem still waits for a conclusive solution. It is the "elusive Pimpernel" of photography—always with us but always escaping capture.

In many, indeed, one might say all, of the most important processes of photography we are dependent on that large class of substances known as *colloids*, that is, substances which are of the nature of gum or glue, and as far as we know are incapable of forming crystals and incapable when in solution of passing through certain membranes, whilst under suitable conditions they form jellies or coagulate. Familiar examples in addition to glue and gum are white of egg, starch, and that evil-smelling substance which is sold under a variety of names in a variety of tubes and has the property of sticking much closer than a brother, especially where it is not wanted to stick.

Gelatine, which is only the purest form of glue, is, as you well know, used as a supporting medium in all our most familiar negative and positive processes. Our sensitive material is an emulsion of a silver salt in gelatine, and it has been recognised for some time that to completely understand the processes we must know what the gelatine does as well as what the silver salt does. Now those who have worked with it know that gelatine is always a weird and otentimes a wicked substance (human bodies contain a considerable quantity of gelatine—but I am not suggesting that as an explanation of anything).

In these later years there has developed a new branch of scientific work which studies the properties of colloids and the colloidal state. Often it is called *colloid chemistry*, but this is unfortunate, because the methods of research and the phenomena are physical rather than chemical in the ordinary sense of the word. It is sixty years ago since the peculiarities of colloids were recognised by the English chemist, Thomas Graham, but the development of our real knowledge of them belongs to this recent period of thirty years with which I am dealing. It could not happen before because the methods of investigation had not been devised. The science of colloids is, in fact, an offshoot of the development of physical chemistry.

This new branch of science, having to deal with newly-discovered phenomena, has had to invent a new set of terms and talks of such things as sols and hydrosols, gels and hydrogels, emulsoids and suspensoids, adsorption, dispersion, heterogeneity and cataphoresis. Though the language may be repellent, the country investigated is of great interest and importance. It is part of the broad border-land between chemistry and physics, and apart from its special and comparatively minor interest to us as photographers its study is of the greatest importance in connection with animal and vegetable life.

In photography we are concerned not only with the true colloids which have not yet been known to crystallise like gelatine or starch, but also with the colloidal state of substances that can crystallise, but which under certain conditions can exist in a state similar to that of the true colloids. Amongst such substances are gold, silver, and the insoluble halide salts of silver. The colloidal state implies a very minute degree of subdivision of the particles of the substance, not so minute as in the case of a true solution, such as salt or sugar in water, but much more minute than the finest powder that we can prepare in the solid state. This minute degree of subdivision connotes a very large area of surface for a given mass of the substance, and since physical and chemical interactions take effect at the surfaces of the particles of the interacting bodies it is not surprising that when in the colloidal state certain substances have the power of entering into a kind of quasi-combination, not as intimate as true chemical combination, but very difficult to break down when once it has occurred. This quasi-combination is usually called adsorption, and we have instances of it in the difficulty of washing certain lead salts out of paper, or hypo out of P.O.P. prints.

It seems quite clear that silver bromide can exist in a colloidal state in an emulsion if only in small quantity, and further research may demonstrate the importance of this state in the production of practically grainless photographic images. It has also been suggested that the latent image may consist of colloidal silver adsorbed by the unaltered silver bromide.

Passing from latent images and development to the developers it is noteworthy that early in the nineties Andresen and Lumière independently established the general relation between the chemical constitution of certain compounds and their power of developing the photographic image. Speaking generally, this power is dependent on the presence of at least two hydroxyl (OH) groups or two amido (NH_2) groups, or at least one hydroxyl and one amido-group in the same benzene nucleus, with the further condition that they are in the ortho-position or the para-position in the molecule. Some work was also done on the effect on the developing power resulting from other substitutions in the molecule. To this work we owe such useful additions to our list of developers as amidol, diamidophenol metol and adurol. Probably further research in the same field would be still more fruitful.

In its early days the Convention did much to make known to photographers in general the principles and practice of orthochromatic photography. Since 1890 the advance has been mainly in two directions, (*a*) the perfection of factory methods for utilising the sensitising power of the dyes of the eosin group for yellow and yellow-green, and (*b*) the discovery of new dyes of the cyanine group with sensitising power for orange and red rays. Out of these have come panchromatic plates with all their advantages in the rendering of coloured objects. The reluctance of so-called practical people to take advantage of improvements is illustrated by the fact that a photographer in a large town in the West of England told me a short time ago that he was the only photographer in the place who used panchromatic plates even for difficult colour subjects.

It must be a source of gratification to us all that owing to the researches of Sir William Pope and his colleagues at Cambridge during the war, cyanine dyes have been produced which are far superior as orange and red sensitisers to any of the similar products for which we were formerly dependent on Germany. Why certain dyes, and certain dyes only, act as effective sensitisers is still one of the unsolved problems.

I feel, however, that to the great mass of photographers the really important thing that has taken place in the past thirty years is the marked improvement in, one may almost say the perfection of, the manufacture of photographic materials. I doubt whether there are any manufactured products of such a delicate character, turned out on a large scale, so free from chemical and mechanical defects and so uniform in character as the photographic plates, films and papers produced by the leading photographic manufacturers. As a consequence, the elementary practice of photography has become remarkably simple and certain. From one point of view, this is a great gain, but I think that for many there has been a loss of that interest which arises out of difficulties and uncertainties. In the old days surprising things might happen at any stage of the processes—not as an occasional treat, but as a regular thing—and the endeavour to discover the causes of these occurrences and the methods of preventing them constituted for the more enthusiastic amateurs one of the chief interests of their hobby. The defects met with were sometimes the faults of the makers, sometimes the fault of the users. Nowadays photographic manufacturers have, of course, no such sins—but even in the old days they never confessed to any.

The ease and simplicity of modern photography is not without its drawbacks to photographic societies. The centre of interest has shifted from the processes of photography to the

applications of photography. Many of the opportunities for discussion and exchange of experiences that used to arise out of the less perfected processes have disappeared, and I think the difficulty of keeping up interest and enthusiasm has undoubtedly become greater. After all, so much research is being done that new discoveries of importance must be made from time to time and influence even the most routine practice. Moreover, the applications of photography are so numerous, the art has become so intimately a part of our daily lives, that with reasonable organisation and systematisation with certain definite ends in view, there should not be many failures to keep societies in active existence.

It is, it seems to me, the principal function of this Convention to stimulate general interest in photography especially in the place of meeting, to make known in an accurate but popular manner the results of original researches, and to encourage through research and critical discussion that continued progress and development which is the only safeguard against stagnation and decay.

C. H. Bothamley, M.Sc., F.I.C., F.R.P.S.

THE H. AND D. DOCTRINE.

In the preceding chapter it was explained that the action of development upon a plate is to increase the densities proportionately.

At a given stage of development of a correctly exposed plate the densities thus reach a value at which the opacities corresponding with them are proportional to the corresponding light-intensities from the subject.

The contrast of a negative relatively to the subject can be expressed by the ratio of the ratio of two opacities to the ratio of the corresponding light-intensities $\left(\frac{O_2}{O_1} : \frac{E_2}{E_1}\right)$.

The resulting ratio measures the contrast of the negative relatively to the subject. But contrast is more conveniently expressed in terms of densities and corresponding log exposures when it is the so-called gamma.

A negative of gamma less than 1.0 is of less contrast than the subject; and one of gamma greater than 1 of greater contrast.

The gamma of the negative is measured by a simple graphic construction when plotting the characteristic curve of the plate for determination of speed.

Plates differ as regards the maximum gamma which they will yield; and this maximum gamma, γ_∞, or gamma infinity is a measure of the contrast quality of a plate.

Different printing papers require gammas in some cases less—in others greater—than the theoretically correct gamma of 1.0.

The calculation of the time of development required to produce a given value of gamma is therefore of importance. It is complicated in theory but simple in practice, and is considered in the present chapter.

The series concludes with some notes on the principle of the Hurter and Driffield measurement of the speed of plates.

IV.—TIME OF DEVELOPMENT, AND CONTRAST.

Thus there is a maximum gamma, which varies with different plates, but with a given plate cannot be exceeded. But any gamma less than the maximum is determined by the time during which a given developing solution is allowed to act. The final and important point in the making of a negative which shall have the gamma required for the best (most correct) results on a given printing paper is therefore the calculation of the time of development necessary to produce a given gamma. This is the most complicated part of the process which we have been considering in these chapters. A graphic method of calculating the time of development was merely indicated by Hurter and Driffield in their last paper, published after Dr. Hurter's death in 1898. A means of making this calculation was first worked out by Mees and Sheppard, and was published by them in three papers ("Phot. Journ.," 1903, pp. 48 and 199, and 1904, p. 297), which are almost wholly mathematics of a kind which it is not possible to translate into popular language. They are among the least comprehensible of the early papers by Mees and Sheppard; which is saying a good deal.

Without considering the physical conditions which prevail in the development of a negative due to the "structure" of the gelatine and the diffusion of the developing solution into it and out again, it will be sufficient to remind ourselves that development is a process which gets slower and slower as it proceeds. We know from practice that with any ordinary developer the contrast of a negative increases from nothing very quickly during the first moments of development, and although there is an ample quantity of developer, grows more slowly during the later stages of development. We also know that some plates increase in contrast, with the same developer, more rapidly than others. It is therefore plain:—

(1) That the rule or law governing the rate of development must be a rather complicated one, and

(2) That there must be some characteristic property which causes one make of plate to develop more rapidly than another.

An Illustration of Rate of Development.

An analogy will perhaps help to explain these two elements in development. Suppose we have a heap of bricks, and we set a man to lay them all end to end in a straight line over a mile length, taking one brick at a time from the heap. Suppose also that our man, as a convinced trade unionist, is able to work at an even rate. At first he will lay out, say, 6 ft. of the line of bricks in very little time, but as the length of the line increases he will spend more and more time in fetching each brick, and when the line is, say, half a mile long it will take him a very long time to add 6 ft. to its length. The analogy is not a perfect one, but it illustrates a characteristic of development, viz., that at any instant the more of it has been done the slower the rate at which the remainder is done. It also illustrates that though the speed of the process becomes less at an increasing rate, there is a constant factor, viz., the rate of work of our brick layer; and if he could be induced to carry out the job at twice that rate, the mile of bricks would be laid in half the time.

The Velocity Constant of a Plate.

In this analogy the mile line of bricks represents the utmost contrast of the plate (i.e., gamma γ_∞), and the rate at which the workman sets out the bricks represents a property of the plate (for a given developer), which Mees and Sheppard called the "velocity constant," and which is commonly denoted by k. As shown by them, the rate of development (increase of gamma) is constantly decreasing: at any instant it is the difference between the maximum gamma obtainable and the gamma produced at that instant multiplied by the velocity constant, k; or expressing this in symbols:—

after t seconds, rate of development $=(\gamma_\infty - \gamma_t)k$.

While the rate of development is changing at every instant, because the difference between the gamma obtained and the gamma obtainable is changing, the other factor k is a constant. With the same developing solution and temperature, a plate of a certain value of k develops to a given

gamma in half the time required by a plate having half that value of k (for the same developer), providing both plates have the same γ_∞. This constant k ranges with various plates from about .03 to .3 (for the ferrous oxalate developer), and is very easily affected by variations in manufacture, such as the rate at which the emulsion on the plates is dried.

The Law of Time of Development.

Evidently, then, there is a definite law for the time in which a certain value of gamma is reached for a plate of given values of gamma $_\infty$ and k. Unfortunately, in mathematical symbols it is a forbiddingly complicated formula, and I know of no method of making it simpler. I would not introduce it into these notes were it not for the fact that in order to use it there is no necessity to understand it from the mathematical standpoint. By means of the table B. worked out by Mees and Sheppard the use of the formula becomes a matter of ordinary arithmetic, and therefore the reader must not be frightened by the symbols, but is asked to make himself acquainted with the short cut to their use provided by the table. The formula is:—

$$\frac{\gamma_{t_1}}{\gamma_\infty} = \left(1 - e^{-kt_1}\right) \text{ and } \frac{\gamma_{t_2}}{\gamma_\infty} = \left(1 - e^{-kt_2}\right).$$

where γ_t is the gamma produced in t minutes and where $t_2 = 2t_1$. In other words we have first to find out by sensitometric tests gammas for, say 5 to 10 minutes development and from these data can find the gamma $_\infty$ and k of the plate for the developer employed. When they are known, the time of development required for any other gamma when using the same developing solution at the same temperature can be calculated from the table B of Mees and Sheppard given opposite. From the general form of the formula

$$\frac{\gamma_t}{\gamma_\infty} = \left(1 - e^{-kt}\right)$$

the required gamma is divided by the gamma $_\infty$ of the plate and the value nearest to the quotient is found in Col. 2. The corresponding number in Col. 1 is the value kt; that is, the time multiplied by the known k of the plate. Dividing by k, the time is obtained. Example:—What is the time of development for a gamma of 0.8 of a plate which (with the same developer at the same temperature) has a gamma $_\infty$ of 1.6 and a k of .15.

$$\frac{\text{gamma req'd}}{\text{gamma}_\infty} = \frac{0.8}{1.6} = .5 = 1 - e^{-kt}$$

From the table, the value of kt corresponding with $1 - e^{-kt}$ of .5 is .700. Dividing by k (=.15), we obtain 4.7 minutes. The method is valid only for developers of Watkins' factor less than 15.

But as a preliminary to this calculation the values of k and gamma $_\infty$ have to be found for the plate and a given developer. The sensitometric method of doing this is to make a series of exposures on two pieces of the plate, develop one twice as long as the other and measure the gamma of each. From the values of these gammas and the times of development the value of k can be found by the table A of Mees and Sheppard. For example, with a plate giving $\gamma_1 = 0.98$ at 3.55 minutes' development and $\gamma_2 = 1.40$ in 7.1 minutes:—

For k, using Table A:—

$$\frac{\gamma_2}{\gamma_1} = \frac{1.4}{0.98} = 1.428$$

Nearest value in table is 1.426, corresponding to a k for 5 minutes of 0.170.

To convert to a k for 3.55 minutes, multiply by 5 and divide by 3.55.

$$\frac{0.170 \times 5}{3.55} = \frac{.85}{3.55} = \underline{0.239 = k.}$$

Gamma $_\infty$ has also to be found, as for example, by the formula of Renwick ("Photographic Journal," April, 1911, p. 213), viz.:—

$$\gamma_\infty = \frac{(\gamma_1)^2}{2\gamma_1 - \gamma_2}$$

where γ_1 is the gamma produced by development for t_1 minutes and γ_2 the gamma produced by development for t_2 minutes, these two times being so chosen that γ_2 is considerably less than $2\gamma_1$ otherwise any error of measurement greatly affects the value obtained for γ_∞. It is possible here only to present in somewhat rough outline the methods adopted in calculations of time of development, but enough has perhaps been said to show the lines which are followed.

Summary.

At this point the foregoing chapters on the elements of the H. and D. doctrine might well end. While they have covered very little ground, the fullness with which the elementary conceptions have been considered will, it is hoped, do something to promote the study of sensitometric methods in the investigation of negative-making and printing processes by a greater number of photographers. Nevertheless, the chapters could hardly be published without one on the basis of the H. and D. speed numbers, the original purpose of Hurter and Driffield's experiments, though perhaps the least fruitful of them. Some explanatory notes on their rating of plate speed are therefore appended.

But the main theme of the present exposition ends here. After defining the theoretically perfect negative—perfect, that is, as a reproduction of the tones of the subject—in terms of opacity, or, alternatively, of density, we have seen the different shares taken in its making by exposure and development.

Exposure such that the difference between any two densities shall be in a constant proportion to the difference between the logarithms of light-intensities producing those densities.

Development such that this proportion shall be 1; that is, that the density-difference shall be equal to the log exposure difference.

We have also seen how this degree of development requires to be varied, and can be varied in a calculable way, according to the printing paper. But there still remain to be considered the rules regulating the effect of temperature and the properties of different developers in the making of negatives of a required specified degree of contrast. This further subject must be left for another occasion, when perhaps it may be possible for it to be dealt with by an authority to whom photographers are largely indebted for the scientific basis of time development.

G. E. B.

(To be concluded.)

FREE-LANCE PRESS PHOTOGRAPHY.—As we point out on another page, the series of articles by Mr. Vining, which begin their appearance in this issue, approach the subject of non-staff press photography from a fresh angle, namely, that of the art editor. The subject, however, is a wide one with many ramifications, and the photographer desirous of making the most of the more ample field which is now open to him is well-advised not to neglect any of the opportunities of obtaining guidance which are available. Undoubtedly the chief of these is the course of postal instruction in press photography which is offered by the Practical Correspondence College, of Thanet House, Strand, London, W.C. We can claim to have been fairly intimate with the value of this course for many years past, and have had opportunities of judging of the eminently practical and constructive scheme of the lessons, and also of the painstaking help rendered to students individually. A recent re-reading of the lessons as issued at the present time impresses us with the College's close appreciation of the conditions in illustrated journalism. It is quite in accordance with the many-sidedness of photography for the illustrated papers that the course of lessons offered by the P.C.C. should cover almost completely different ground from the series of chapters by Mr. Vining which our readers will be able to study during the next few weeks. Between the two the photographer who is ambitious to build up substantial independent earnings in the shape of reproduction fees from the newspapers may feel fairly well assured that there are few ideas or methods of procedure which are not brought to his notice in the most suitable way. An illustrated booklet issued by the Practical Correspondence College and sent free on application gives an excellent idea of the scope of the P.C.C. course and itself provides a certain measure of insight into the practice of press photography, from which so many at the present time are earning considerable sums.

EASTMAN KODAK COMPANY.

The directors' report for the financial year ended December 31 last (the eighteenth full year of business of the company) shows a surplus of $10,330,428 (£2,129,935), after setting off liberal amounts for depreciation and paying 40 per cent. on the common stock in addition to 6 per cent. on the preferred stock. The figure for the surplus in English currency is obtained on the basis of $4.85 to the £ as in previous reports. The above figure for surplus is equivalent to net profits of $18,656,210, equivalent to £3,828,084, the largest in the history of the company, and exceeding those of 1919, which hitherto have held the record, by more than £260,000.

The following table shows the net profits since the year 1903 :—

	£
Year ending December 31, 1903	606,740
,, ,, 1904	688,484
,, ,, 1905	827,610
,, ,, 1906	1,116,639
,, ,, 1907	1,446,479
,, ,, 1908	1,540,725
,, ,, 1909	1,619,087
,, ,, 1910	1,850,552
,, ,, 1911	2,401,910
,, ,, 1912	2,886,401
,, ,, 1913	2,920,090
,, ,, 1914	2,332,579
,, ,, 1915	3,245,600
,, ,, 1916	3,564,784
,, ,, 1917	2,998,467
,, ,, 1918	2,897,313
,, ,, 1919	3,778,595
,, ,, 1920	3,828,084

The report briefly intimates the death of one director, Mr. Alexander M. Lindsay, who had occupied a position on the Board for a number of years past.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, June 20 to 25 :—

Daylight Development.—No. 17,157. Daylight development of roll films. H. G. Chaney.

Enlarging Lanterns.—No. 17,060. Masking-device for lanterns for photographic enlargement. J. G. Kitchen and Thornton-Pickard Manufacturing Co., Ltd.

Shutters.—No. 17,101. Photographic shutter release and counter. F. Sullivan and A. S. Warne.

Finder.—No. 17,304. Focussing-attachment and distance-finder for film cameras. J. H. Whitehead.

Stereoscopy.—No. 17,325.—Stereoscopic lantern projection. P. Ashworth.

Electric Records.—No. 17,106. Photographic recording of electric signals, etc. J. Hettinger and C. A. Vandervell and Co., Ltd.

Stereoscopy.—No. 16,981. Apparatus for viewing stereoscopic cinematograph or lantern-slide projection. A. N. Wight.

Colour Cinematography.—No. 16,756. Optical exposure for three-colour exposure cinematograph. Firm of C. Zeiss.

Cinematograph-Phonograph.—No. 17,033. Means for synchronising cinematographs and automatic musical instruments. L. Köhler and Tonfilm Ges.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Zona.—No. 413,311. Photographic papers. Thomas Illingworth and Co., Ltd., Cumberland Avenue, Park Royal, Willesden Junction, London, N.W.10, manufacturers of photographic papers.

New Materials.

Mounting Boards and Papers.—Messrs. Butcher, Camera House, Farringdon Avenue, London, E.C.4, send us a complete collection of the astonishingly numerous and varied styles of mounting boards and papers issued by them. These include three new introductions designated as the "Gambia," "Vancouver" and "Yukon." They have a certain family likeness, and are all three of them most distinctive styles, for the "Gambia" series is represented by mounting boards which are imitations of close-grained fabric, leather, or wood, and are produced in appropriate colours. The "Vancouver" and "Yukon" papers are perhaps best described by saying that they are imitations of the texture of arras cloth, familiar in the furnishing of studios and picture galleries, but the variety of texture and colour is greater than is obtainable in commercial arras cloth, particularly in the "Yukon" series, which includes two styles of figured gold surface, and in addition a mounting paper of quite smooth gold effect. There are certainly opportunities for making use of these most striking and realistic papers and boards which are a notable departure from the quiet and more subdued tints and textures which characterise the greater number of the specimens which Messrs. Butcher send to us. We cannot help thinking that for the most effective mounting of the great majority of photographs the papers or boards of less striking character are by far the best, but in the three new styles Messrs. Butcher have provided photographers with altogether distinctive goods, and we can well imagine that those who have the enterprise to consider their qualities will find ways of turning them to good account. Samples of any of the materials will be sent free on application to professional photographers.

Commercial & Legal Intelligence.

Legal Notices.—Notice is given of the dissolution, by mutual consent, of the partnership between Frank Spring and Herbert Arthur Bellamy, carrying on business as enlargers and photograph printers at 92 and 94, London Road, Sheffield, under the style of F. Spring and Company. All debts due to and owing by the late firm will be received and paid by Frank Spring, who will continue the business.

Notice is given of the dissolution, by mutual consent, of the partnership between Rose Kate Durrant and Harold Humphrey Brook Durrant, carrying on business as photographers at 37, Fleet Street, Torquay, under the style of R. K. Durrant and Son. All debts due to and owing by the late firm will be received and paid by Harold Humphrey Brook Durrant, who will continue to carry on the business under the same name.

Oswald M. Smith & Co.—Particulars of Oswald M. Smith & Co., Ltd., have been filed pursuant to Section 274 of the Companies (Consolidation) Act. This private company was incorporated in New Zealand on April 16, 1920, with registered office at Dunedin, to carry on business as indent and commission agents and manufacturers' agents, dealers in fancy goods, toys, photographic materials, and other goods. The nominal capital was £30,000, but has been increased to £50,000 in £1 shares. The directors are: E. R. Murphy, H. S. Williams, A. B. Williams, H. B. Williams, C. J. Bennett and O. M. Smith, all resident in New Zealand. The British address is at Copthall House, E.C. N. C. Sawers, of 69, Hervey Road, Blackheath, is authorised to accept service of process and notices on behalf of the company.

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, JULY 12.

Manchester Amateur Phot. Soc. Council Meeting, 6.15 p.m.

THURSDAY, JULY 14.

Hammersmith (Hampshire House) P.S. "Bromoil." H. Procter.

SATURDAY, JULY 16.

Manchester Amateur Phot. Soc. Ramble to Marple District.

ROYAL PHOTOGRAPHIC SOCIETY.

PICTORIAL SECTION.

At the meeting held on Friday, July 1, Mr. Raymond E. Crowther opened a discussion on the rendering of sunlight by photography in the course of a short paper, in which he considered separately the influence of the subject of the photographic process and of the mounting and framing. In the case of open views light and shade played a comparatively small part, and such subjects were perhaps the most difficult from the point of view of imparting the sensation of sunlight to their photographic renderings. But those having a strong foreground provided differences between the high-lights and the shadows, which greatly accentuated the effects of sunlight. The rendering on the plate, in their case, approximated more closely to the psychological effect upon the observer than in the case of an open view.

The ideal photographic medium for the rendering of sunlight was a transparency, for the scale of gradation could be advantageously increased at both ends as the high-light brightness increased the shadows were better penetrated. But when making a positive print on paper the scale was comparatively limited, and one had to choose the best means for making the high-lights appear bright. That meant obtaining the longest scale possible in both the negative and positive, and, therefore, accurate exposure and full but not over-development. As regards the type of negative plate for the rendering of sunlight, it required to be borne in mind that the change in colour of natural objects consequent upon the introduction of sunlight was very marked: it could be readily observed in any of the parks, particularly on grass. Therefore it seemed desirable that the plate should give a record of the colour effect. But sunlight emphasised colours to the eye to which the ordinary plate is blind, and therefore a panchromatic plate, or, as a poor second, an orthochromatic plate, was recommended. But even with a panchromatic plate the sensitiveness of the eye and that of the emulsion do not coincide. To most people yellow, which is frequently encountered in the rendering of sunlight, is more assertive than white. Over-correction, therefore, provided the subjects were suitable, was frequently advisable, but some subjects, particularly skies, would stand it, and Mr. Crowther advised the use of a vision filter, by which the view could be seen as it would appear when employing a given plate and light-filter.

As regards the making of the print, it would immediately be found that a negative which faithfully rendered the luminosity of the subject called for sacrifice at one end or the other of the scale in the making of the print. If the high-lights were retained, the sky would exhibit the effect of sunshine, but the shadows would lack a naturalistic strength. On the other hand, if printing were done for the shadows, the blue of the sky would take a tone suggestive of an approaching storm. It therefore seemed inevitable that the subject should be selected so that when the sky was included it was not necessary to depend on strength of the shadows for effect; or, on the other hand, if the subject depended on shadow rendering it was advisable to avoid inclusion of the sky. Toning of the print through its introduction of luminosity into the shadows would help over some of these difficulties, and a cream base paper, by its suggestion of warmth, was another artifice of value. Mr. Crowther confessed that he saw no objection to local toning or tinting of a print if it contributed to a desired effect.

In briefly referring to mounting, etc., he pointed out a few of the factors which could contribute towards emphasising a sunlight effect.

CROYDON CAMERA CLUB.

The week before last, according to an account kindly furnished to an absent reporter, Mr. A. J. Lyddon, the Principal of the Polytechnic School of Photography, gave a lecture-demonstration on "Finishing Bromide Prints," illustrating his own method of finishing in oils, which is capable of producing a variety of effects simulating chalk, pastel or water-colour.

After a preliminary pun of the "justifiable homocide" class, the demonstrator obliterated the head of a fair damsel on a bromide print with sundry smears of brilliant oil colours, and immediately relieved the feelings of his wondering audience by rapidly reducing this exuberant jazz display to sober monochrome. By means of a mysterious fluid and various brushes and pads, high-lights were then picked out and edges softened in the most dexterous way till a masterpiece of "finish" was revealed.

Colouring came next, the initial proceedings being much the same as before, but apparent purposelessness soon gave way to settled design, and a second triumph of the same order resulted. Finally a bald-headed landscape was fitted with suitable clouds in manner incapable of detection, which furnished the text of a sermon on mud and bromoil by Mr. Harpur. Throughout the proceedings this member, who, so far as is known, has never embarked on finishing bromide prints in manner demonstrated, pointed out several improvements in procedures. The fact that most had been tried by the lecturer and found worthless in no way detracted from the kindly intentions of Mr. Harpur, who is the happy possesser of a battery of brains that cannot be put out of action by big guns, however heavy. A most hearty vote of thanks was accorded Mr. Lyddon for a highly interesting exposition of a somewhat unusual character.

At the start, just as the Secretary was reading the minutes for his own edification, Dr. Mees made a dramatic and quite unexpected appearance, and was heartily greeted by all. Last week he lectured on "Photographic Chemistry," a report of which is held over.

News and Notes.

THE CLUB PHOTOGRAPHER.—The July issue of our Liverpool contemporary is a Hackney number, the contributions, literary and pictorial, being by members of the Hackney Photographic Society.

DR. C. E. K. MEES has received from the University of Rochester, New York State, the honorary degree of Doctor of Science, in acknowledgment of his work in photographic research in the Eastman laboratory.

MR. H. WALTER BARNETT advises us that he is no longer associated with the firm of H. Walter Barnett & Co., Ltd., Knightsbridge, London, S.W., having entirely withdrawn from that firm in March 1920. Mr. Barnett has established himself at Villa Les Tourelles, Dieppe.

MORE COMPETITION.—The proprietors of the new "Sunday Illustrated" offer to supply copies of the pictures appearing in the pages of the paper; matt or glazed enlargements, 6 x 4 in. to 15 x 12 in., at prices ranging from 2s. 6d. to 12s. 6d.; postcards at 6s. per dozen, and lantern slides at 2s. 6d. each.

NEAREST TO NATURE.—Under this title the City Sale and Exchange, 61, Aldersgate, London, E.C.4, have issued an attractive 16 page booklet descriptive of the Richard Verascope camera and of accessories for the viewing of Verascope stereoscopic transparencies in monochrome and colour. The booklet is obtainable free on application.

RÖNTGEN SOCIETY.—At the recent annual meeting, Professor J. W. Nicholson was elected president, and Dr. G. H. Rodman, Sir Ernest Rutherford and Sir William Bragg, vice-presidents. Mr. Geoffrey Pearce, 33, Newton Street, London, W.C.2, was re-elected honorary treasurer, and Drs. E. A. Owen and J. Russell Reynolds, joint honorary secretaries.

CARBRO DEMONSTRATIONS.—The Autotype Company have secured the services of Mr. Dordon Pyke to demonstrate the new and improved carbro process during the autumn and winter. If secretaries of photographic societies wishing to take advantage of this will communicate with the Company details will be sent of the dates when Mr. Pyke will be in their districts.

A Novel Photographic "Finish."—We learn from one of the Birmingham newspapers that on a recent Saturday the East Birmingham Photographic Society had a very enjoyable gathering, first at Aston Hall, where some very good pictures were obtained in the afternoon, and then at the theatre in the evening. Surely a novel sort of finish up for a summer photographic outing.

The Lay Press and Photography.—If the lay papers will have columns of photographic notes, those in authority should see that the information given is fairly reliable. One of last Saturday's provincial papers told its readers that a mixture of "hy-posulphate of soda" and "metal-sulphate" made a good acid-fixer, and that an "amstigmet" lens working at "F 45" was a good one for focal-plane work.

Unreliable Finders.—Unreliable finders—especially finders on very cheap film cameras—are the cause of much spoilt film, and Mr. F. M. Sutcliffe, writing on the subject in the "Yorkshire Post," says that the finder and the film may have had both the same image when the camera left the workshop, but continual uplifting as the camera is opened out throws the finder out of plumb. The obvious remedy is to take as much care of a "moveable" finder as one does of a lens.

London's Water Views.—London is well provided with views in which water forms a part. An artist, writing in the "Daily Chronicle," says that for real prettiness the Regent's Park lake or the view towards Bayswater from the Serpentine bridge takes some beating. The Thames as seen from Greenwich Park looks grander than it does from the Terrace at Richmond, whilst Westminster Abbey and the Parliament buildings can only have justice done to them by those who have gazed on them in the evening from near Lambeth Bridge with the Thames in the foreground. These water views, however, are less "photographic" than some obtainable in St. James's Park—when there is water in the lakes. The view of the India Office across the lake is one of the best in London.

A Link with the Past.—With the death of Lady Brewster a decided link with the past has been snapped, for her husband, Sir David Brewster, was born in 1781. Lady Brewster, who was ninety-four years of age, died on June 22 at Allerly, Montrose, where she had lived since her marriage in 1857, and where Sir David died in 1868 at the age of eighty-seven years. In early Victorian days Brewster was as well known as any great scientist of our own times, and his writings were held in high repute. Among his many inventions were the kaleidoscope and the lenticular stereoscope, he making a special study of the latter. Sir David (writes a correspondent) was a close friend of Fox Talbot, with whom he stayed at Lacock Abbey in 1836, when the sixth meeting of the British Association was held at Bristol.

EARLY STEREO AND MAGNESIUM WORK: AN ALMOST FORGOTTEN PIONEER.

To the Editors.

Gentlemen,—Your "Ex-Cathedra" reference to Prof. C. Piazzi Smyth's "Teneriffe" book, illustrated with original stereoscopic silver prints, is extremely interesting, for although the fact of its publication is fairly well known to those of us who are interested in astronomical matters, it most certainly is not generally known that stereoscopic pictures were included in it. It was in May, 1856, that Prof. Smyth went on his astro-photographic expedition, in the yacht "Titania." He returned in the following October, and published the volume in the spring of 1858.

Our photographic interest in Prof. Smyth, however, does not end here. Seven years later (in 1865) he photographed the interior of the Great Pyramid by the aid of magnesium ribbon, he being the first to do so, and we can but admire his enterprise, as he must have met with very great difficulties in those early days, and it would be interesting to know what became of the pictures. Twenty years ago it was my lot to photograph the very same pyramid's interior, and using the then latest forms of magnesium (powder and ribbon) and lamps, I found the task a most difficult one. I used a ribbon lamp fitted with a kind of parabolic reflector, which enabled me to focus the rays of burning ribbon into the corners of the inner chamber and to project them upon the darker parts of the stone, but Dr. Smyth could have none of these modern inventions, hence his very big difficulties.

Magnesium, I believe, was made known by Davy in 1808, but the first successful photographs were not taken with it until about March, 1864, when Mr. A. Brothers, of Manchester, obtained a stereoscopic negative of a Derbyshire mine. In May of the same year a portrait of Prof. Faraday was taken at the Royal Institution, so that Prof. Smyth may be considered one of the pioneers of magnesium work.

Although magnesium was used for photographic work in the sixties of last century, flashlight work with powders did not come along until twenty years later. It was, I believe, in May, 1887, that Drs. Gaedicke and Miethe first startled the photographic world with the possibilities of magnesium rapidly burnt in the form of powder. To do this they mixed magnesium powder with various oxidising bodies, such as potassium chlorate or nitrate, but this plan of working did not catch on very quickly, and many fatal accidents were reported. Dr. Piffard, of New York, then devised the system of placing the flashlight powder on guncotton, after which—but the exact date I am unable to trace, though I believe it was in 1889—Prof. Schirm, of Berlin, invented the plan of burning pure magnesium powder (not a mixture) by blowing it through a flame, a method largely used in this country about 1891. I do not, however, propose to write a history of flashlight work.

Prof. Smyth also made a careful study of cloud-forms by photography, he doing this in 1888, after his holding the post of Astronomer-Royal for Scotland, and while living in retirement at Clova, near Ripon, Yorks., where he died in 1900. These photographic cloud studies are specially mentioned in books of reference, though I feel sure they are not known in the photographic world.

Those acquainted with the life of Prof. Smyth know of the great interest he took in photography, particularly stereoscopic photography, and I think I do right in describing him as an almost-forgotten pioneer of photography as applied to science.—Yours faithfully,

P. R. S.

MICROPHOTOGRAPHY.

To the Editors.

Gentlemen,—I regret that at the moment I am unable to reply to Mr. J. Rheinberg's criticism and answer his query so fully as I would wish, but I will say at once that Mr. Pigg's micrographic slide was of an advertisement page. He, however, experimented with text pages as well and, I believe, produced promising results. I am now in communication with Mr. Pigg's relatives, who have promised to turn up the actual results if it be possible to do so, and should they, or particulars of them, reach me I shall be able to give names and dates of the actual pages with which experiments were carried out. As, however, ten years have elapsed since Mr. Pigg's death, you will realise that the task of tracing his experiments is not an easy one, but I well remember the results he showed me when visiting his workroom, on which occasion the method of making microphotographs was demonstrated.

Some may wonder why pages of the "B. J." were selected for experiment, and it may be pointed out that the late experimentalist worked in the office in which the "B. J." was then printed. His uncle was the printer and owner of the firm, Mr. Pigg having a laboratory and process business in the same building. When a page was wanted for experiment it was quite a simple matter for him to go into the composing room and take a "pull" of a page on the best plate or calendered paper, specially "inking-up" the type so as to get a clear and perfect page of letterpress for the camera. His results were, therefore, bound to be better than those obtained by anyone working from an ordinary copy of the "B. J.,"

[illegible] printed on the machine in the usual way. It was with [illegible] perfect pages that I saw him at work, and while I am certain [illegible] his success with advertisement pages, I cannot at the moment [illegible] anything definite about the matter pages, though I am of [illegible] that he did succeed in securing a satisfactory result.—
W. T. L.

[illegible] faithfully,

To the Editors.

Gentlemen,—I was very interested in the letter on the above sub- [illegible] by "W. T. L." in your issue of the 17th inst., as I have been [illegible] on the problem for some time.

I am familiar with the small pictures in penholders, etc., which [illegible] still sold in France, and until reading your correspondent's [illegible] I was always puzzled as to how these were made. I have [illegible] these under the microscope, and the grain is very fine [illegible] the detail very sharp, the picture being cemented under a [illegible] glass at the flat end of the lens. From an optical standpoint, [illegible] the lens is very crude, but it is a clever piece of work.

My method of making microphotographs is slightly different [illegible] that described by your correspondent, and may be of interest. [illegible] small precision box-camera is used, fitted with a 4-inch Cooke [illegible] lens in a focussing jacket. The camera is rigidly fastened, [illegible] behind it is a microscope for focussing. This latter is set by [illegible] on the grain of a similar plate to the one being used, [illegible] which the image is focussed on a piece of plain glass of the [illegible] thickness by the rack motion on the lens. The object in my [illegible] was drawn on Bristol board with Indian ink, and measured [illegible] inches across.

I have endeavoured to avoid the use of wet plates, and have [illegible] a good substitute in the Paget half-tone plate, and although [illegible] grain is hardly so fine, the process of making miniature pictures [illegible] simplified.

To get the necessary reduction, the camera is, of course, a con- [illegible] distance from the object, which is illuminated by a group [illegible] half-watt lamps. This process, of course, gives a negative from [illegible] positives may be made by contact printing, using the glue [illegible] process.

It is unfortunate for anyone working these processes that no [illegible] exists to guide one, and the above is the method [illegible] by myself, and others may have better methods which [illegible] should be glad to hear of.—Yours faithfully,

Glasgow, W. W. S. Robinson.

STEREOSCOPIC LENS SEPARATION FOR NEAR OBJECTS.

To the Editors.

Gentlemen,—In reply to the letter from Mr. T. J. Ward re my [illegible] on "Stereoscopic Lens Separation for Near Objects," as [illegible] stated in the article, I have endeavoured to deal with the [illegible] from the practical standpoint and am not prepared to argue [illegible] points of theory.

I suggest, however, that the reason an object 12 inches from the [illegible] of an observer does not appear exaggerated in relief is because [illegible] images transmitted to the retina are influenced to a great extent [illegible] judgment in the same way that although the images are received [illegible] the retina inverted, they do not appear so to the observer. My [illegible] is that if a separation of 2½ inches for an object 12 inches [illegible] gives exaggerated relief (as Mr. Ward admits it does), the [illegible] remedy is to use a smaller separation.

I am quite aware that stereoscopes vary a good deal, and, that being so, it is not possible to give a standard that will be correct for all, but I submit that if the lens separations which I give are used the best all-round results will be secured.—Yours faithfully,

11, St. John's Terrace, Lewes. E. J. Bamford.

July 4, 1898.

A NOTE TO DEALERS.

To the Editors.

Gentlemen,—May we call the attention of photographic dealers and their assistants to the great importance of handing to their customers with all photographic instruments they sell the printed booklet, card or leaflet of instructions which makers almost always supply with such instruments? We have had very frequent instances lately in which buyers have used instruments in quite a wrong way and spoilt their plates or films because the retailer of the instrument has sold it without the printed instructions. We have always regarded full and explicit instructions necessary, and have provided them with all instruments we send out. Buyers should not accept instruments without them, and thus check the carelessness we refer to.—Yours truly, Watkins Meter Co.,

Hereford. July 2. A. W.

A CONTRAST RATING FOR PRINTING PAPERS.

To the Editors.

Gentlemen,—The article by Mr. Rawkins on printing comes, in my humble opinion, at an opportune moment. The question of contrast quality in papers is one that is not at all well enough understood, and printers often wonder why they cannot get the results they want from papers which are made for other classes of negatives only. The fact that some makers' "soft" papers are similar to the "normals" and "vigs" of other makes adds to the confusion, while more than once in a broad experience of papers I have found truly vigorous papers in "soft" boxes.

At the moment I am in communication with a number of makers on the advisability of expressing the actual nature of a paper in numerals, something after the style of the H. & D. numbers on plates. This would be more informative than the terms "soft" and "vigorous," which often are misleading, and, when working with a variety of papers, mean nothing more than "fast" and "slow" would mean with plates. The art of choosing a printing paper for a negative is one deserving of more study by all concerned.

—Yours, J. R. Hall.

Liverpool.

TESTING DEVELOPMENT SPEEDS OF PLATES.

To the Editors.

Gentlemen,—We are all extremely indebted to Mr. Watkins for his very interesting and informative article in the "B.J." of July 1, and to Mr. W. B. Ferguson for having persuaded him to publish his laboratory methods. I hope, however, that Mr. Watkins will not consider that I am not appreciative of his article if I question his statement on page 383, column ii., under the heading "Standards," in which he writes that Messrs. Hurter and Driffield stated that the theoretical steepness of 1.0 gives the same contrast in the print as the original. My memory does not enable me to trace this statement in their papers, and a further search has not revealed it. In their paper on Photo-chemical Investigations, etc., "J.S.C.I.," May 31, 1890, they stated that "A negative is theoretically perfect when the amount of light transmitted through its various gradations is in inverse ratio to that which the corresponding parts of the original subject sent out." This condition is undoubtedly attained by an exposure within the range of correct exposure and subsequent development to a development factor (gamma, contrast, steepness) of 1.0. But Messrs. Hurter and Driffield were considering the *negative alone*, and made no reference whatever to the *print* that it would yield. And it seems obvious that they were well aware that the theoretically perfect negative of their own definition would by no means invariably yield a perfect print, for they wrote subsequently in their paper on the Latent Image and its Development, "Phot. Journal," 1898,* "As we have frequently pointed out, the real control which the photographer has it in his power to exercise lies in deciding what development factor he will reach. By this means he determines the range of gradation of his negative, and adapts the range of light-intensities in his subject to the range capacity of the material upon which he prints. He also modifies the range of his negative in order to adapt it to the printing method he means to employ." It is evident that, even if Messrs. Hurter and Driffield thought in 1890 that a negative contrast of 1.0 was necessary in order to yield a *print* which was a correct counterpart of the subject—and personally I don't think that they ever did so—they had certainly no misconceptions in 1898.

It seems to me that any system of development, whether it be aided by calculation or by judgment, must be able to produce a negative of any gamma at will. The gamma required is calculable from the relationship between the logarithm of the range of light-

* Also H. & D. Memorial Volume, p. 390.

intensities of the subject and the logarithm of the exposure range of the printing paper. If a fixed development factor (gamma) be chosen, such as Mr. Watkins' choice of 0.9, then it will only be occasionally that such a negative will co-relate the subject with the printing paper in a proper manner. We should be very much nearer perfection in development determined by calculation if we possessed and made use of the following information :—

(*a*) The range or scale of light-intensities in the subject.

(*b*) The exposure range or scale of the printing paper.

(*c*) The time of development for *any* gamma calculated from the logarithmic relationship between (*a*) and (*b*).

Hitherto (*a*) and (*b*) have been ignored in descriptions of methods of development, or merely alluded to in the vaguest terms. They are, however, the key to the production of a perfect *printing* negative.—Yours faithfully,

B. J. GLOVER.

Sunnymere,
Birkenhead Road Meols,
July 2, 1921.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. A.—The copyright is yours, and the reproductions are an infringement of it. Better write to the papers pointing this out, and asking what they propose to do.

H. W.—(1) We have found a solution of chrome alum to keep fairly well, certainly six weeks. (2) You would probably be able to procure the caustic soda flakes from Messrs. Hopkin & Williams, Ltd., 16, Cross Street, Hatton Garden, E.C.1.

S. C.—We think that you will find the N. & G. type of changing box quite satisfactory with films. We have used one carrying 24 sheaths, and have had no trouble with it. You would probably require a special focussing screen, as these boxes have a very deep register.

H. E.—(2) It is a good competitive picture, and would stand a good chance in a trade (paper or plate maker's) competition. Commercially it is of little use alone, publishing firms usually buying sets of six. (3) Artistically the plain one is the better, but the toned one would be the better seller.

J. B.—We cannot pass the markings on your prints as *stains*. They are clearly air bubbles caused in some way, probably by rocking the dish too severely, or by carelessly pouring on the developer. If you wet your prints before developing, and make sure that no bubbles exist on the film, we have an idea that your troubles will disappear.

J. B.—The formalities of converting a business into a company are somewhat out of our province, but you can obtain a book on the subject from Messrs. Jordan & Sons, Ltd., 117, Chancery Lane, London, W.C.2, who are publishers of books on company matters, and, we believe, also undertake the conversion of a business into a limited company.

P. W.—Zinc is a very unsuitable material for holding an alkaline developer in regular use, since the soda carbonate steadily attacks the zinc. It is possible that the markings on the negatives may arise from that cause. We advise you to use a tank either of hard wood or of earthenware, ; both Messrs. Kodak and Messrs. Houghtons supply tanks specially suitable for this work.

M. & J.—We regret that without knowing all the circumstances and the quality of the work supplied we cannot help you to fix the price. Such work is usually calculated on a commercial basis ; that is to say, materials, time, use of apparatus, proportion of running expenses, etc., are all totalled up, and a fair profit added to this. If you double the actual cost we do not think you will be far out.

A. H.—The mark something like the figure 8 at the end of the focussing scale is simply to indicate the infinity point—it is not really an 8. The other distances probably indicate metres—a metre is roughly 39 inches, unless, of course, the camera was made for the English market—as many of them are—in which case yards would be indicated. This point can only be decided by trial.

D. E.—Much appears to depend upon the verbal arrangement made, but your charges, we think, prove that you had no intention of delivering the negatives. We may point out that although the photographer has no right to use the negative, save by the customer's request, yet the customer cannot claim it as his property. This position has been upheld in the County Courts over and over again.

E. W.—The distance gauge, or telemeter, is an accessory which is, or was, on the market from several makers, for example, Messrs. Newman & Guardia, 17-18, Rathbone Place, London, W.1. It is simply an instrument for gauging the distance of an object quite apart from any camera. It has never been popular, probably because of the extra trouble involved ; and, of course, those who are regularly using a hand-camera become familiar with judging distances with sufficient accuracy.

H. B.—You cannot do better than use a reflex camera for the work. Any good reflex would serve, and we cannot recommend any special make, the principles of the instrument being the same. An anastigmat lens working at *f*/4.5 would be advisable : though it might not be necessary to always use this large aperture, you would be guided by the definition required, and that seen on the focussing screen of the reflex. Films or plates is a matter of opinion. The choice lies between a supply of dark-slides for plates and a fitting to take flat films in the form known as a "film pack."

A. M.—We would not care to use gas tar or naphtha as a coating for dishes in which prints are to be handled. It might answer for tank development of negatives where the plates are contained in a rack, and do not come in contact with the sides of the tank. For the handling of prints, particularly those to be toned, you cannot have anything better or more economical in the long run than the earthenware dishes. For view work, presumably in half-plate size, about the best all-round camera is a half-plate light model field camera with a good roller blind shutter and a couple of lenses, say, one of 9 in. and another of about 5 in., when it is necessary to work in rather confined quarters.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3193. Vol. LXVIII. FRIDAY, JULY 15, 1921. Price Fourpence.

Contents.

SUMMARY.

No one who looks forward to some pleasant respite from the strain of modern life can help being touched by the truly tragic death of Mr. S. H. Fry, ex-secretary of the Professional Photographers' Association. Mr. Fry died suddenly on the day succeeding his entering upon the tenancy of a country house, which he had at length taken, following his retirement from business a few months ago. (P. 419.)

The appreciation and sympathy of the P.P.A. are expressed in a letter from the secretary, Mr. Lang Sims. (P. 423.)

In his two further chapters on photography for the newspapers Mr. W. Lancelot Vining deals with advisable apparatus and with the plans to be followed in photographing a news event of public interest and transmitting the results to the newspapers. (P. 411.)

The Bristol meeting of the Photographic Convention wound up with a notable visit to Lacock Abbey, the home of Fox Talbot, where a representation was made to the Royal Photographic Society, represented by the president, Dr. G. H. Rodman, of a collection of relics, apparatus and prints, formerly belonging to Fox Talbot. (P. 413.)

Reproduction of a photograph of members of the convention at Lacock will be found on page 414.

The concluding chapter of the series setting forth the conceptions and methods of Hurter and Driffield, is in the nature of an appendix, and deals with the inertia, or inverse measure of speed, of a plate, devised by the two investigators. (P. 415.)

Dr. C. E. K. Mees, who has been making a stay in England during the last few weeks, delivered a lecture on photographic chemistry at the Croydon Camera Club. A partial report dealing particularly with some matters of practical interest, appears on page 416.

In his "Paris Notes," Mr. L. P. Clerc reports a new process of preparing plates specially sensitive to ultra-violet rays, and also describes some Autochrome methods of French workers. (Page 417.)

Considerations of cost, transport and facility of enlarging now tend to limit the size of camera for professional outdoor work to whole-plate. In an article on page 410 we refer to the employment of this size for larger or smaller prints.

Damage to a lens may be visible or invisible on ordinary inspection. The latter kind is more likely to impair the optical performance. Visible defects, such as chips or scratches, or even cracks, are of minor importance. (P. 410.)

The value of a hood for the hand camera lens is much less appreciated than it should be. Some kind of shade, e.g., a flap for box cameras, or a detachable hood for folding cameras, can make a great improvement in the negatives taken under many conditions of light. (P. 410.)

We are glad to see that there are evidences of organisation among painters to stem the tide of futurism, cubism, and the like, which for several years past has been running unchecked. (P. 409.)

EX CATHEDRA.

Carbon in Hot Weather. During the past few weeks the weather has been very trying to the occasional carbon printer, one of the principal troubles being the liability of the gelatine coating to liquefy in the sensitising bath, or even after hanging up to dry. When we consider that it is possible to develop a print in water at 80 degs. Fahr. it is obvious that the tissue must not be immersed in a bichromate bath anywhere near that temperature, nor should it be hung up to dry, except in a cool place. If it be possible to procure ice it is easy to bring the sensitising solution down to, say, 55 degs., and after squeegeeing off all excess upon a plate of glass the tissue may be hung up without much risk. If ice cannot be obtained, a useful dodge is to pour the bichromate solution into a jug or large measure, and to immerse in it a well-corked bottle of a strong solution of hypo which may be made by charging the bottle to one-third with hypo crystals and filling up with cold water. This should be shaken once or twice and put into the bichromate without waiting for the crystals to dissolve. An alternative is to use a spirit sensitiser and to immerse the tissue in this. Applying with a brush in hot weather has in our hands had a tendency to cause streaks, owing to the rapid evaporation of the spirit.

* * *

The Future of Futurism. A new Society of Artists has been formed to let the public have what it likes instead of having to put up with what art-adventurers like to give them. The first annual exhibition of this Society is now open at the Suffolk Street Galleries. As was to be expected, the journalists have not been too flattering about the show. It is, indeed, upon the level of pre-war ordinary work, with nothing superlatively fine in it. But another year may bring better results. The point to be noted is that at last artists have made some organised effort to stem the tide of ineptitude and absurdity which passes by the name of "futurism," "cubism," etc., and we hear rumours that still another Society, with the same objects, is being started. We welcome this effort of painters to rid themselves of the baneful influence of a revolutionary few, who rely upon the "boosting" of Press critics, having nothing else to rely upon. Things have certainly come to a ridiculous pass when, at the National Gallery of British Art, examples of Italian and French decadence are honoured with the cachet of worthiness by being placed on the walls beside the true works of art of our own countrymen. A visit to the Tate Gallery is, in this respect, a truly depressing ordeal, and shows the need of some sort of protest. But in matters of art the public are supreme in apathy, and the sensation-mongers supply exactly the right sort of pabulum for a sensational Press. It is thus that virulence thrives. The great weakness of the New Society is that the painters who comprise it are too

obscure. There are plenty of talented men whose names would have given strength and significance to this praiseworthy movement had they been properly canvassed to support it.

* * *

Damaged Lenses. Considering its reputed fragility it is rather remarkable that so few lenses bearing marks of hard usage are encountered. Such are, however, to be met with occasionally, and it is somewhat difficult for the average photographer to know whether they are worth purchasing at a low figure. Lenses are, as a rule, damaged either by a fall or by careless cleaning or packing. The damage caused by a fall may take the form of a chip or crack or separation of the cemented surfaces. Chips, if not large, do not interfere materially with the performance of a lens if they are covered with black varnish or even opaque colour. Cracks, if not large, may be blocked out in the same way, and even if one of the glasses is broken across it may be cemented together with black cement without showing any sign of the line upon the negative, provided that a very small aperture is not used. A fall may, however, seriously impair the working of a lens without being apparent to the eye. This is when the mount has been distorted and a strain put upon the glass. A general surface dullness, due to careless cleaning with gritty cloths, does not impair the definition, but causes a general fogginess upon the negative. Deep scratches, caused by allowing the lens to rattle about in the camera case, have the same effect, but an improvement may be effected if they are blocked out as if they were chips.

* * *

Fixing Bromides. An experience of one of our readers will probably be of interest to many others. Making a batch of two dozen prints from the same negative, he was much disappointed to find, on taking them into white light to wash, that they were much weaker than they should have been, judging from the appearance in the developer. Being convinced that reduction had taken place in the fixing bath, he made a further print, which he developed to the same depth and fixed for three minutes only. Upon inspection, this proved quite satisfactory, and it was returned to the fixer for a further period of fifteen minutes, at the end of which it was found to be in the same condition as the rest of the batch. The fixing bath contained hypo and meta-bisulphite only, a similar solution having previously worked quite satisfactorily. A fresh sample of hypo had, however, been used for the batch in question, and this probably contained some impurity, the nature of which we do not know. We mention this incident because it may account for uneven depth in a batch of prints, some of which have remained in the fixing bath much longer than others.

* * *

Hoods for Hand Cameras. It is quite an exception to find a hand camera fitted with an effective lens hood, yet it is obvious that if a hood is ever necessary, it is when working out of doors with a lens of large aperture. Although many subjects permit of the use of an unshaded lens, many others have to be passed over, because taking them would necessitate pointing the lens too directly towards the sun, this danger commencing as soon as the direct rays strike ever so little upon the front of the camera. A simple flap, preferably with side wings, can usually be fixed to box-form cameras, which will include the reflex and folding focal plane types, but others, such as folding Kodaks, need a circular or conical hood, which can be slipped on to the front cell of the lens. Whatever type of hood is adopted, the inside should be absolutely non-reflecting, and for a lining, black or very dark-brown velvet or flock paper is the most suitable. Those who desire to construct their own hoods will find much useful information in an article by Dr. Glover in the B.J. for July 30, 1920, while instructions for making a simple folding shade are given by Mr. Mackinnon on page 336 of the current B.J. Almanac. The shade and hood there described folds perfectly flat for the pocket or camera case.

OUTDOOR APPARATUS.

Before the war it was generally considered that the outdoor outfit of a professional photographer was not complete unless it comprised a 12 x 10 camera with its appropriate battery of lenses, a fairly heavy stand, and one or two rather solid carrying cases. In the course of events it has been found necessary to reconsider this choice, and to try to meet present-day conditions. There are now many factors which tend to make the production of large negatives inconvenient and costly, while the facilities for making enlargements indistinguishable from direct prints have been greatly increased. Among other things to be considered is the greatly-increased initial cost of the apparatus itself. Cameras and lenses are at least twice as dear as in pre-war times, and the high price of plates and the difficulty of obtaining the services of an assistant, or even a porter, to help in carrying the outfit, are now substantial factors.

Taking all these points into consideration it seems that the modern equipment should consist of a camera not larger than whole-plate size, which will suffice for direct negatives in many cases, and an enlarger which will take at least a half-plate negative. With such an outfit, not only is it almost as easy to obtain 12 x 10 or even 15 x 12 prints as by the use of large apparatus, but in many cases the finished result will be superior in quality, owing to the ease with which any necessary dodging can be performed. For some classes of work, such as machinery, motor-cars, and any subjects which require blocking-out, the large direct negative has the advantage, but for all ordinary subjects, such as groups, architecture, animals and landscapes, it is no longer necessary.

If possible, the camera should be of the parallel-bellows form, as this is much more convenient for use with a wide-angle lens, and at the same time is more rigid at its full extension than the conical model. Moreover, the risk of cutting off part of the sides of the subject when using the swing-back on a difficult bit of architecture is entirely avoided. A well-made parallel-bellows camera should have a maximum extension of nearly, if not quite, three times the longest dimension of the negative, while it will, on the other hand, permit the use of lenses of very short focus. The lens outfit should include several lenses, ranging from 4 inches to 20 inches in focal length. If cost is a prime consideration only the smaller ones need be anastigmats, rapid rectilinears being quite satisfactory for any focal length above 12 inches. If a separable lens of 8½ inches, the single components being 12½ and 17 inches, be chosen, this will make a good basis. In addition, a wide-angle lens of 5½ inches, which may be of the rectilinear form, and an anastigmat or good rectilinear of 10 inches focus will give a fairly complete set. The separable lens should have a maximum aperture of $f/6$, but for the others $f/8$ is as large as is necessary.

As absolute sharpness is a *sine qua non*, the tripod should be fairly solid. The ordinary self-locking style

with an 8-inch head is quite satisfactory, and a folding base which will strap up with the legs is a most useful accessory, especially for indoor work. An illustration of this accessory will be found in the "Practicus" handbook, "Commercial Photography," issued by our publishers.

Three double dark slides with carefully adjusted inner carriers for half-plates are requisite, and it is a good plan to have a half-plate Mackenzie-Wishart slide, with at least half a dozen envelopes adapted to fit in register with the regular focussing screen.

The reader will probably have gathered that the idea is that the negatives for all orders above whole-plate size should be taken upon half-plates from which the enlargements are to be made, and as the degree of enlargement is only two diameters for 12 x 10 prints, and two and a half for 15 x 12 prints, there need be no apprehension of want of sharpness, nor of granularity, if plates of moderate rapidity be used.

The enlarger, if fitted with a condenser, should have one of 8½-inch diameter, so that the plate is evenly illuminated to the corners, and it is advisable to interpose a piece of finely-ground glass between the light and the condenser. This equalises the illumination and prevents any small scratches or defects on the film or glass from being emphasised. A good front lens should be fitted so as to secure perfect marginal definition at full aperture. The 8½-inch anastigmat would answer perfectly, but there is a slight risk of the balsam being injured by continued heat. For this reason a lens of the Cooke type, which has no cemented surfaces, is to be preferred.

If the dark-room arrangements permit, a very effective enlarger may be made by enclosing a couple of half-watt lamps, of about 500 c.p., in a well-ventilated box, so that they illuminate a sheet of white card, which serves in lieu of a condenser. The ordinary lens may then be used without any risk, and the results obtained will, as a rule, be superior to those obtained with the aid of a condenser. It is an excellent plan, where practicable, to fix the negative in an opening cut in the wall of the dark room and to have the lamps and reflector outside.

It will be a great saving of time if the enlarging apparatus, of whatever form it may take, is carefully calibrated for the sizes mostly required, so that only a slight adjustment for sharpness is needed, that is to say, there should be clearly-defined positions for the negative lens and paper for, say, 15 x 12 or 12 x 10 prints. A great advantage of reflected light as the illuminant is that it is as easy to enlarge from a whole plate as from a smaller size.

To secure reasonably short exposures on enlarging it is necessary that the negatives should be free from any trace of yellow stain. This condition can be secured by using freshly-made pyro solution containing an adequate amount of sulphite, while the question does not arise when metol-hydroquinone, amidol or Azol are used for negative development. Care should be taken to avoid excessive density, as rather thin, bright negatives yield the best enlargements.

PHOTOGRAPHY FOR THE NEWSPAPERS.

[Below we continue the publication of a series of eight chapters on the supply of photographs to the newspapers written by Mr. W. Lancelot Vining, until recently art editor of the "Sunday Pictorial." So far as we know this is the first occasion on which the subject has been dealt with by a writer intimately acquainted with the production of an illustrated newspaper, and considering the matter from the angle of the art editor. Mr. Vining, who has spent his life in press photography, first as a free-lance and subsequently as a press photographer on the "Daily Graphic" and "Daily Mirror," deals in the current chapters with the choice of suitable equipment for press photography and with the handling of a news event of public interest. His articles will appear further in our issues of July 22 and 29.—Eds. "B.J."]

III.—APPARATUS.

I often receive letters from the readers of the "Sunday Pictorial" asking me to tell them the best kind of camera to buy for press-work, so I intend to give a chapter to this subject.

Any camera which will turn out a good photograph can be used for press-work, but certain types of cameras will naturally limit the field of work. I do not know of any camera which will do every kind of work that may be required. Police Court work requires a special camera. This must be very small and have a very fast lens, but as there is not a great deal of work of this description I do not think we need worry over these subjects.

The ideal camera is one using 5 by 4 plates, a very good lens working at *f* 4.5 and having a focal-plane shutter, a long focus lens which can be used instead of the *f* 4.5, and plenty of slides. We will suppose that we have just bought a new one having the above features. First of all, you must get to understand the working of the shutter, and the changing of the speeds. This can be done at home and without exposing any plates. It is quite useless to start taking photographs until you have thoroughly mastered the shutter, and here a word of warning all focal-plane shutters must be handled with care. Read the maker's instructions very carefully, and, if possible, get someone to demonstrate it to you. Having mastered the shutter, the next important thing to do is to make yourself perfect in judging distances. The ones you must be able to tell at a glance and not be more than a foot out are 3 yards, 5 yards, 7 yards, 10 yards, 15 yards, and 25 yards. You can practise this while out walking any time. Select an object ahead of you, guess the distance, and pace it out. You will soon find that you are quite good at it. This distance-judging is very important, because your lens is in a focussing mount with a scale in yards, and you must be able to set this scale and take your photograph without using your focussing screen. There is no time for this in the majority of events. Of course, there are others when you can use a tripod and focus in the ordinary way. I am not a lover of the reflex, except for certain special work, and then it cannot be beaten. It is not a good type of camera for work in the street. I found that once your head was in the hood you were very liable to miss something going on near at hand, and people often stepped in front of the camera as exposure was being made because I had not seen them coming. There is nothing very difficult about using the small wire frame view-finder, and by experimenting this can be fixed so as to give the exact view that will be given on the plate. The speeds of a focal-plane shutter usually range from one-tenth to one-thousandth, and it is very important to be able to hold the camera quite still when working at the lowest speed. A focal-plane shutter should run smoothly without the slightest jar, otherwise sharp results at one-tenth will be out of the question.

I have described a camera which can be used for nearly every type of subject, but quite 50 per cent. of the work could quite easily be done with an ordinary plate or film camera. Take any issue of an illustrated paper, and you will find that by far the greater number of the photographs it contains did not require a speed greater than one-hundredth. The focal-plane shutter is only a "must" when you are going in for high-speed work, but remember when buying a new camera that the focal-plane is more efficient than the ordinary shutter in lens mount, etc., and this applies at any speed.

I have made a point of the types of cameras because so many people are under the impression that the camera must be one which is made and sold especially for press-work, but this is not so. But, if any of my readers are thinking of taking up illustration work, and are about to buy a camera, they should certainly get the best one possible, so that they can tackle any subject that comes their way and not be restricted by unsuitable apparatus.

I have myself used all types and sizes of cameras, and these have ranged from the very smallest Block-note to one which was a specially-built half-plate reflex, and carried a 36-in. focus lens working at *f*/6. The extension was over 5 ft., and I used it mostly for cricket matches to secure play pictures. This camera always required two men to carry and work it, one to expose while the other kept the interested crowd back, and a car was required to move it from place to place.

Now, just one word with regard to exposure. A golden rule is to give the longest exposure possible that will give a result free from movement. (This speed can only be judged by experience.) By doing this you will very often find that you will be able to use a smaller stop, getting a great depth of focus and a result which will stand a great deal of enlarging, and that is often very useful in press-work.

Now, let us look at the vexed question of plates or films, and although my vote must be given to plates, I do not for one moment say that films are of no use for photographs required for publication. Plates are very much faster than films, and up to the present time film makers have failed to produce a film with the speed of the fastest plate. Also plates are very much easier to handle either wet or dry. An art editor would much rather hear that half a dozen plates were arriving from a correspondent in preference to a 6-exposure roll of film. Plates can be dealt with more quickly, and then enlarged while wet, with very little fear of damage or failure, and each plate can, if required, receive special treatment. Films can only receive special treatment if they are cut up, and then their curl is very awkward. Enlarging them whilst wet is a difficult process, and the risk of damage to the film surface is great. Yet with all this against films, some of the greatest "scoops" amongst modern photographs have been obtained on films, so never refrain from using them. I have heard of one or two cases where photographs of an event were not sent in because the photographers were under the impression that films were no good for "rush" work.

The type of negatives to be aimed at if you are developing the plates yourself is one full of detail. Contrast must depend on whether you are going to contact-print or enlarge. With regard to developers for both plates and papers, always use the formula recommended by their respective makers. They know what is in the emulsion, and you will always find that their developers give the best results.

When setting out to cover an event for a newspaper always carry a tripod, which may be quite a light one, but which you will find you require far more often than you anticipated. If you are wise you will use it on every possible occasion and get the sharpest possible result.

IV.—THE BIG NEWS STORY.

This chapter will, I expect, be considered the most important, so I will make it as complete as possible.

I am going to suppose that some big news event has suddenly happened quite close to you. It does not matter very much what we take as an example, because, whatever it is, it is the treatment of it that is going to count; but it is the type of event which is quickly known all over the country and appears in all papers as the big story. All art editors will be wanting photographs in the quickest time possible, and you were lucky enough to be on the spot, or you live near enough to get there very quickly. First of all, get hold of a "Bradshaw" or "A.B.C.," and work out the earliest train you can get plates on or think you can. Then send the art editor of the paper you are going to send your plates to the following wire:—

"Covering the accident at Blank. Hope to put plates on 4.30 train, due Euston 9.10. Wiring later."

This wire is important, because it tells the art editor four things. 1st, that the event is being covered; 2nd, he can, with luck, expect plates at a certain time; 3rd, they will be undeveloped, so he will arrange that when they arrive the night printer is in the dark room with developers and enlarging lantern ready, instead of perhaps the printer being out at supper, which would mean precious time being lost; 4th, he can be sure of another wire giving the exact train that plates are on.

If you are on the spot, or very near, you will not have any worry about reaching the scene quickly, but I just want to suppose you are twenty miles away. In this case you may have to decide between using a car or waiting two hours for the next train. Now these two hours are of the utmost importance, and may mean an earlier train for sending the plates to London. A paper is always willing to pay the reasonable expenses of a correspondent working for them on a big story. If you are ...g it off your own bat, and are fairly sure you will be first, ...ld risk the cost of the car, as it may mean a great deal ...o score over your rivals on a big story.

... now on the spot, and you may find that it is not at all easy to get pictures, or even get very near the scene. The police may have formed a guard around the spot; if your application to get a little nearer fails, don't get cross, it is fatal. Try the inspector in charge, and if that fails then you must try to outwit the guard, and you will want to use all the brains that you are blessed with. These situations do occur, and this is when the long focus lens often scores heavily. Expose your plates with great care, and write out a caption or title, and number this to agree with the number on the dark slide. Be sure you give plenty of details. This is most important, and be very careful how you spell names, and be sure that initials are correct. Don't spare any plates, and be sure to illustrate all sides of the story. A real big news story always wants well covering, and you never can tell how many pages are going to be filled with it. Having obtained your pictures, make for the station, remembering that on the way you must pack your slides, and, if possible, in a wood or tin box. If you are continually sending slides away, the best plan is to have a few of these boxes at home, and take one with you on the big story. Sometimes when the accident, or whatever it may be, takes place out in the country it is very difficult to get a suitable one, and your plates run a great risk of getting broken. The type of box favoured by press photographers can be obtained at most sweet shops. I think they are 7 lb. chocolate boxes, and when empty can be bought for 2d. I remember on one occasion having to purchase the contents as well as the box, as there were no empty ones available and I had to have one.

Not nearly enough attention is paid to packing glass plates, although every photographer must realise that all his work will be wasted if his plates reach the newspaper office broken, and this would not have happened (as it often does) if he had expended a little care while packing them. Use plenty of paper around the slides, and see that this packing is tight enough to prevent the slides moving about in the box. You never can tell what will happen to the box once it has entered into the gentle care of the railway company. Let us suppose that it is quite impossible to get a box of any description.

Obtain three or four newspapers—the ones containing plenty of paper in them, such as the *Times* or *Telegraph*, and pack the slides in these. I have had to do this several times, and my slides arrived at the office undamaged, but with this method they run a great risk. Address your box on the following lines:—

RUSH. GLASS WITH CARE.

To *THE SUNDAY PICTORIAL*.

EUSTON STATION.

By 2.10 train. TO BE CALLED FOR.

Try and reach the station at least ten minutes before the train is due to start, so that you will have ample time to get your parcel booked. Take your parcel to the outward goods office, and have this done. Pay the carriage at your end, as it will save valuable time upon arrival. Ask the clerk to let you take it down to the guard's van yourself. He will very likely let you do this if he knows you and what your work is, but if he refuses I advise you to hang around and keep your eye on the box and make sure that in the rush it is not left behind. They have a nasty habit of doing this in certain parcel offices I could mention. Make a point of finding out the guard and drawing his attention to your box, and give him a tip. This is very important when your box has to change trains at a large junction, but once you can get him interested, you can feel fairly sure that your plates will get through to time, or, at least, not miss a connection. Directly you have seen your plates starting on their journey, send a wire to the art editor of the paper as follows:—

"Undeveloped plates of accident at Blank arrive Euston 9.10, with rear guard; return slides at earliest."

Sign your name and address. If you know for certain that you were the only photographer there, state it in the wire by the word "exclusive," but do not put this unless you are quite sure of the fact. Once the wire has been sent the work passes out of your hands, and you are free to decide whether there is more in the story for you to illustrate. The local evening paper may be out by this time, with names and addresses of the killed and injured, and incidents will be given which can often be illustrated. If the story is a big one, it will always pay you to collect one or more portraits, as well as returning to the scene and getting some quite different pictures from those you have already sent off. The collection of portraits of people who have been killed is not at all pleasant work, but it is often very important and requires a great deal of tact, and the greatest care must always be taken to ensure the correct names being on the back of the photographs, otherwise serious trouble is sure to follow, which may end in the law courts, and result in heavy damages against the paper, and then you will become most unpopular. Another end of the story is to visit any of the injured that are well enough to be seen, either at their homes or in hospital. Photograph them, and take down any story they may have to tell. You will often get ideas for other pictures from them. Try and find out what caused the accident, and if any persons are connected with it try and photograph them or collect a studio portrait. In a recent rail accident there were three important portraits connected with the cause of the smash, but they did not reach London for some days. The length of time that interest will last in any big event depends on the public, but on a real big story you need never be afraid of sending too much stuff. Never waste valuable time developing your plates. Every picture paper runs a staff of experts, and what they cannot get out of your plates no one else can. If you are working for a local paper at the same time, duplicate your exposures as follows:—

Take two of the same view, on 1 and 3, 2 and 4, 5 and 7, 6 and 8, then you can keep slides 1-2, 5-6, giving you four pictures for the local paper, sending 3-4, 7 and 8 away, or if you have time before the train leaves, and can get to a dark room, take the plates you are sending away and put them in an empty plate box, film to film, fill up with paper, and carefully pack this box in the wood or tin one, just as you would have done your slides. When doing this be sure to number your plates in the corner to agree with your titles. A copying pencil is best for this, and be sure you don't forget to put the titles in the box. It is very easy when in a hurry to forget them, and I regret to say that this very often happens.

We will now suppose that the occasion will arise when you reach the station with your parcel within a minute or two of the departure of the train and you have no time to book. Find a passenger going to London, or to whatever town you are sending your plates, and ask him or her to take it and give it to a taxi-driver to deliver at the office. Ask them to tell the driver that his fare and tip for quick delivery will be paid upon receipt of parcel, but be sure if you do this you mention it in your wire. I have done this dozens of times, and have very rarely met with refusal, and this is the only way to get quick delivery from abroad. I can remember being let down only once when employing this method, and that was when I was over in Paris for the *Daily Graphic* at the time of the great floods some eight or nine years ago. After my first day's work I went to the station in the evening with other London photographers, and we each found a passenger to bring our slides. Mine was coming to the Hôtel Cecil, so I wired the office to call for them at 10 a.m. the following morning. When my man reached Calais he found a very bad storm raging, and it can be very bad in this quarter, so as he was a very bad sailor and in no hurry to reach London, he waited for two days until the storm had blown itself out, and my slides (packed away in his bag) waited with him, while the office sent around to every hotel in London, and then sent me a series of telegrams which I would not like to print here.

I have given you a very fair account of how a press photographer would carry out a really big story, and if you are ever lucky enough to work one, and proceed on these lines, you will not go far wrong.

W. LANCELOT VINING.

(To be continued.)

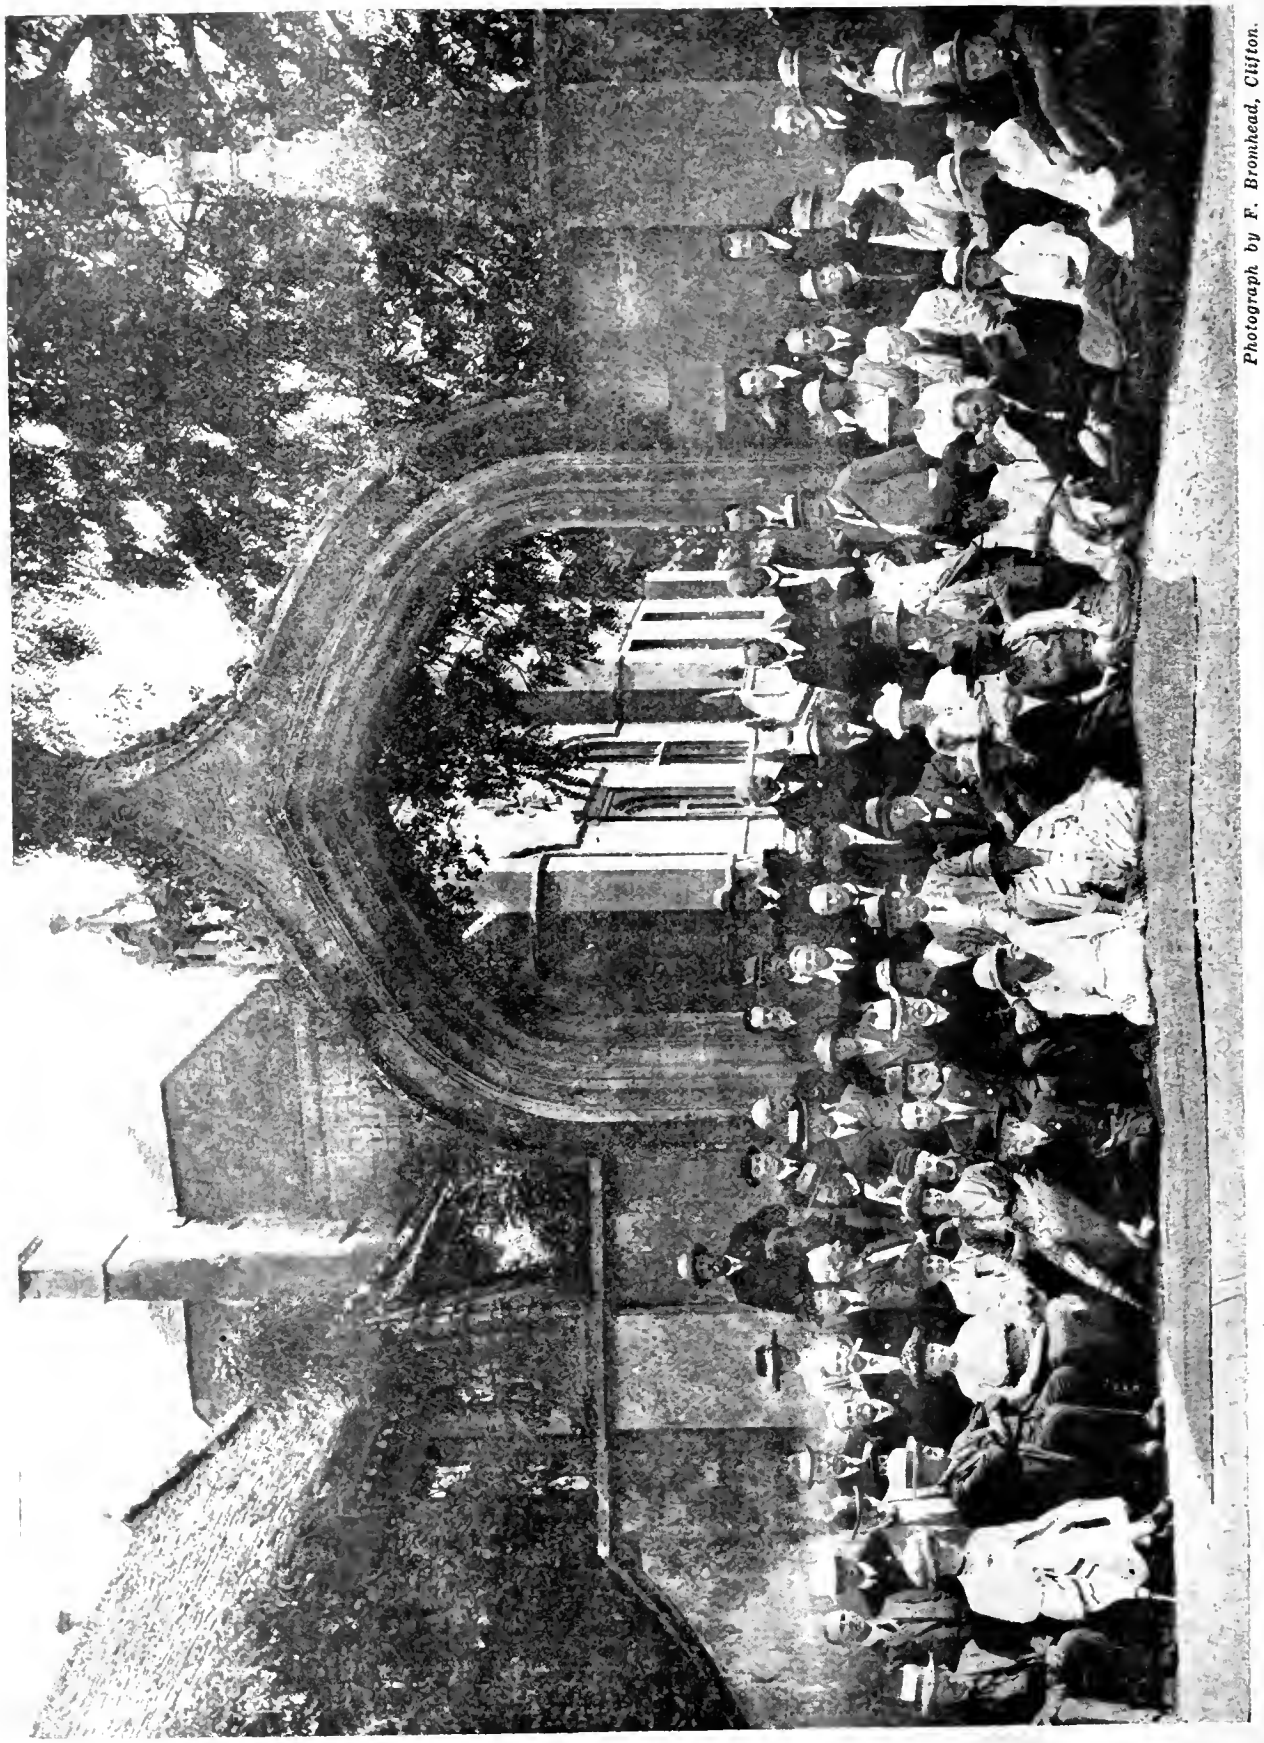
PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

Last Friday's proceedings of the Photographic Convention were, perhaps, the most notable of the week, for they included a visit to the village of Lacock and to Lacock Abbey, the home of William Henry Fox Talbot and the scene of his historical experiments in photographic processes.

Following a visit during the morning to Bath, the party proceeded after lunch by char-à-banc to Lacock, where they were received by Mr. Foley, agent for Miss Talbot, the granddaughter of the pioneer. Lacock is a picturesque abbey, founded in 1232 by Augustinian Canonesses, and the members of the party found many most interesting subjects in the cloisters and conventual apartments. In the nuns' day room the only fire in the abbey was kept burning, and the room still contains a huge brass cauldron, cast in 1500, which is supposed to have been used for cooking operations.

But the chief interest of the visit centred first in the exhibition of apparatus used by Fox Talbot and of examples of the results obtained by his processes of photography and photo-engraving. These had been arranged by Mr. Herbert Lambert, of Bath, to whom members interested in the historical side of photography could not be sufficiently grateful.

Afterwards, gathered in a corner of the grounds, a further interesting ceremony took place, namely, the handing over of the collection to the Royal Photographic Society for pre-



Photograph by F. Bromhead, Clifton.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM, JULY 4 TO 9, 1921.

GROUP OF MEMBERS PHOTOGRAPHED AT LACOCK ABBEY, WILTSHIRE, THE HOME OF WILLIAM HENRY FOX TALBOT.

servation in the museum at Russell Square. Mr. Foley, who apologised for the unavoidable absence of Miss Talbot, formally asked the acceptance of the Royal Photographic Society of the collection, which he was glad to think would find a permanent home for the benefit of succeeding generations of photographers and as a form of memorial to the English inventor.

Dr. Rodman, president of the Society, said he was exceedingly proud to thank Miss Talbot, through Mr. Foley, for her gift. For many months he had taken a special interest in getting together apparatus relating to the history of photography as a permanent exhibition in their museum. When he heard, through Mr. Lambert, that there was a desire on the part of Miss Talbot for her grandfather's apparatus and prints to be made more accessible than could be the case at Lacock, he felt that the collection should be preserved at the house of the Royal Photographic Society, and he was very glad to witness the consummation of his hope. He cordially thanked Miss Talbot and also Mr. Herbert Lambert, who had devoted a great deal of time to arranging the exhibit, and had kindly consented to prepare it for transport to London.

After exploring the village of Lacock and taking tea there, the party returned by road to Bath and thence by rail to Bristol, where the final fixture of the Convention week was held in the shape of a lecture by Mr. C. P. Crowther on "The Making of Portraits."

The fine weather which prevailed throughout the Convention week, perhaps in excess when one has to experience the gradients of many of the thoroughfares in Bristol, conspired with other circumstances to promote a most successful and enjoyable gathering. Mr. Bothamley, it need hardly be said, proved an ideally genial president, and under the organisation of the honorary secretary, Mr. F. J. Mortimer, the machinery of the arrangements for the meetings and excursions functioned with extreme smoothness. As briefly announced last week, the choice for next year's meeting lies between York and Shrewsbury. The Convention held its meetings at Shrewsbury in 1895, but has not previously assembled at York. On this account the balance of preference naturally tends to swing in the direction of the Yorkshire city, and a further reason for favouring the latter venue is the well-organised ring of photographic societies existing within the Yorkshire Photographic Union, the collaboration of which body in the arrangement of a Yorkshire Convention would, no doubt, be heartily given.

On another page we reproduce a photograph of members of the Convention, taken in the grounds of Lacock Abbey immediately after the presentation of the Fox Talbot relics. The group was photographed by Mr. F. Bromhead, of Clifton

THE H. AND D. DOCTRINE.

The present series of chapters, aiming to set forth in simple language the conceptions and methods originated by Hurter and Driffield, might appropriately have been ended with Chapter IV., which appeared last week.

It was there shown that the time of development, and the gamma or contrast of a plate which has been exposed within the period of correct exposure, are related in a definite though mathematically complicated way with the time of development.

For a plate of given maximum gamma and for a given developing solution the time of development, for a given gamma, depends upon a particular property of the plate, namely, the "velocity constant" denoted by k.

The tables calculated by Mees and Sheppard for the simplification of the mathematical formula were given last week. At the wish of several experimenters, these tables have been reprinted on card, and a copy will be sent to any applicant enclosing stamps for their transmission by letter post

The present chapter, while not exactly forming a part of the scheme of the earlier ones, is added for the purpose of illustrating the basis upon which Hurter and Driffield founded their method of expressing the speed of a plate, by the so-called H. and D. No.

V.—INERTIA—THE H. AND D. INVERSE MEASURE OF SPEED.

Although the finding of a means of measuring the relative speeds of plates was the main object of Hurter and Driffield's researches, we have left this outcome of their work out of consideration up to this point in order not to introduce a side issue into the foregoing presentation of the theory of making a negative which correctly reproduces the light-intensities of the subject. We can now turn to see how the H. and D. measure of the speed of a plate is obtained.

If in the diagram (fig. 6) of the characteristic curve of a plate, the straight correct-exposure portion be produced to cut the log exposure scale at a certain point, the distance (representing so many candle-metre-seconds) of that point from the zero of the scale is termed the *inertia* of the plate. The inertia thus measured is an exposure—the exposure which marks the beginning of the period of correct exposure—and therefore it is inversely proportional to the speed of the plate In other words, the greater the inertia, the less the speed of the plate, and *vice versa*. In order to obtain numbers which are direct measures of speed, the value found for inertia is divided into a factor, which for the standard candle used by Hurter and Driffield in the exposure of their test plate was 34. Thus, for an inertia of .51, $\frac{34}{.54} = 63$ = the H. and D Speed No. of the plate. If a stronger light-source is used for the exposure of the test-plate a proportionately greater factor requires to be used instead of the 34.

The precise significance of the inertia value as a measure of the slowness of a plate (and therefore, inversely, of its speed) is somewhat difficult to define. It does not measure the smallest exposure which a plate can receive in order to yield some kind of a record of a series of light intensities which have acted on it. On the other hand, it does not measure the maximum exposure which a plate may receive in order that the resulting densities, first latent and subsequently developed, shall show differences proportional to the differences between

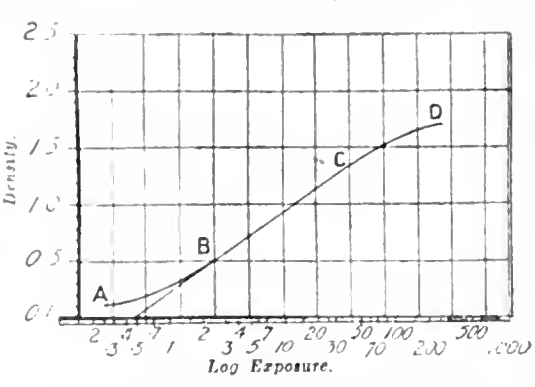


Fig. 6. The Characteristic Curve of the Plate.

Densities are plotted against the logarithms of the exposures which respectively produce them. The straight line portion B C is the period of correct exposure. The point at which, when produced, it meets the log E scale, marks the distance on the log E. scale, which measures the inertia or slowness of the plate.

the logarithms of corresponding light-intensities, that is to say, shall yield a straight-line curve. But it measures an exposure between these two, viz., the minimum exposure within the straight-line part of the curve, and was chosen by Hurter and Driffield on account of the definite and simple manner in which it is ascertained by impressing a series of exposures on a plate and plotting the resulting densities against the logs of the exposures.

In their mathematical investigation of the properties of an ideal plate, Hurter and Driffield evolved a formula for inertia depending only on the values of two densities and on the logarithms of the exposures producing them. That formula applies to a plate the curve of which is one straight line; and thus in the case of an actual plate applies only to the straight-line portion. The above construction (producing the straight-line part of the curve to the log exposure axis) is exactly an easy graphic method of working out the formula. At a stroke it shows the result of two multiplications, two subtractions, and one division. The inertia, and therefore the H. and D. No., thus neglects the under-exposure part of the curve, and hence may be looked upon as a measure of speed which rates the plate slower than suffices for passable results in practice, if one is prepared to forgo correct reproduction of the light-intensities from the subject. Still inertia, as defined by Hurter and Driffield, does not indicate a speed which is the best possible for correct representation. It is contrived to indicate the exposure at about which correct representation begins. A method of measuring speed on the basis of the exposure for the middle of the period of correct representation was considered by Hurter and Driffield, and has been put into practice by Mr. Watkins, who applies the name "central speed" to its findings.

While Hurter and Driffield recognised the somewhat arbitrary measure which their inertia represents, they held that, provided the developer does not contain bromide, the inertia is independent of the various variable factors, such as time of development, different developers, if their method of determination be strictly followed. In their last paper Hurter and Driffield admitted that different developers would, in some cases, give different speeds, and later experiment by others has shown that differences may arise, chiefly in consequence of the variation in inertia according to the gamma to which a plate is developed. In this respect different developers greatly affect inertia, so that 30 years after Hurter and Driffield's first publication of their method we are still without a rigid method of measuring the inertia or speed of a plate.

Fog.

With the object of simplifying such account of sensitometric methods as has hitherto been given, no reference has been made to the fact that the silver deposits, measured as opacities and expressed as densities, are not solely the result of the action of light, but include also deposit produced by the developer, and that (a very small quantity) resulting from the glass and the gelatine coating. It is customary in all such measurements to include on each test-plate a portion which receives no action of light, and to deduct the density obtained on this part from the other density values, on the assumption that this so-called "fog" is present in the same quantity in each density on the self-same plate. Characteristic curves and other results are then plotted from these net densities, *i.e.*, exclusive of fog.

But it may be objected: though we deduct fog from our density values, the fog exists in the negative which is used; the behaviour of the latter, *e.g.*, in printing, may not therefore be in correspondence with the indications of the characteristic curve or with data derived from it. If, however, this apprehension has arisen, a re-reading of what has already been said should disperse it. Providing that the fog *is* uniform—and methods (of obtaining the characteristic curve) which dodge fog deduction indicate that it is, at any rate, approximately uniform—the presence of a uniform deposit over the densities of the negative means that the transmissions of all the deposits are proportionately reduced. The transmitted light-intensities are feebler but relatively the same; in other words, the negative is slower in printing. The effect of the fog is that of putting a sheet of tissue paper in front of the negative in the printing frame. G. E. B.

PHOTOGRAPHIC CHEMISTRY.

[Abstract of portion of a lecture given on the 19th ult., by Dr. Mees, at the Croydon Camera Club, and discussion following it.]

As mentioned last week, Dr. Mees gave a lecture on "Photographic Chemistry," which covered wide ground, from a brief consideration of the chemistry of emulsions to the final washing of the negative. In the opinion of the most hoary-headed or effulgent-topped veterans the lecture was deemed to be the finest popular exposition of a scientific subject ever given in the club. Much of the interest aroused related to experiments conducted, and diagrammatic and other slides shown, without which only an inadequate idea can be gathered of the lecture as a whole. Despite the "off" session the room was crowded, with not a few of Kodak notabilities present from both sides of the Atlantic, including Messrs. Crowther, Luboshey, Pledge, Stinchfield, and Wratten.

A thorough knowledge of the subject; the ability in the fewest possible words to convey clearly that knowledge to non-technical minds; the judgment to know what to omit or refer to but briefly; and a keen "showman" instinct, are all factors which in combination make the ideal lecturer and are fully possessed by Dr. Mees.

He started by saying that the majority of photographers, professionals or amateurs, stand in need of a knowledge of photographic chemistry, and many present would be interested to hear something new—namely, facts.

If a solution of sodium bromide be taken, and a solution of silver nitrate is added to it, a curdy precipitate of silver bromide forms which sinks almost instantly. To obtain a permanent suspension of the silver bromide something else must be added, gelatine usually being employed. A so-called emulsion is made by adding a solution of silver nitrate to a solution of gelatine and bromide. It might interest his fellow members to hear that in the preparation of gelatine the finest product is used for photographic purposes, the lower grades being marketed for cooking purposes.

With its sponge-like texture gelatine has many unique properties. Chemicals have various solubilities, usually dissolving more freely in hot solutions, which if super-saturated will on cooling result in a proportion of the solids separating out. Gelatine is absolutely insoluble in cold water, and indefinitely soluble in warm, and on cooling nothing separates out, the combination setting to a jelly. By diagrammatic slides he illustrated the reason for this, and also the peculiar action of a cube of gelatine which, when immersed in water, swells but little sideways and very considerably upwards. When allowed to dry the edges harden first, resulting in a skeleton framework, and in consequence a curious distortion of the cube.

Similarly, when a drop of water falls on a dry negative the gelatine swells, and the outer boundaries setting first draw the silver grains away from the interior, rendering it the poorer. Hence the familiar transparent spot surrounded by a, more or less, opaque ring. In answer to a question, the lecturer said there is no known method of removing such a mark, but its formation may be prevented by immediately immersing the negative in water when a drop falls on it.

The various degrees of "swellibility" of gelatine in neutral, alkaline, and acid solutions, were next described, and a caution was uttered against plunging a negative straight from a strongly alkaline developer into an acid-fixing bath. This imposes a strain on the gelatine film, with a danger of its stripping from the glass.

Many theories, he said, have been advanced as to the constitution of the latent image (one theory being described by means of

diagrams). But of whatever nature the latent image may be, it undoubtedly consists of silver bromide which owing to light-action is developable. With developing papers and P.O.P. the energy required to produce the final picture is about the same. In the case of the former the energy derives but little from light-action, whilst with the latter light-action plays a predominant part.

Three great steps in the history of the world, he thought, contributed mainly to the advancement of mankind:—The domestication of wheat; the reduction of iron from its ore; and the production of movement by steam. The fourth, yet to come, will be the release and control of atomic energy.

Without reduction photography would be impossible, but a restrained and domesticated sort of reduction is required (which is fulfilled by developers ordinarily in use), since it is necessary that only the silver bromide which has been affected by light shall be reduced. The reduction of silver nitrate solution to a finely divided precipitate of metallic silver was prettily shown by the addition of a solution of ferrous sulphate.

A short reference to the "benzene ring" followed, with a brief consideration of standard formulas for developers, which are not necessarily the best for all classes of work. The number of formulas in existence, he said, is somewhat astonishing at first sight, but is not so great as it appears, for thanks to the British system of weights and measures, identical formulas per unit of developer may appear to differ by the adoption of varying bulks of solution.

Developers may be of high, or low, reduction potential. The lower the potential the greater the restraining influence of bromide, and *vice-versa*. In ordinary work a happy mean is desirable, which is fulfilled by pyro, or metol tamed with hydroquinone. The last used alone has a very low reduction potential. Amidol is an example of the opposite and the addition of bromide, even in considerable doses, has little or no effect on the developer.

A rough idea of high, and low reduction potential, he said, may be gathered by imagining two motor cars, one of high horse-power, the other of low. Under ordinary conditions, restrained by speed limit regulations, both may travel along a flat road at the comfortable speed of 20 miles per hour (this assumption, it may be remarked, is absolutely unwarranted), but given obstacles such as a steep hill or snow on the ground, and the high-power car asserts its reserve of speed.

Lucid explanations, illustrated by diagrams, of the principles underlying development came next, followed by some remarks on the fixation and washing of negatives. The rate at which hypo diffuses out of a gelatine film, he said, is practically independent of temperature within wide limits. Given a negative film of average thickness and *effective* washing, 50 per cent. of the hypo is washed out in five minutes, and at the end of thirty minutes only 1¼ per cent. of the original concentration remains, a proportion, he regarded, as quite harmless, provided it is not accompanied by any silver compound derived from an over-used fixing bath, when the contrary prevails, and staining may ultimately result, due to sulphurisation of the compound. His remarks on washing only applied to negatives, as with prints the paper support altered the conditions. For fixing negatives he strongly advised two hypo baths used in succession, discarding the first bath when its action slowed, and employing the second in its place.

In the discussion, Mr. Luboshez said that too many photographers in their dark-room were working in the dark (no joke intended), and to such, and indeed to all, the lecture they had heard was of great value. He inquired whether the amount of alkali present in a pyro developer influenced stain? When fixing he had often noticed a reduction in the intensity of prints, and, in lesser degree, of negatives. It was easy to ruin the quality of a silver print by removing it from the hypo bath, and examining it, dripping with hypo solution.

Dr. Mees agreed: hypo solution in conjunction with air had a comparatively strong reducing action. As to pyro stain, this depended on the concentration of the sulphite, and was nearly independent of the amount of alkali present. In reply to another question, he said it was possible to remove all the silver from a yellow pyro developed negative leaving an image composed purely of stain. It had been stated such image is structureless, but this is not altogether the case, as the oxidation products, the cause of the stain, are formed round the developed silver grains, and therefore in some degree partake of their structure.

Mr. Sellors unearthed several prehistoric formulas for developers, which failed to find appreciation. On the completion of his remarks he appeared to be unfavourably impressed on ascertaining that whilst on his legs his particular potation had been inadvertently consumed by the "office boy." Mr. Raymond Crowther raised some recondite questions (not caught by the reporter hopelessly in arrear with his notes), and pointed out if an appreciable quantity of developer is carried once into the fixing bath a perceptible reduction in depth of print occurs.

Mr. Harpur assuming the deportment of a super-professor, urged all to avoid the "pitfalls of bugbears," a statement, whether applying to science, art or ragtime, hardly admitting of controversy. Unhappily descending from the general to the particular, he added that he had often noticed the partial fixation of plates in a developer containing sulphite. "I envy your powers of perception, for, to all intents and purposes, nothing of the sort occurs," said Dr. Mees. "Where argument is concerned there is a bit of the fox-terrier about me," warned the prior speaker. "I am not arguing, but merely *telling* you," placidly rejoined Dr. Mees. Mr. Harpur, with all the dignity possible under the circumstances, then resumed his seat.

Dr. Knott inquired as to the feasibility of combined development and fixing. Dr. Mees replied that this procedure involved some difficulties, for the development and fixation had different temperature coefficients. If temperatures relatively increased the speed of fixing, and the hypo got the best of things; at low temperatures development pushed ahead.

In reply to a vote of thanks proposed by the president, Mr. John Keane, in gracious and grateful terms, Dr. Mees expressed his genuine pleasure at revisiting his "spiritual home." It had trained him in the use of offensive and defensive weapons found useful on many occasions.

PARIS NOTES.

MM. J. Ducraux and P. Jeantet of the Pasteur Institute have recently published two very ingenious processes of employing ordinary commercial dry-plates for photography by extreme ultra-violet rays. A few months ago these experimenters described the construction of a simplified spectrograph for this branch of work in which they employed single quartz glasses (lenses) selected from those commonly sold for spectacles in conjunction with a water prism mounted in a metal frame having openings in it fitted with plane-parallel sheets of quartz. As regards the sensitive material it has hitherto been necessary to prepare plates specially according to the Schumann method (a description of which was published in the "B J" for 1901) in order to eliminate absorption of the ultra-violet rays by the gelatine of the emulsion. Instead of making the somewhat complicated Schumann emulsion the authors have adopted the plan of removing the bulk of the gelatine from ordinary commercial dry-plates by treatment for about four hours in a solution of 1 volume of strong sulphuric acid of 66 deg. B. in 10 parts of water at a temperature slowly falling from 85 to 70 deg. F. After removal from the acid the plates are washed in a dish in a very slow current of water, taking every precaution to avoid agitation of the liquid. After half an hour they are put to dry which they do very rapidly, owing to the very small proportion of gelatine. The exposed plates are coated with a film of collodion and when this has set, but before it has dried, the plate is immersed in water for the purpose of preserving its permeability. The authors have found that when using transparency plates treated in this manner the sensitiveness is ten times greater than plates by the Schumann process for rays of 1840 Angstrom, which is the limit of the spectrum obtainable with their water prism.

As is well known the ultra-violet may be photographed by applying a film of a fluorescent substance to the emulsion surface. MM. Ducloux and Jeantet, in seeking to find a fluorescent substance dissolving in a liquid which does not

cause swelling of the gelatine have obtained excellent results with æsculin dissolved in a machine oil and applied to the emulsion surface with cotton wool, or flowed over the latter in the form of a mixture obtained by dilution of the oil with petroleum spirit. All grease is removed from the plate before development with ether and alcohol. Plates treated in this latter way have been found to be twice the sensitiveness of those prepared by extraction of the gelatine and suffer only from the drawback that there is a slight thickening of the lines (about 1-500th of an inch) owing to irradiation in the fluorescent film. This process is applicable to panchromatic plates, in the case of which it permits of records being made throughout the entire spectrum.

Desensitising Autochrome Plates.

A good many experiments have been made, with full success, on the desensitising of Autochrome plates both with Lüppo-Cramer's phenosafranine, or the commercial varieties of it such as Ilford Desensitol or Calmel's Desensibilisateur, or with aurantia as recommended by MM. Lumière and now placed on the market, as Lumière Desensibilisateur, as a strong solution of aurantia in acetone, which is simply diluted with water to give the desensitising bath ready for use. When using aurantia one cannot employ such a measure of illumination as with safranine and the greatest care is necessary in preserving the plate from exposure to the dark room light. But, on the other hand, aurantia is better adapted to a time or factorial method of development, since the speed of the developer, both as regards the time of first appearance and the total duration of development, are not affected by this dye.

M. Ch. Adrien has recently made tests for the purpose of satisfying himself if, when treating Autochrome plates with safranine immediately after exposure, the fog and alteration of the image which generally takes place if development of these plates has been postponed, is avoided. His tests showed that there is scarcely any difference between a plate kept in the usual way and one which has been kept after desensitising. But it seems obvious that there can be no advantage in desensitising a plate shortly after exposure, when on tour for instance, if a dark-room is not available or if one does not intend to complete the development, etc., of the plate at night in an extemporised dark-room. The most advisable course is surely to desensitise at night, as can conveniently be done, and to carry out development, reversal, etc., the next morning in any room darkened simply by closing the shutters or drawing down the blinds.

One of the most accomplished workers of the Autochrome process, M. E. Ventujol, has recently modified his practice in photographing articles of artistic manufacture, many Autochrome reproductions of which by him were recently shown at a public exhibition. Almost all the negatives were made by lighting the subject with incandescent electric lamps of about 12,000 c.p. total strength. M. Ventujol used the special screen sold by MM. Lumière for Autochrome work with their "Perchlora" flash powder, and the negatives were developed with pyro in accordance with the original Autochrome instructions. In France many Autochrome workers still adhere to this developer as yielding, in their experience, the best results.

Photography of Projectiles.

At the meeting of the French Physical Society held on June 17th, M. L. Dunoyer, professor in the Institute of Theoretical and Applied Optics, made an interesting communication on the processes employed by him during the war (when he was attached to a bombing squadron) for determining, by night and by photogrammetric methods, the complete trajectory of luminous projectiles employed for the 1½ inch guns mounted on air-craft. His object was also to study irregularities of projection due to construction defects, weather conditions, and other causes. The complete trajectory was recorded simultaneously by two phototheodolites (extemporised from available materials) placed at opposite ends of a measured base and arranged with their optical axes converging in the direction of fire. A third camera was advantageously placed behind the gun, the optical axis and the line of fire being in the same vertical plane so as to record directly any error of direction. Three fixed fires were provided at known points situated in the same horizontal plane as the optical centre and were lighted on a signal being given before the firing of the gun. They provided the exact determination on each of the negatives of the principal point (foot of the perpendicular let fall from the nodal point of emergence on to the plate) and the principal distance (distance of the node of emergence from the principal point). In order to co-relate the image of each trajectory with the time factor, there was turned in front of each lens a wheel of four radii, the speed of which was regulated so that at each closing of the lens there was a gap on the recorded line corresponding to the limit of resolving power. Each of these wheels was turned at a uniform and known speed by a gravity motor, the speeds of two wheels not being necessarily the same. A simple graphic construction allowed of determining the interruptions of any one of the images relatively to the interruptions of the other and thus provided all the elements required for the graphical construction or calculation of the tragectory.

Some Novelties.

For use in conjunction with the process of combined development and fixing, recently introduced by MM. Lumière, chemicals for which have been placed on the market in carton form, there has also appeared on the market a special tank of nickelled metal, fitted with a loose rack, under the name of "Cuve Lumière et Seyewetz."

M. R. Kaufmann, an inventor whose ingenuity might well be applied to subjects of greater importance, has designed a mechanical exposure calculator. This "Posegraphe," as it is called, has certainly called for much detail work. Logarithmic scales corresponding with the chief exposure factors are arranged around a plate of about 4 x 3 inches size. On each scale is a pointer connected with the pointer moving on the scale which indicates the time of exposure. Having set each pointer in accordance with the number applying to the particular circumstances of the exposure, the pointer on the time scale automatically comes to the graduation indicating the length of exposure requiring to be given.

The growing approval with which negative paper has been received has led a maker of sensitive materials to introduce a stripping paper. MM. Bauchet and Co. have now introduced a new material known as "Isofilm B.P.A.," almost on the same lines as the Radiofilm Guilleminot previously described in these notes, consisting of a negative sensitive film temporarily attached to a card support which, in small sizes, provides a rigid surface without special precautions.

Cinematography and Taxation.

The heavy taxation levied on cinematography by the French Government (in some cases the taxes amount to 50 per cent. of the gross receipts of a cinema theatre) has had a most injurious effect upon the cinematograph industry. As an attempt to remedy this state of things while there is yet time, the Confederation des Travailleurs Intellectuels, (Association of Intellectual Workers) recently arranged a meeting in Paris to which were invited all the members of the French Chamber, many of whom were present. After some addresses, in particular by M. R. de Flers, the new member of the French Academy, and by M. L. Forest, a journalist of mordant wit who has shown a great interest in the educational and artistic aspects of the cinematograph and in its capacity to combat German propaganda, interesting demonstrations were given of the Gaumont colour cinematography and of the system of talking films emanating from the same firm. Admirable use was made of synchronised phonograph and cinematograph for the special purpose of bringing before the meeting the support of well-known political personages of the aims which prompted the holding of the meeting.

L. P. Clerc.

DEATH OF MR. S. H. FRY.

We very much regret to announce the very sudden death, on Friday last, July 8, at the age of 61, of Mr. S. H. Fry, for many years well known as the founder and proprietor of the firm of enlargers which bears his name, and until a few months ago secretary of the Professional Photographers' Association.

It was only in the early part of the present year that Mr Fry withdrew from taking an active share in his business, leaving the management of this undertaking to his son, and at the same time resigned his position as secretary of the P.P.A. He had taken up his residence at Ripley, in Surrey, in the reasonable expectation of enjoying some years of retirement and leisure. Fate has decreed otherwise, and his death, indeed, took place under particularly pathetic circumstances. Mr. Fry and his wife only the day before had entered upon the tenancy of a house in the village of Dunsfold, near Godalming. In the small hours of the next morning some cows strayed into the garden. Mr. Fry dressed himself and went down to drive them off. A few minutes later Mrs. Fry found that he had been taken seriously ill, and he died before a doctor could be brought. At an inquest held on Saturday last, it was stated that death was due to heart failure, and a verdict of death from natural causes was returned. Mr. Fry was buried at Dunsfold on Monday.

Portrait by Reginald Haines.

THE LATE MR. S. H. FRY,
Ex-Secretary, Professional Photographers' Association.

Owing to the suddenness of his decease very few of his friends had the opportunity of being present, his son and Mr. R. Child Bayley, a close friend, being the only mourners. A wreath was sent by the Council of the Professional Photographers' Association, and at the council meeting of the Royal Photographic Society on Monday last a message of condolence with Mrs. Fry was ordered to be sent on behalf of the Society, of which Mr. Fry was a life member.

Mr. Fry was the son of Samuel Fry, formerly a photographer of Kingston-on-Thames, who in the early days of the gelatine emulsion process commenced the manufacture of dry-plates which were of a greater rapidity than those then on the market, due to the method of preparing the emulsion worked out by Charles Bennett, a well-known amateur experimenter. These plates were placed upon the market as the "Kingston," and for some years occupied a leading place among similar products, as did also other manufactures of the firm, such as bromide paper. It thus came about that Mr Fry, in his early days, acquired a practical knowledge of emulsion making and subsequently of the making of enlargements whilst employed in his father's business. Following engagements with one or two firms of photographic manufacturers, he established the business of trade enlarging, which has steadily grown in importance. He was one of the first to embark in the business of developing and printing amateurs' film exposures, at a time when few commercial firms perceived the large amount of profit to be won from this branch of work.

Continuously with these business occupations, Mr. Fry was a prominent participant in photographic society meetings. Until a few years ago he took a considerable interest in the Royal Photographic Society, but was perhaps most regularly present at the meetings of the London and Provincial Photographic Association and the now extinct Photographic Club. But his connection with photographic society life was closest in the case of the Professional Photographers' Association, of which he was an original member and upon the Council of which he had served for many years, and in which body's affairs, first as honorary and subsequently as paid secretary, he had taken a prominent share of management.

Possessed of a mordant and somewhat cynical wit, Mr. Fry's outward personality perhaps belied the seriousness with which he applied himself to any matter in which he had assumed responsibility. Whilst applying a naturally shrewd judgment to any subject under discussion, it was impossible for him to deny himself opportunities for wit or satire. Perhaps on this account he was sometimes misunderstood by those of less lively habit of mind, but he lightened many a technical or business conference, where, however, he was loth to speak except from first-hand knowledge.

Sympathy will be extended to his widow and to his son, Mr. A. B. Fry, who for some considerable time past has been in sole control of the business of S. H. Fry, and will continue to be responsible for its direction.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

Applications June 27 to July 2:—

CAMERAS.—No. 17,947. Photographic cameras. F. Bradley.

STORING PHOTOGRAPHS.—No. 18,036. Devices for storing and displaying photographs. F. J. Phillips.

FILM DEVICE.—No. 17,915. Roll film turning device. K. Sayo.

DAYLIGHT DEVELOPMENT.—No. 17,432. Apparatus for daylight developing photographic roll films. J. Welch.

APPARATUS.—No. 17,932. Photographic apparatus. W. Fenerzeng.

PRESS ILLUSTRATIONS.—No. 17,706. Transmission and reproduction of press illustrations. M. L. D. McFarlane.

CINEMATOGRAPHY.—No. 17,674. Means of daylight projection of animated pictures. T. F. Newman and A. F. Scott.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in each case is that of application in this country; or abroad, in the case of patents granted under the International Convention.

OPTICAL PROJECTION.—No. 160,492 (November 19, 1919). In order to produce a uniform illumination from a filament lamp or like banded source of light, the condenser is so formed that the field of illumination produced by the converging rays projected thereby from each point of the source gradually increases in intensity towards the centre, as by giving the condenser negative spherical aberration, the fields so formed overlapping to produce a uniform field. As shown in Fig. 1, the condenser C may be of the Fresnel type having a central "bulls-eye" c^1 and outer ridged zones c^2, c^3, c^4, c^5; the foci of the several parts of the condenser are located beyond the film or slide D to be projected, and the outer zones focus the rays at greater distances beyond the picture plane than the inner zones, but at less distances than the "bulls-eye." In a modification, the condenser consists of a lens having a non-spherical convex surface. The negative Fresnel lens may be combined with an ordinary positive lens, such as a plano-convex lens M, Fig. 2. One of the lenses may be provided with a series of diffusing-flutes c^6 parallel to the bands of the light source. A method of determining the proper position of the light source is

described, in which an image of the filaments is focussed on a special screen, which may consist of the shutter of the projector. In this operation, the fluted lens C', Fig. 2, is turned through a

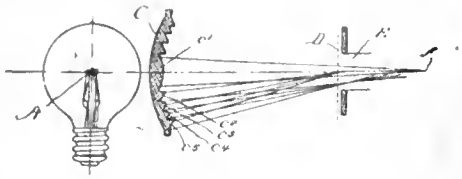

Fig. 1.

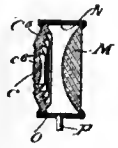

Fig. 2.

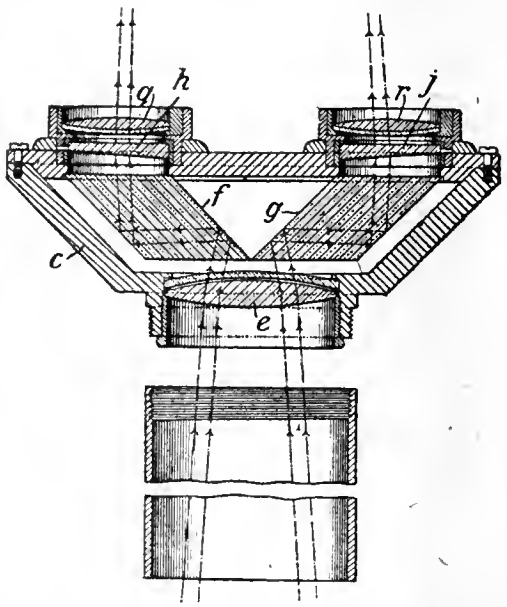
right-angle. Optical data for the various forms are given by means of diagrams.—A. J. H. Haddan, 31, Bedford Street, Strand, Westminster, for Corning Glass Works, Walnut Street, Corning, New York, U.S.A.

Stereo-Cinematography.—No. 160,512 (December 16, 1919). The invention comprises a prismatic optical system for use as a projector for the pictures of a cinematograph apparatus, in which two images of a single picture are simultaneously thrown on to the screen and superimposed. In place of the usual projecting-lens a system is used consisting of the back component *e* of an ordinary lens, in front of which is mounted two rhomboidal



prisms *f*, *g*, each reflecting half the rays through lenses *q*, *r*. To ensure correct superimposition on the screen, wedge-prisms *h*, *j* are fitted, and are capable of rotation. The lenses *q*, *r* are mounted in eccentric cells to facilitate adjustment. The whole system is mounted in a casing, *c*, so that it may replace any ordinary projection lens.—Charles Henry Frampton, 209, Balham High Road, London, S.W.17.

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

New Apparatus.

Razor Blade Print Trimmer.—Messrs. Butcher & Sons, Camera House, Farringdon Avenue, London, E.C.4, have given practical shape to the suggestion often made that one should use old safety razor blades as print trimmers. They now supply a stout metal handle which allows of a used Gillette razor blade being

quickly and most firmly inserted. We have found that the device is an excellent knife for trimming prints and undoubtedly will find favour with those who have a supply of the Gillette blades. The price is 3s. 6d., and the appliance is already in stock with most photographic dealers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sunday, July 17.

Hammersmith (Hampshire House) P.S. Outing to Wisley.

Monday, July 18.

South London P.S. "Platinotype." W. H. Howard.

Wednesday, July 20.

Bradford Phot Soc. Evening Excursion to Cottingley and Beckfoot.

Thursday, July 21.

Hammersmith (Hampshire House) P.S. "Cameras." Miss Chatterton.

Saturday, July 23.

City of London and Cripplegate P.S. Outing to the Zoo.

Manchester Amateur Phot. Soc. Ramble from Wilmslow to Prestbury.

Commercial & Legal Intelligence.

Legal Notices.—Notice is given of the dissolution, by mutual consent, of the partnership between Lucy Arnold and Henry Alfred Sutch, carrying on business as fine art restorers, at 47, Beauchamp Place, Brompton Road, S.W., under the style of Arnold and Sutch.

NEW COMPANIES.

Sanders, Austin and Co., Ltd.—This private company was registered on July 2 with a capital of £1,000 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in apparatus and appliances for making, presenting, or reproducing photographic or other pictures, and any electrical, optical or other apparatus, etc. The permanent directors are: T. Sanders, 27, Fields Park Road, Cardiff; I. T. Austin, 134, King's Road, Cardiff. Qualification (except first directors), £100. Secretary: I. T. Austin. Registered office: 50, Charles Street, Cardiff.

Imprensa, Ltd.—This private company was registered on June 29 with a capital of £5,000 in £1 shares. Objects: To carry on the business of lithographers, engravers, colour-process and half-tone engravers, stereotypers, photographers, etc. The permanent directors are: A. H. Burton, 22, Aubrey House, Maida Hill, West, W.2, physician; E. R. Holden Quinta de Almaraz, Almada, Portugal, cork merchant. Qualification of permanent directors, 2,000 shares of ordinary; of ordinary directors, 500 shares. Solicitor: G. A. Morgan, 1, Woodbury Lane, Clifton, Bristol.

Jonathan Fallowfield, Ltd.—This private company was registered on July 1 with a capital of £20,000 in £1 shares (12,000 8 per cent. preference). Objects: To take over the business of a wholesale and retail photographic dealer carried on by J. Fallowfield,

of 146, Charing Cross Road, W.C. The first directors are: F. W. Hindley, Tonlegee, Bushey, Herts.; F. D. Hindley, High Prestwick, Haselmere, Surrey; H. J. Traise, 40, Cedar Road, Cricklewood, N.W. The two first-named are permanent. Qualification, £200. Remuneration as fixed by the company. Registered office: 146, Charing Cross Road, W.C.

Colour Cinematography Syndicate, Ltd., has been registered, with a nominal capital of £40,000 in 35,000 preferred ordinary shares of £1 each and 100,000 ordinary shares of 1s. each, to acquire the patents and inventions of Professor S. M. de Procoudine Gorsky relating to a process for taking and developing still photographs, transparent slides, and cinematograph films in natural colours, etc.

The first directors are: Prof. S. M. de P. Gorsky, The Dell, Croft Road, Sutton; D. N. Dunlop, A.I.E.E., 36 and 38, Kingsway; G. Smith Orr, J.P., Glasgow; R. G. Booth, 9, Landrock Road, Crouch End; J. MacAlister, Glasgow; J. M. Preston, Glencraig, Fife; G. C. Möller, Drammen, Norway.

Minimum cash subscription, £7 Director's qualification, 100 shares. Remuneration, £250 each per annum, free of income tax.

Wiggins, Teape and Co. (Export), Ltd.—This private company was registered on June 29 with a capital of £1,000 in £1 shares. Objects: To carry on the business of wholesale, export, and manufacturing manufactnrers of photographic, artistic, or other articles, etc. The first directors are: P. W. Wood, Queen Anne's Mansions, S.W.1; A. E. Parke, Edgehill, Wadhurst, Sussex; F. L. T. Barlow, Eythorne House, Eythorne, near Dover; K. Barlow, 3, Vicarage Gate, Campden Hill, W.8; T. L. Parke, Withnall Fold, near Chorley, Lancs.; L. W. Farrow, 10, Brookview Road, Streatham, S.W.10; W. G. Hay, 19, Marine Parade, Brighton; J. Horsburgh, "Strathculm," Hele, near Cullompton, Devon; J. P. Hepburn, The Red House, Hele, near Cullompton, Devon; all directors of Wiggins, Teape and Company (1919), Ltd. Solicitors: Pleese and Sons, 15, Old Jewry Chambers, E.C.2.

News and Notes.

Mr. G. I. Higson, M.Sc., of the British Photographic Research Association, hitherto A.I.C., has been elected a Fellow of the Institute of Chemistry.

Glut of Photographers.—A Sunday newspaper states that hawkers and itinerant photographers are so numerous at Cheddar Gorge that the authorities have had to appeal to the police.

The Holiday Friend.—Messrs. W. Butcher & Sons, Camera House, Farringdon Avenue, London, E.C.4, have just issued for the holiday season an attractive folder leaflet, entitled "Who is your best holiday friend?" This is for the use of dealers, to whom copies can be supplied, with a dealer's own imprint, at 20s. per thousand.

A Flashlight Hint.—A correspondent, who is of opinion that there is nothing to beat fusees for firing flashlight compounds, states that these useful accessories are again on the market, and are being sold in London streets by hawkers, if not in the shops. Once upon a time there was a fusee magnesium lamp on the market, but fusees disappeared some years before the war.

Ex-Enemy Debts.—The Board of Trade announce that by an agreement made with the German Clearing Office now awaiting the approval of the Reichstag, the time for lodging claims with the British and German Clearing Offices by their respective nationals under Article 296, Section III. Part X. of the Treaty of Versailles has been extended to September 30, 1921. No further claims under the above Article will be accepted after that date by the Clearing Offices concerned.

Camouflaged Photographers.—One of the most conservative institutions in the world, Lloyd's, was photographed more or less secretly last week. To get a truthful representation of the scene in the underwriting room, it was decided by those in authority that the intention to photograph the scene should be kept secret, and one day last week members in transacting business took little notice of some painters who with ladders and other things seemed busy high up on the walls. The "painters," the daily papers tell us, were really camera men in disguise.

The Annual Outing provided by Messrs. Wellington and Ward for their employees took place on Saturday last, when a party numbering over 300 visited Brighton by motor chars-à-bancs. After spending the greater part of the day in Brighton and thoroughly enjoying the bathing and numerous other items of interest which that popular resort has to offer, the return journey, also by road, was made to Elstree, with the usual one or two stoppages for light refreshments en route. Absolutely perfect weather conditions prevailed, and the trip throughout was most enjoyable. The firm provided a private car fully equipped with Red Cross and first-aid appliances, but fortunately they were not required, as, in spite of the great heat, no casualties were reported—a fitting tribute to the "keeping qualities" of the firm's employees!

Miniatures and Woodcuts.—A little exhibition of ivory miniatures, held by Madame Yevonde at her studio, 92, Victoria Street, London, S.W.1, contained some very beautiful examples, the majority on a photographic basis. Among them was a striking portrait of Lord Reading, from the negative made by Madame Yevonde shortly before the Viceroy's departure for India. But most were of women, who form the greater part of Madame Yevonde's sitters, and who provide the miniature painter with the most suitable subjects. A collection of portrait woodcuts by Miss Dorothy Mullock, shown at the same time, provided some interesting examples of the broad effects to be obtained in this method of engraving. Miss Mullock's impressions from the blocks were pulled in monochrome and very effectively coloured in water colour. Their novelty, as a form of portrait, suggested the possibility of providing the requisite drawing on the wood block by photographic means and applying the art of the photographic colourist to the treatment of the impressions. Wood engravers, no doubt, would exclaim against such a programme, but for certain subjects and styles of lighting there would seem to be possibilities in it.

Ross Advertising.—Messrs. Ross, Ltd., Clapham Common, London, S.W., send us a complete selection of the advertising literature, etc., prepared by them for the use of dealers. In addition to the full price list of Ross lenses and cameras, there is a smaller, but very fully illustrated, list of lenses. This 24-page publication contains many reproductions of work done with Ross lenses and also a set of drawings illustrating the optical and mechanical processes in lens making. As regards show cards and window bills, Messrs. Ross have brought together an imposing series in which actual photographic prints of sporting subjects, landscapes, portraits, etc., are used for the joint purpose of offering an attractive picture and at the same time of displaying the photographic excellence of a Ross lens. These showcards are supplemented by two reproductions in colours of artists' drawings, which further emphasise the close connection between photography of sporting events and the use of a Ross lens. Messrs. Ross have evidently given so much consideration to the production of striking sales making showcards that dealers certainly cannot do less than apply for examples and give them a prominent display in their windows.

Dr. Mees at the Polytechnic.—On Wednesday, July 6, Dr. C. K. Mees addressed the students of the Photographic School at the Regent Street Polytechnic, his subject being photographic chemistry. After a brief reference to the early use of chloride of silver, which he took as a type of light-sensitive salt, he demonstrated the making of a bromide emulsion. A particularly interesting section of the lecture was devoted to the properties and behaviour of gelatine, the phenomena of shrinkage, reticulation, and the structure of the emulsion film being shown upon the screen. The various types of developer, such as pyro hydrokinone, metol and amidol, were described, and their specific qualities demonstrated by lantern slides of graduated exposures. The necessity for thorough fixing and washing was emphasised by the lecturer.

In proposing a vote of thanks to the lecturer, Major Warwick, Assistant Director of Education, Polytechnic, congratulated the students on their good fortune in obtaining such an instructive lecture from Dr. Mees during the few days which he was spending in England. Dr. Frederick Rose, M.A., of the Education Committee, L.C.C., who was visiting the school, remained during the whole lecture, and at its conclusion said that such knowledge as

Dr. Mees had imparted was of the greatest value to the nation. It was formerly an article of faith with the British nation that "trade followed the flag," but it was no longer safe to trust to this idea, as it was becoming more and more evident that the world's trade would be captured by those nations who applied the most scientific methods to the production of their goods. He urged the students to devote their energies to mastering the theories underlying their practical work, and where possible to endeavour to add to existing knowledge by original research. In acknowledging the vote of thanks, Dr. Mees said that the backbone of our great industries was composed of men of great technical ability with sufficient scientific training to form an effective link between the research worker and the workshop or factory. Another great factor in commercial success was to be found in the personality of the man at the head of affairs. He gave an instance in which all the most valued experts of a firm deserted it to found a rival concern, but without doing it any material damage, while the new business soon came to grief for lack of the necessary directing energy and acumen.

STEREOSCOPIC PHOTOGRAPHY OF SMALL OBJECTS.

To the Editors.

Gentlemen,—I think Mr. Bedford will find that the all-important essential in this question is the suitable focus of stereoscope used for viewing the slide. I have a stereoscope, for instance, of 3¾ in. focus, which makes absolute nonsense of his three examples; that is, it minimises the relief and exaggerates the size of the cube, throwing it all out of drawing. The three examples of different camera lens separation each calls for its own particular focus of stereoscope, and with the ⅝ in. separation slide, if a long focus stereoscope be used to get the proper amount of relief, the apparent natural size of object is sacrificed and vice versa.

My stereoscopic creed is that for natural effect the camera lens separation should be the normal eye separation, 65 m.m. (2.56 in.), and that the stereoscope lenses must be of such focus as to give the same apparent or angular size as given by the actual object in Nature. With 3½-in. camera focus lenses I find that 3¾-in. to 4-in. focus lenses in the stereoscope give the desired result, for *ordinary* views. Oliver Wendell Holmes, in "The Poet at the Breakfast Table," gives an easy method of making this test. After saying that the object in the stereoscope is the same size as the object in Nature, he offers to bet on it, and makes the doubter look with the right eye at the stereo. transparency slide in the stereoscope; whilst at the same time looking with his left eye at the actual view, and either by sliding one view over the other, or by ranging the two views alongside each other, convince himself that image and object are the same apparent size. The test must, of course, be made from the same standpoint as the camera.

In coming to objects at very close quarters, the eyes are slightly converged, and the 2½-in. camera lens separation theoretically calls for a corresponding reduction. But I have taken small objects, half-size at 10½ in. away from lens with the 2½ in. separation without the effect of exaggerated relief. But the 3½-in. focus is no longer suitable for such slides. At 10½ in. away from the object the lens is racked out to 5¼ in. instead of 3½ in. from the plate, and a corresponding longer focus stereoscope must be used.

I should be very glad if Mr. T. J. Ward would give us the methods he refers to for determining the proper focus of lenses to use in the stereoscope, giving the focus of camera lenses and the other conditions such as occur in the photography of small objects at close range. The point is one of some scientific interest. For instance, in the photography of small natural history specimens to half, or full size, the use of the correct lenses in the stereoscope is essential if the effect of both natural size and natural relief is to be obtained.—Yours truly,

R. W. Blakeley,

4, Seedley Park Road,
Near Manchester,
July 7.

THE BETTER SIDE OF THE FACE.

To the Editors.

Gentlemen,—The issue of the "B.J." dated April 29 has only just reached me here, and I have read with the greatest interest Madame Yevonde's lecture, in which she states that "in 99 cases out of a 100 the left side (of the face) is the more beautiful, owing to the fact that careful mothers, when we are babies, put us to sleep on the right side, and the bones of the face being soft and unformed, suffer accordingly."

It is interesting to know what you on your side believe to be the cause of one side of the face not being so well formed as the other side, but I would like to point out that we Americans believe something else to be the cause.

The matter attracted the attention of some of our leading men in the winter of 1889, when Sarony, of New York, attributed the cause to the habit of sucking the thumb. His dictum, and the one generally agreed upon, was that when baby's chubby little thumb is in his (or her) mouth, the forefinger presses the cartilages of the nose on one side, and by degrees completely out of shape. Sarony gave some interesting experiences in support of his statement, but I need not trouble you with them. All I need say in conclusion is that those mothers who stop thumb-sucking during childhood are likely to have the best-looking children.—Yours faithfully.

W. G. Taylor.

Washington, U.S.A.

HYPO IN THE DEVELOPER: SOME NOTES ON COMBINED DEVELOPING AND FIXING.

To the Editors.

Gentlemen,—Many of us have no doubt at one time or another tried one or more of the many methods of combined developing and fixing, with more or less—usually less—success, believing there to be something in the process. Formulæ have been many, and advocates, as well as compounders of the same, have done their best to make such solutions popular, but, so far, their efforts have been in vain. To-day, however, the method is nearer to perfection than it has ever been, and well worth the further attention of experimentalists.

Pyrocatechin was, I believe, first used for the work (in 1898), and the late Mr. J. McIntosh—an indefatigable user and advocate of the method—decided in favour of Kachin, which, later on, was found to be pyrocatechin, or as near like it as made no difference. I was witness to some of Mr. McIntosh's experiments, and some of the excellent negatives produced, though I failed most miserably with Kachin, my best results being obtained (in 1912) with the amidol-hypo formula advocated by M. Cremier. I also tried edinol, metol-hydroquinone, and ortol with hypo, but with little success, and I came to the conclusion that amidol and pyrocatechin—particularly Dr. Elion's formula for the latter—were the most suitable agents if a really reliable method of mixing hypo with them could be found.

The chief drawback to the process of combined developing and fixing has been the absolutely necessary correct adjustment of the developing agent and the hypo, for, obviously, if the hypo is in excess the plate becomes fixed before development can be completed, whereas if the developing agent predominates the negative becomes over-developed before it is fixed, making in the latter case—if one has an eye on proper density—a separate fixing bath necessary if the negative is to be rescued, thus doing away with the great advantage and main object of the process, namely, developing and fixing in one solution.

A properly constituted solution is one in which the developing and fixing agents must work in greater harmony than, say, a

Government, and together must run unitedly in double ... and so finish in what may be described as a dead heat ... a consummation devoutly to be wish'd." Chemicals of ... and even quality, particularly hypo, and the most accurate ... compounding of the same are therefore as important ... good formula. Indeed, I believe that all the formulæ I have ... are good, and that perfect results are possible under favourable ... conditions, non-success with them being due to improper ... or using, if not impure, chemicals. Thus when using hypo ... developer it is advisable to ... and rub dry the crystals ... weighing them, washed ... washed crystals giving in ... hands quite different results ... do the pure crystals and ... orthodox variety, the latter ... about half the price of the ... ner. Much depends upon ... and compounders of ... who should be most explicit ... using it, that is, using hypo ... hypo.

The above remarks are suggested ... our Paris ... (p. ... 389), in which it is stated ... another ... useful attempt has been ... Continental ... for ... fully satisfactory method of ... developing ... I am sorry your Parisian ... correspondent does not ... us of it, particularly some information concerning ... structure, two very important factors about which M. Cle... ...gely reticent. We who care to experiment with the ... advocated can, of course, solve these problems for ourselves, ... it would have been better and to our great advantage had ... been explained.

There are many submerged rocks in this branch of work, ... ry and practice do not appear to work in agreement. It might ... thought, for instance, that developers having a high factor ... would be the most suitable agents to work first with hypo, ... such is not the case. One's first idea, naturally, is to secure ... image, no matter how weak, at the earliest possible moment, ... may do with a high factor developer, and then to strengthen ... ere the hypo has a chance to overbalance and perhaps destroy ... of the latent part of it, but this plan does not appear to ... the manner expected of it. Experience teaches us that developing ... ving medium (factor, number, pyrocatechin, Kachin, amidol, ... etol-hydroquinone, potassium ... and the most satisfactory ... ming between the pouring on of the developer and the ... ce of the image allowing the hypo to start its work. This ... other form of chemical handicapping appears to be ... M. Bunel seems to have discovered it in acetone. ... Another curious and seeming contradictory point is that with ... ment of combined developing ... doing a very fully ... ...n is necessary, because of ... something like two ... ...ishing the exposure. ... impossible to get ... ...ish unless one gives ... ...ish beyond the ... ...d yet a generation ... ... we were advised to add ... ...ypo to a developer ... under-exposure, in order ... ...get the most from ... ... But more of this ... ...ding we process, in which I ... particularly interested. ... M. Bunel has, I believe, ... secret of success in ... ...ns as a constituent of ... developer and fixer. ... ...long been considered a ... addition to certain developers, ... I have never before heard ... being combined with ... developing agent and hypo. ... ...ecise action of acetone ... developer under these ... ...y be unable to say, but I ... ...dabbler in chemistry, know ... ...hen mixed with ... ...forms acetone sulphite, and ... ...of the sulphite combines ... the developing agent to form ... ...compounds, so that it may ... ...d to play of sulphite when ... ...is present, hence the ... ...pyro-acetone developer. Pyro, 60 grs.; acetone sulphite, 560 grs.; acetone, 12 minims; water to 10 ozs. ... M. Bunel's formula acetone appears to have a balancing ... ...ping action, causing the developing and fixing agents ... with greater harmony than they hitherto have done, and ... in some mysterious way, the too rapid advance of ... ...amidol) or the hypo should one have a ... ...its work before the other. This check, which may ... to be automatic, has long been wanted, and it appears to ... found in acetone.

... with the developer-fixer advocated in your ... ...more promising than those carried out some ... ...formula, but I have for the moment suspended ... further operations, ... learn from ... experimen... ...by ... ...olution ... ...closely related ... ...normal develope... ...It's use in ... ...ing that plate ... ...or an ... ...Thomas Woods.

... ...ulty. ... ...Council ... There ... P.P. ... ...photo... ...yself to ...

We offer our united sympathy to his widow and son. May they reap some comfort from the knowledge that their dear one will be mourned and affectionately remembered (not only by his fellow Councillors, but by the members generally) as a devoted pioneer of the P.P.A. right to the end.

"Requiescat in pace."

Yours faithfully,

LANG SIMS,
Secretary, P.P.A.

TO SAVE A PLATE.

To the Editors.

Gentlemen,—The following "wrinkle," though probably familiar to most of your readers, may be new and useful to some. If a plate when placed in developing dish proves to have been unexposed, at once rinse in clean water, drain for a few seconds, reinsert in dark-slide and promptly expose on any available subject. Image will already be visible on removal, and re-immersion in developer will produce a negative indistinguishable from those by ordinary treatment.—Yours faithfully, EUSTACE J. EASTMAN.

The Avon Studio,
West Moors, Dorset.
July 11, 1921.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

O. M. T.—There can be little doubt that the stains are due to imperfect fixation. As a rule, film development and fixing are rather "rushed," and traces of silver left in the film become evident on intensification.

H. D.—It is a little difficult to advise without seeing specimens. You appear to be over-developing, the pyro-soda increasing the defect. The defect seems to be still further increased by using S.C.P. paper. In other words the pyro-soda developer and the paper tend to increase contrasts. The plate used is a very good one, and we would suggest a trial being made with a softer developer—"Azol" for example, or, of course, less development with the pyro-soda. We presume you are exposing correctly; if you are not doing so it is probable that under-exposure is the cause of all your trouble.

H. E.—Technically your two prints are very good, the colour of the toned one is a trifle too warm for our liking, but many like it, and it is looked upon as being a good saleable colour. Pictorially we should say there are too many blossoms; they give a speckled effect to the picture, which detracts from the model. More of the lady's left arm, also the hand, should have been shown—or none at all. As it is now it appears disjointed and incomplete because of the mass of foliage. The use of an even larger stop would have separated the model and the near foliage (that in the same plane as the head) from the distance, and would have given a better effect. On the whole, however, the results are good and above the average of outdoor figure work.

H. T.—It is perfectly well established as a custom of the photographic trade that the negative is the property of the photographer, to be used by him in accordance with the customer's order, but, in the absence of special contract in the first instance or subsequent contract, not the property of the customer. This custom has been confirmed in the Courts on several occasions, and particularly in the case of the Rotary Photographic Co. *v.* Taber Bas Relief Co. in the High Court in 1903. In this case the negatives were specially charged for, yet it was held that they were the property of the photographic firm. In the little volume, "Photographic Copyright," which we issue, you will find a chapter on this question of the ownership of negatives in which an abstract is given of this decisive judgment.

A. W.—(1) The one-solution mixture will require a little potassium bromide if used for gaslight prints. We strongly advise you, however, to use the M.Q. developer recommended by the maker of the gaslight paper you use, as by so doing your prints would be of a better colour, it being a difficult matter to find a developer that will give the best results on all papers. (2) As a rough guess we should say a 6-inch focus lens was used with a rather small stop—certainly not larger than *f*/16. It is, however, very difficult to say. (3) Shutting the lens down more will not increase the area of illumination. If the picture is cut off with open aperture, it will remain cut off, no matter how small the stop used. (4) Special washers are made by Kodak, Houghtons and others, and you cannot do better than write to one or the other for particulars.

T. B. S.—We have met with no difficulties with the toner you are using for toning bromide prints to a Bartolozzi red, but as an alternative method you might try that advocated by Mr. C. W. Somerville, in his book, "Toning Bromides":—Make a saturated solution of ammonium carbonate by adding 3 ozs. of the crushed salt to 10 ozs. of cold water, allowing it to stand two or three days, shaking as often as possible. Make up the following solution in order given:—

Ammonium carbonate (sat. sol.)	1 oz.
Copper sulphate	10 grs.
Potassium ferricyanide	25 ,,

Any precipitate which forms when the copper is added to the ammonium carbonate will be re-dissolved. The solution should be perfectly clear, but should be used immediately, as a precipitation is likely to occur after long standing, especially if the solution has been used. If much work is going to be done with this toner it is advisable to keep a fairly large stock of ammonium carbonate by putting an excess of the salt in a bottle and keeping it covered with water and well stoppered. Toning should be continued until the deepest shadow is converted and allowed a minute longer. The print may then be washed for 10 minutes. Preferably it should be immersed in the acid hypo bath to remove any unconverted silver salt and again washed. Should there be a pink stain in the whites of the print it may be easily removed by treating with a 1 per cent. solution of ammonia. If the ammonia be too strong it will destroy the colour.

JOURNAL OF PHOTOGRAPHY.

No. 3194. Vol. LXVIII. FRIDAY, JULY 22, 1921. Price Fourpence.

Contents.

SUMMARY.

In the current chapters of his articles on photography for the newspapers, Mr. W. Lancelot Vining deals with the advantages of flashlight as an auxiliary in press photography, and has some hints to give on the making of portraits for reproduction in newspapers (P. 427.)

In a contributed article, Mr. Arthur G. Willis deals with some of the advantages of the Carbro process (of making carbon prints from bromides), particularly from the standpoint of the professional portraitist. (P. 434.)

Some notes on the use of panchromatic plates, by Mr. H. N. Holland, deal with a number of practical points, and refer to the advantages of these plates in outdoor work. (P. 429.)

A recent paper by M. G. Cromer, before the French Photographic Society, has described methods for the use of large-aperture lenses in portraiture in order to simulate the effect of binocular vision (P. 430.)

In a leading article we refer to the advantages of orthochromatic plates for portraiture by both daylight and artificial light. Although their merits may not be capable of such striking display as in the case of more highly coloured subjects, they are nevertheless positive enough to justify the adoption of the orthochromatic plate in regular work. (P. 426.)

The Revd. H. C. Browne, M.A., in a paper on lens separation in the stereoscopic photography of near objects examines the question as regards the viewing of the positives, as well as regards the taking of the negatives. (P. 432.)

On the proposition of Dr. Rodman, president of the Royal Photographic Society, donations are invited for a permanent memorial to William Henry Fox Talbot (1800-1877), from whose researches present-day photographic and photo-mechanical processes originated. (P. 439.)

We regret to record the death of the eminent French physicist, M. Lippmann, whose "interference" process of colour photography raised great hopes thirty years ago. (P. 435.)

A recently patented invention in aerial photography consists of a supplementary camera in which the compass bearings at the moment of exposure are photographed. (P. 436.)

The working of ordinary P.O.P. removal of ink stains from negatives and prints, and extemporising of a focussing screen are the subject of "Assistants' Notes." (P. 435.)

In making reproduced negatives on glass plates, want of contact between the two plates may easily give rise to imperfect definition if the ordinary pattern of printing frame is employed (P. 426.)

Considerably longer life of the inexpensive unmounted gelatine light-filters is obtained by a simple form of mounting between a pair of rings of thin card, cut to size for insertion in the lens tube. (P. 426.)

EX CATHEDRA.

A Fox Talbot Memorial. As will be seen from the letter in another column from Dr. G. H. Rodman, the Royal Photographic is moving to create a memorial to William Henry Fox Talbot, to whose investigations the methods both of photography and photo-mechanical reproduction, as we know them to-day, chiefly owe their origination. It is a laudable object, and one which has been too long delayed. In France the scientific inventor, even if he does not fare better than elsewhere during his life-time, is assured of an adequate posthumous tribute. At Chalon and Bry, respectively the homes of Niepce and Daguerre, the work of these pioneers is commemorated. Only a few months ago, in Paris, on the site of Daguerre's Diorama premises being identified, permission was obtained to perpetuate the fact by the erection of a mural tablet. Fox Talbot, to say the least, is deserving of an equivalent measure of public testimony to the value of his labours on the part of the present generation, and it is to be hoped that the appeal of the Royal Photographic Society will meet with a wide response. It is proposed that the memorial should be established at the village of Lacock, the home of Fox Talbot and his forebears for a great number of years, and the place which is intimately linked with the genesis of photographic processes.

* * * *

Mounting Gelatine Filters. Many photographers using colour filters for ortho or panchromatic plates for reasons of economy use the gelatine film slipped between the components of the lens. This plan is in every way satisfactory, the only argument against it being that the gelatine surface of such filters is very delicate and easily spoilt through over much handling. It is a good plan when purchasing these filters to mount them for use between two circular-shaped rings of thin cardboard of exactly the diameter of the lens. This will enable the filter to be handled without the fingers actually coming into contact with the gelatine film, and will further assist in removing the filter from the lens. Care must be taken that the inner circles of the mounts are no smaller than the largest stop fitted to the lens, or exposure calculations will be seriously upset. If there is a difficulty in slipping the mounted filter out of the lens a couple of tiny tabs of black velvet may be attached to the edge of the cardboard mount. These will allow more easy handling if the lens mount is too deep or narrow to allow the insertion of the fingers, and if the filter mount is a tight fit (which it should be in order to keep it central and avoid interference with the stop) a pair of small tweezers may be employed to grip the tabs and lift the filter out. The above plan is of real value in keeping the gelatine filter in good condi-

tion, and the trouble is well worth while in saving the cost of the constant renewal of spoilt filters, due to the accidental touching of the gelatine surface.

* * *

Unmounted Prints. A problem which often faces the photographer is to find a means for preventing unmounted prints upon emulsion-coated papers, either gelatine or collodion, from curling. In the early days of bromide papers it was a common practice to immerse the fixed and washed prints in a weak bath of glycerine and water. This, of course, prevented them from becoming "bone dry," but experience proved that it was conducive to rapid fading, and it is now seldom done. A better plan, based upon the experience of cardboard manufacturers, is to keep the prints flat while drying, applying moderate pressure until all moisture has departed. Prints so treated will remain flat, unless they are allowed to become very damp and dry again in the open. In the case of collodion emulsion papers, the prints may be taken directly out of the water, the surface moisture blotted off, and then transferred at once to a dry blotting book. Gelatine papers are best treated with a weak formaline bath, hung up to become surface-dry, and transferred to the blotting book as soon as the surface is hard enough. It is desirable that the special "fluffless" paper sold for the purpose is used. A slab of plate glass on top of the blotting board will provide sufficient pressure.

* * *

Temperature and Development. In spite of all that has been written and said upon the subject, many photographers have lately been getting negatives which are much too thick for their liking. The brilliant light we are experiencing has ensured full exposure, and the high temperature has hastened development. To secure satisfactory negatives in these conditions, one of two things may be done. The developer may be cooled by the use of ice, or it may be diluted so as to bring its working time back to the normal. It should be remembered that different developers are differently affected by temperature, pyro-soda perhaps the least, and hydroquinone the most. Some may think to meet the case by using bromide of potassium as a restrainer, but this affects the scale of the negative, and, while it prevents a thick, clogged-up appearance, it is likely to produce hardness. It is, of course, desirable to keep the dark room as cool as possible, and if it can be arranged to avoid developing during the hottest period of the day, so much the better.

* * *

Reproduced Negatives. An often unsuspected cause of inferior definition in negatives which have been reproduced by contact from a transparency is to be found in the want of uniform contact between the original negative and the transparency plate, and subsequently between the transparency and the plate which is to yield the final negative. This was impressed upon us recently when making a number of transparencies from a very fine line negative. Under a magnifier the lines in these were distinctly unsharp, and it was only when a process printing frame with powerful screws was used that satisfactory results were obtained. The reason for this is simple. Sheet glass as used for modern plates is more or less curved, and the emulsion is coated upon the concave side, so that, with a weak spring pressure in the printing frame, the centres never come into contact. Failing such a printing frame as we have mentioned, it is better to make both transparency and negative in the camera, when with careful focussing and a moderately small diaphragm the difficulty will not arise. Another way to secure sharpness is to make the exposure at a considerable distance from a small source of light, and to keep the frame perfectly still the whole time.

ORTHOCHROMATIC PLATES IN PORTRAITURE.

Although practically every intelligent photographer uses authochromatic—or, as they are indifferently called, isochromatic—plates for certain classes of work, we believe that comparatively few appreciate to the full the advantage of employing them for the ordinary run of studio portraiture. Possibly this is due, in some measure, to the methods which have been adopted by writers and demonstrators to prove their particular qualities. For example, a bunch of marigolds and cornflowers makes an excellent test-object, the ordinary plate rendering the yellow flowers as if dark in colour, and the deep blue ones as if nearly white, while upon the ortho' plate these tones are reversed, giving very nearly the actual visual effect. When a similar comparative test is applied to an ordinary sitter, the two negatives do not show this striking difference, especially if no colour filter, or what is popularly known as an iso-screen, has been used, and consequently the advantage of using them has been questioned, and the "ordinary" plate has held the field.

In case there may be any misapprehension in the matter, it may be well to state that for any normal subject there is not the slightest disadvantage in using ortho' plates to the entire exclusion of ordinary ones, and, as the cost of the two kinds is the same, no economy results from choosing the latter. The only point which has to be observed is that the dark-room light is a pure red, and free from any trace of green or yellow. In most cases this requirement is already met, and, if not, it is a simple matter to fit a properly tested "safe-light" to the existing lamp.

Although the full advantage of the ortho' plate cannot be obtained unless a yellow, or greenish-yellow, colour-filter be used, a considerable improvement in the quality of the negative can be obtained without it. In the case of very florid, sunburnt, or brunette complexions, a very long exposure is necessary with an ordinary plate to avoid a dusky appearance, but with the ortho' plate a slight increase beyond the normal will be all that is necessary. With badly-freckled skins, especially when these occur in conjunction with deep yellow or reddish hair, as is very frequently the case, it is very desirable to use a light yellow screen, which will necessitate doubling the exposure, but, when using a plate of 500 H. & D., this should prove no deterrent. With such sitters the improvement by so doing is most conspicuous. If a test for this be desired a group of two persons—one with a healthy tan and the other with a delicate pink and white skin—will convince the most incredulous. A great improvement is also obtained with white or very light draperies, although with these the best results are only to be obtained by using backed plates or films

There are now many self-screened isochromatic plates upon the market, and these have been found to

yield excellent results in the studio, being certainly better than the unscreened ortho' plate. From the nature of their manufacture a full exposure is needed to bring out their true capabilities, and few portrait negatives receive this. For this reason we recommend the use of a colour filter, whether the ortho' plate be a screened one or not. The cost of a colour filter of good optical quality of sufficient size to be used with a large portrait lens is rather a serious item, and one of poor quality will impair the definition of the best lens. This has perhaps deterred many photographers from giving orthochromatic work a fair trial. Fortunately, there is a cheap and easy way of overcoming this obstacle. Most of the leading makers issue thin sheets of gelatine, dyed to the proper tint, at a cost of a few pence per square inch, and a piece of this cut to the requisite size may be fitted either inside the lens tube or mounted upon a cardboard cut-out immediately behind the lens. The former position is preferable, as the gelatine is protected from both atmospheric influences and finger marks or scratches.

It is when using artificial light that the full advantage of the colour-sensitive plate is adequately displayed. The half-watt lamp is rapidly ousting other forms of illuminant, and has no disadvantages except the somewhat yellow tinge of the rays. This is entirely removed by the use of the ortho' plate, which is sensitive to such rays, and which in this case does not (for the ordinary sitters) require a colour screen. It has been claimed that an iso plate bearing the same H. & D. number as an ordinary plate requires only half the exposure of the latter when used with half-watt lamps, and upon trial we have found the claim to be approximately correct. Those who have had much experience with arc lamps, particularly of the enclosed type, are aware of their unkind treatment of the freckled or red-haired sitter. Here, again, the ortho' plate scores if used with a pale yellow screen, which practically brings the light on a level with that emitted by the half watt.

All the advantages of the ortho' plate are, of course, possessed in even a higher degree by the panchromatic, and for very highly coloured draperies, scarlet uniforms, and the like, these should always be used; but it is hard to persuade the average photographer to load and develop in absolute darkness, and therefore he is likely to use the ortho' plate for all subjects within its scope.

PHOTOGRAPHY FOR THE NEWSPAPERS.

[Below we continue the publication of a series of eight chapters on the supply of photographs to the newspapers written by Mr. W. Lancelot Vining, until recently art editor of the "Sunday Pictorial." So far as we know this is the first occasion on which the subject has been dealt with by a writer intimately acquainted with the production of an illustrated newspaper, and considering the matter from the angle of the art editor. Mr. Vining, who has spent his life in press photography, first as a free-lance and subsequently as a press photographer on the "Daily Graphic" and "Daily Mirror," deals in the current chapters with flashlight work and with portraits and figures. His two last chapters will appear in our issue of July 29.—Eds. "B.J."]

V.—FLASHLIGHT.

Every photographer having press-work in his mind should be able to get a good photograph by means of artificial light made by flash-light powder. The lamp required is of no great size, and can be carried in the pocket. There are several makes on the market, and if handled according to the makers' instructions, will give very little trouble. When you set out to cover any event, you can never be sure that you will not be called upon to take a photograph in some dark place, or a portrait in a very bad light, and many a cheque has been lost to a photographer because he had no flash-lamp with him. Interiors, and even portraits indoors, are greatly improved by giving a small flash at the end of a daylight exposure. The exact amount of powder to be used is very important. The majority of photographers use far too much. A little home practice will soon put you right over this, and give you the amount of powder to be used to get a good result, without overtaxing the patience of your sitter, whom you will often find can sit quite still for three seconds, but not for six, and this is where the little flash at the end of the day-light exposure scores. The negative will also be found to be bright and crisp, and the print a good one for reproduction.

Now, I want to give all my readers a warning. Never handle flash-powder except with the greatest care. You may use it every day, as I have done, during the winter months, and although I have always entertained a holy horror for the stuff, and handled it as I would gunpowder, I have paid three visits to Charing Cross Hospital to have my hands dressed. There is no need to get "wind up," but never hurry, or allow yourself to be rushed, and keep as far away as you can from other people.

Very often when flashing at a public meeting you will be told to hurry up, etc., etc. Well, this is just the time to go slow; don't lose your head or get flustered. If possible, have your camera in position and everything at hand before the chairman announces that a photograph will now be taken for the "Sunday Pictorial." All you will then have to do is to draw your slide, put out your powder, ask for the attention of the group and expose. There are several methods of exposing at these times, but I think the best and safest is by a cap on the lens in preference to working the shutter by ball and tube. The latter has been known to fail, and when using a cap you will never be worried at the last minute wondering whether you remembered to set the shutter; but when using a cap, you must make quite sure that your shutter has remained open since you focussed the group.

Never fire the powder where there is a downward draught, and this often occurs in halls. Look out for open skylights and windows in the roof or high up in the walls. Hold even the smallest flash high above your head and always wear a leather glove on the hand holding the tray.

You may have some trouble in obtaining permission to flash some important gathering, and then only receive it on the promise that there will be no smoke. In this case I advise you to find a quick way out of the hall beforehand so that you can get well clear of the hall before the smoke, which you are bound to make with a big flash, has had time to hit the roof and descend in the form of a miniature fog upon the audience. Their remarks would not interest you, although they would very much like you to hear them. I remember on one occasion when in the Midlands at election time I was brought back into the hall after letting off a big flash to hear a few special remarks from the chairman on "Truth in rela-

tion to photographers." I could just see the speaker through what was certainly a rather thick mist, while the coughing drowned his voice, but I had obtained my picture.

Always measure your powder by spoon-fulls and keep one spoon specially for this purpose. "Borrow" one from the silver drawer at home, but be sure that it never gets back again among the others, because, I believe, the powder is poisonous; it certainly kills fish. I made six very small flashes in a friend's drawing-room, and accidently let some of the ash fall into his bowl of goldfish. Next morning they were found to have "gone West." Always keep your flash-lamp very clean; a stiff nail brush is all that is required.

I do not advise flashing in the open unless the air is very dry, and in any case do not put the powder out until the very last minute, otherwise you risk an explosion if the powder becomes at all caked, as it certainly will if the air is at all damp.

A very good brand of plate to use when using artificial light is a rapid orthochromatic and a developer which has not the tendency to give strong contrasts. With care, any developer can be made to give a good result; but as there is always a risk of under-exposure which would give harsh contrasts, no bromide should be used, and the developer should be diluted with water. My favourite developer for this work is hydroquinone-eikonogen, made up as follows:—

A.	Hydrequinone	½ oz.
	Eikonogen	½ oz.
	Sodium sulphite	2½ oz.
	Hot water to	45 oz.
B	Sodium carbonate	2½ oz.
	Hot water	15 oz.

A. 3 oz. B. 1 oz. Water 3 oz.

A good negative for enlarging should be obtained in about eight minutes.

Success in group and portrait work by flashlight depends a great deal upon the arrangement of the light and the sitter. The chief mistake made is to have the light at too low a level. Reflectors play a very important part in obtaining good results, but the correct manipulation of these can only be proved by experiment, but it is quite worth while spending some time doing this. When possible get a fair amount of contrast between the dress and your background. Always aim at a result which will reproduce well, even if reproduced small size.

VI.—PORTRAITS AND FIGURES.

Portraits play a very big part in press-work, and every correspondent should be able to obtain a good result or set to work to practise until he has more or less mastered the art of lighting his subject in a manner to suit his or her features.

A photograph of any person should always include the complete face and top of the head, the feet we do not worry about so much. I make this remark because the "Sunday Pictorial" is constantly receiving plates or prints which have part of the features missing, the edge of the plate cutting right through the face. Retouchers do not like having to guess at the missing half of the face of a person they have never seen, and the subject in question usually has some very pertinent remarks to make about the result. A photograph of this description would, of course, not be used unless very important. Another fault which is very common with amateur photographers is the small size of the figure on the negative. I recently received a quarter-plate print of a man who had made a very important arrest, and which I was very anxious to use. The size of the figure was ¾ inch, and the legs had been cut off, while the angle was 45 degrees and the whole was out of focus. By the time I had enlarged the figure to half-plate and had it worked up I very much doubt whether even his friends knew him. Both these faults can be cured by getting on "speaking terms" with your view finder. Of course there is no excuse at all if your camera is a reflex. Make a few experiments and you will soon find out the correct distance to stand from your subject to obtain a full-length figure. When using a 5 x 4 upright, the image should never be less than 3 in. This will give clear details and ought to be obtained when using a 6-in. lens on a 5 x 4 plate at about 5 yards. It is very important that the view in your finder agrees with your focussing screen. When out to take a portrait for publication get a full-length, as well as head and shoulders, as you never can tell what an art editor will want to do with the story, or the shape of the space he is keeping. You might think the story was worth a picture the size of a postage stamp, while it was wanted to go the full length of the front page. Having made sure of your portrait, ask your subject to let you have a "lifey" snap—working in the garden; walking in the street. Get them interested, and try and give the result a natural touch. Introduce a pretty child or an animal (two very safe cards to play). Always try and get a bright result, however dull your subject may be. An art editor is always trying to produce a bright paper, and is always on the look-out for a bull's-eye for every page, and there is no reason why your photograph should not be the one selected and reproduced at a size which will bring a double fee.

"What dress shall I wear?" This question will always be put to you when your sitter is a female. Dress and its colour plays a very important part in photography, and more often than not does not receive the attention that it should. Always use a fast isochromatic plate when possible, and when the light is very good a 1½-times screen. This will save a great deal of retouching. Don't forget that pink and yellow come out grey; scarlet, a dark grey. Dark red, brown and dark green print up black. Silver ornaments give a better result than gold, while diamonds and all stones with great sparkle should be smeared with soap to deaden the reflection.

When taking photographs for publication, there are a great many things which must be taken into consideration, and I think that backgrounds can easily be put at the head of the list. Why do so many photographers choose a red-brick wall, and having made this bad start, make things very much worse by standing their subject as close to it as possible? Very few portraits go through the process of reproduction without having a certain amount of work put on the face by an artist retoucher. This we expect, but we do not want to lose valuable time painting out unsuitable backgrounds, when a little thought at the time of exposing would save all this extra work, which by the way has to be paid for. When possible, choose a plain back in contrast to the dress and colour of the subject, as the result to be aimed at every time is a good printing negative. This may not be artistic, but that is not everything in press-work. A sheet, tablecloth, or even a newspaper is better than a brick wall, but if a wall has to be used, get your subject as far away from it as possible, and it will be then out of focus. Trees and hedges also make very bad backgrounds if the subjects are stood close up against them.

Collecting Portraits.

When collecting a portrait a promise can always be made that the original will be quickly returned, undamaged and clean. Write the name and initials of the person on the back clearly, and be quite sure it is the right person, and also the address to which it is to be returned. When it reaches the office it will be copied and returned at once. It is also just as well to find out who owns the copyright, and to put that on the back as well. We may have to pay the photographer as well as the collector.

The News Photograph.

What shall I photograph? This is a question that I am often being asked, and is one that is not at all easy to answer; so much depends on the person behind the camera. I know many photographers who can take a subject of no topical interest, and by the method in which they handle it produce a photograph which is quickly published, and I also know

many photographers who would pass this same subject by as quite useless. News photographs can be placed in two classes—dated and undated. The former must be handled quickly, even if you are the only photographer at the event. Never stop to develop and print, but proceed as instructed in Chapter 4. Don't overdo the number of plates you expose. More than three pictures of one story are very rarely published these days, except the big news event. Find out the principal items of the event you are covering, and work on these. The "undated" events or subjects give you more time, and provided you have no one in competition, there is no reason why you should not develop your plates and make enlargements from them if you wish, but if you have no enlarger, send the negatives for the office to enlarge. Most interesting subjects require a little story to explain them. Write enough to fully explain the photograph, and the caption-writer will condense it into the required number of lines.

Arranging "Stunts."

When a local event is fixed, and you think it will interest a paper, write to the art editor giving full particulars and offer to cover it for him. Mention any expenses that may occur. He will then do one of three things—refuse your offer, give you a definite order, or tell you to send prints on approval. If you have secured the exclusive photographic rights, state this in your letter. In this event a paper is often quite willing to pay a fee, so that their photographer can attend, and this will save the correspondent a great deal of trouble.

Make your arrangements for a good position beforehand, and there ought to be no difficulty over this. In fact, a local man is always better treated in this respect than a stranger. Be on the spot early. Never rush up at the last minute and then be surprised and cross if you cannot reach your position, and fail to get good pictures. When arranging your position, do not forget to allow for the position the sun will be in at the time you will be exposing. Sometimes it will be necessary to get a posed group. In this case always see the chairman as early as possible, and before he gets busy tell him exactly what you want to do, and the time you will want to take your photograph. You may have an idea for a "stunt" which would produce five or six good and interesting pictures. You can obtain these and send around on approval, or write to a paper and put it up to them. Give full particulars and what it would cost, also the fee you would require; but always remember one thing when dealing with stunts, it is never a very wise thing to give away ideas for pictures.

W. Lancelot Vining.

(To be continued.)

NOTES ON THE USE OF PANCHROMATIC PLATES.

An amateur with progressive ideas and powers of observation soon tires of producing bald-headed snapshots with dead white skies such as are obtained with ordinary ortho plates and films.

Relief is sought by the use of ortho filters (three to five times) to get the desired cloud effects, but one is hampered by the reduced light and lengthened exposure frequently making it impossible to use a hand camera with an *f*/8 lens.

Even the five times ortho screen, which is the maximum for efficient correction, does not give the best results, and many turn to the anti-screen or non-filter plate, which is alleged to give full correction without any filter except that incorporated in the film.

Better rendering is certainly obtained, but still those clouds elude us, and a three times filter has to be used to get them registered on the negative effectively.

At this stage we are a little better off than with an ortho plate and five times filter in the matter of exposure, assuming both plates to be Wynne 90, a fair average speed for this class of plate; but still we are not happy, for now our negative is over-corrected, and the results are unreal. At last we turn to the panchromatic plate (about which many amateurs are unnecessarily timid), and find that we are better off in the matter of exposure, whilst the other troubles of development, etc., are more apparent than real.

We can get at least two varieties of panchro. plates with a speed of Wynne 110, which will give all the correction required by means of a one and a-half, two or three times filter, and for outdoor work we shall not require more than two times as a rule.

With a hand camera of lens aperture *f*/4.5 I can take good outdoor exposures at *f*/8 or *f* 5.6 and a two or three times screen at 1/25 sec., and have to be careful to avoid over-exposure during this present month of April between 9 a.m. and 5 p.m., and the negatives show perfect colour correction and beautiful cloud renderings.

Too much of a bogey is made of the loading and development, as I will endeavour to show.

Loading can be done without difficulty in absolutely dark conditions if one remembers that plates are packed in pairs film to film. If plates are backed (and, personally, I use no other) the rough backing can be felt with the tip of the finger, and I never make a mistake in loading a double back holder.

Development is equally simple if properly carried out. If no dark-room is available, plates can be loaded in the dark in a developing tank by touch, as in loading plate holders. There are many tank developers to be bought and many formulæ available if one prefers to make up developer at home.

Any degree of contrast can be obtained by varying the time of development, and a few experiments will soon make any one *au fait* with a particular developer.

If quick development is to be done in a dark-room time and temperature methods can be employed as before, covering the dish effectively and switching on the light to observe the time, switching off again when ready to rinse and fix the negative. As above contrast can be regulated by time of development.

Factorial development can be done equally easily with a Wratten Green safe light. Many state that they cannot see to develop by this light, but at least one can see the image flash up and note the time by a stop watch, afterwards covering the dish and switching on the light to time development, switching off again to rinse and fix the plate by the aid of the Green safe light.

Contrast can be regulated by varying the factor. A new method is available to us now in the use of the Ilford preparation called Desensitol, a concentrated red dye, which is diluted for use to 1 in 50; a plate bathed in this can be developed in a bright yellow light after one minute. Like all new methods, it has drawbacks, which will doubtless be overcome in time.

The dye stains the film pink, and does not always remove by prolonged washing.

If the staining is even tinted it is not serious, but sometimes it is uneven and patchy, and, further, an apparently stainless plate will sometimes show purple patches when dry.

The use of dilute hydrochloric is recommended in such cases, but even with the alum bath there is a tendency to frill.

Another drawback, but not a serious one, is the alteration of the time factor in factorial development, but as factorial development is not necessary in a bright yellow light this does not matter very much.

Mr. Raymond Crowther, who is writing on this subject in

the "British Journal" from time to time, will doubtless discover for us in time a stainless desensitiser, and then this method will be perfect.

For the present I prefer either tank development or factorial development with a green safe light.

It may be mentioned at this point that although the Ilford Co. warn panchromatic plate users that their plates are unsafe in a green safe light, I have developed several of their plates by this means, using pyro soda and factorial development without a trace of fog on any plate.

Possibly this is due to the fact that the black backing dissolves and stains the developer black, making it safe against the green light.

On the superior colour rendering and cloud effects that are obtained with a panchro. plate and one and a-half to three times filter I need not dilate here.

Let any reader choose a suitable outdoor subject, and try for himself a set of negatives—ortho, with and without filter; self-screen, with and without filter; and, finally, panchromatic, with filter—and compare results.

The panchro. plate and filter holds the field against all others for speed, combined with a given degree of colour correction, and no one who gets experienced in their use and management should want to go back to other plates for outdoor subjects or daylight portraiture.

HENRY N. HOLLAND.

DEFINITION IN PORTRAITURE.

[In his Paris Notes some weeks ago M. L. P. Clerc referred to a recent paper and demonstration before the French Photographic Society by M. G. Cromer on the employment of a lens of large aperture for portraiture for the sake of its "looking round" effect, and mentioned the effective use which had been made of an objective having a diaphragm of 5 inches diameter. M. Cromer's full paper having now been published by the French Photographic Society, we take the opportunity of printing a translation of it, in making which we have to acknowledge the kindness of M. Cromer in elucidating one or two items which appeared insufficiently explicit in the French text.—EDS. "B.J."]

PERHAPS the most insurmountable obstacle which is encountered by those endeavouring to produce by photography works having the quality of art is that which relates to definition. The difficulty appears the greater from the fact that, as a result of optical conditions, the definition of a photographic portrait is localised in the parts of the subject which are in exact focus, whilst other parts are rendered more or less "woolly" in appearance; part of the outlines is obtained quite sharp against the background, whilst the rest suffers from diffusion or fuzziness.

Most of those who have studied this question of definition in relation to portraiture have taken the view that it is due only to the greater defining powers of the lens, as compared with that of our eyes, and have, therefore, sought to break up this sharpness in order to obtain a more exact reproduction of nature. Claudet, in 1866, suggested altering the focal length of a lens during the time of exposure by separating the front and rear components. He aimed at reducing the excessive sharpness of some parts, and the too great fuzziness of others by bringing them all into the plane of sharp focus. In the same year Dallmeyer introduced his famous soft-focus lens, a modification of the Petzval objective, in which he obtained an analogous result more easily than Claudet by slightly unscreening the rear lens before exposure. Much later, in 1904, MM. Puyo and de la Pulligny introduced their artistic lenses, yielding diffusion by residues of chromatic aberration, and soon afterwards there appeared the Eidoscope of Hermagis, in which diffusion resulted from spherical aberration; the Dallmeyer-Bergheim, etc. [M. Cromer is in error respecting the date of introduction of the last named, which was about 1895.—EDS., "B.J."]. In the hands of many skilful portrait photographers these lenses have produced remarkable results; but, in my opinion, they serve only to hide, by their diffusion, the definition which is the ideal of the artistic photographer.

Shortly before 1900 M. Boissonnas, of Geneva, following suggestions of the painter Darier, made a start on what, I think, is the correct path, by studying what he termed binocular photography. We do not know what was Darier's idea; but it is easy to imagine it by recalling Wheatstone's demonstration of double vision. Since the draughtsman looks at his model with both eyes, he sees a little more of the left side of his model with his right eye, and a little more of the right side with his left eye. His drawing is thus the synthesis of these two aspects seen simultaneously. The lens, however, scans over a single angle, and views Nature as a one-eyed man would do. In order to imitate the unconscious process of the draughtsman by photography, Boissonnas employed on his camera two lenses, paired as for stereoscopic photography. By slightly inclining the lenses, he caused the two images to be superimposed on the ground glass. In this way he produced the curious portraits exhibited by him in Paris in 1900. But the process had two defects. In the first place, the superimposition of the two images was a delicate operation, and in taking a portrait it is necessary to work quickly to avoid fatiguing the sitter.

Moreover, it is well known that the exact registration of two images of the same subject taken with two lenses under different angles cannot be done. In the process of Boissonnas, the two lenses were mounted horizontally, and, therefore, the images could be registered as regards their height, but not as regards their width. Thus the outlines approximating to the vertical were sharply doubled, enlarging the image obtained, and though nearly horizontal lines were almost sharp, those running nearly vertical were never so.

I have endeavoured to find a solution of this problem which has occupied experimenters since Claudet; and I first noticed that the works of artists, draughtsmen and engravers, as well as painters, of every period of school, with rare exceptions, never employ diffused definition in the rendering of Nature. Their work may be done in masses or broad effects obtained by reducing or omitting disturbing details, but the drawing and the essential outlines are always firmly defined. In short, whatever the kind of representation, artists reproduce what they see within limits comparable to those of normal human vision in the examination of a scene.

On the other hand, the fertile idea of Darier, supplemented by the experiments of Boissonnas, gives the key to this habit among artists to those photographers who are seeking to infuse art into the works produced with a lens. The latter does not record as do our two eyes; but, as a one-eyed person. I venture to think that in this lies the true explanation of the definition produced in photographs.

The direction in which to experiment was thus plainly indicated. *We require a lens able, first, to see binocularly; and, second, to define the image within the limits of precision of a normal eye.*

An observation of Brewster's pointed me quickly to the solution of the problem so far as binocular vision is concerned. The English physicist noticed that lenses of too large diameter introduce into the photograph parts of the subject which, with our two eyes, we see only by alternately turning the head to

the left and the right. It, therefore, seemed probable that lenses of suitable diameter would see the sitter as we do.

Practice showed the correctness of this assumption, and that the best rendering in this respect is obtained with lens of 5 inches or about 13.5 cm. diameter. Those of 4 inches diameter are large enough for this purpose, but those of 6 inches are too large, and, moreover, are of inconveniently great focal length. My experiments were made with a lens of 5 inches diameter of aperture.

As a control of the first results, I made an experiment for the purpose of proving that a lens of this size views the subject from different angles, as do the two lenses of a stereoscopic camera. Choosing an immobile subject, a plaster bust, I took a negative after having placed behind the front lens a piece of black card having a circular aperture of 3.25 cm. diameter, which was disposed tangentially at the right-hand edge of the lens. Focussing was done on the eyes, before placing this mask in position, with the lens at full aperture. This first negative was made on the left-hand half of the plate by means of the customary repeating back.

I next made a second negative under the same conditions, except that the mask was turned to bring the aperture tangentially at the left-hand edge of the lens, and the exposure made on the right-hand half of the same plate by sliding over the repeating back. A pair of negatives was thus obtained on the one plate representing the two views of the subject. If, now, the lens sees binocularly, we should have, on making positive prints and mounting them at a separation of 6.5 cm. between corresponding points, a stereoscopic print, exhibiting the customary relief. The result conclusively showed this to be the case; and it can, therefore, be admitted that a lens of 5 inches diameter of aperture renders modelling as seen by the eyes.

But, as regards sharpness of definition, the problem still remains to be solved. With this lens the definition of parts of the image in sharp focus was too good, but of others, insufficient. As regards this question, I had noticed that with portrait lenses, particularly those of old construction, the margin is far from being equivalent in effect to the central part, and the sharpness of the image comes chiefly from the midway region of the lens. By masking this portion more or less completely by a disc of black card placed at the centre of the front lens, we ought to obtain less perfect images, and therefore more nearly in correspondence with those seen by the eyes. This was the first means tried for the production of the desired normal rendering.

It should be noted that the use of a disc in this way does not involve appreciable increase of the time of exposure. If an objective of old type is used, such a disc covers scarcely a quarter of the surface which can be utilised at full aperture; and if it is borne in mind that, without the disc, it is necessary to stop down for the sake of depth of focus, it will be understood that the use of the disc does not reduce the useful speed of the lens. The disc used against the front lens can be replaced by one of suitable diameter central in the position of the diaphragm.

An alternative means for remedying the excess of sharpness can be used, and has the advantages of leaving the speed of the lens unaffected, and of not requiring a lens of old type. Moreover, it can be very readily modified according to the degree of diffusion desired or admitted. This second method consists in interposing in the path of the image-forming rays a transparent screen, so as to alter the course of the rays slightly. The clear gelatine sheets used by photo-engravers answer excellently, if of the utmost purity. I employ them from 15/100 to 30/100 thickness equivalent to .006 to .012 of an inch. The thinner the screen, of course, the less the diffusion.

Some experiment has been devoted to finding the best position for such a screen. I have tried using it in the plane of the diaphragm between the two glasses of the back combination, and lastly behind the whole lens at distances ranging from .1 to 20 cm. from the back combination. Of these various positions, the worst seems to be that in the plane of the diaphragm for the screen then tends to grey the image. The position behind the lens appears to be the best. In this position the screen produces the minimum of greying, and gives less diffusion as it is moved away from the lens in the direction of the plate, the latitude in this respect being an important advantage.

For the mounting of the screen, a collar may be secured round the rear part of the lens tube, and serves to support a horizontal rod parallel to the optical axis, placed below this axis and extending in the direction of the plate. The screen is mounted on a light cardboard frame, to which is fixed midway at the top perpendicularly to its surface a tube which slides stiffly on the rod. Thus we have only to remove the ground glass from the camera in order to fix the screen on the rod and can move it along the latter as required. Also the screen can be readily exchanged for a thinner or thicker one. I would add that the gelatine screen can be used with any lens, and will be found a novel and practical means of securing diffusion without the aid of special fitments. All that is necessary is to fit the screen to the camera in the same manner as a light-filter, preferably behind the lens. In place of the gelatine screen one of extra thin glass, such as a microscopic cover glass, can be used. The perfect transparence of glass avoids all trace of greying effect on the negatives.

The use of this somewhat thicker screen serves to show the way in which the process improves the even character of the image. This image appears on the ground glass as formed of several images, which do not coincide, or only very approximately, in the parts which are in sharp focus. The excessively sharp focus of these parts is thus modified. In the parts which are not in focus these various images are slightly separated, and the outlines, instead of being unpleasantly woolly as usual, are formed by a certain number of fairly sharp and adjacent lines, which impart a much firmer character to the definition, in the manner of the pencil strokes of the draughtsman. It can be said that a positive increase of depth of focus is produced in this way.

I will now refer to a third means which I have studied for overcoming the excessive sharpness given by portrait lenses. It is, however, applicable only to lenses of the old types of relatively small aperture.

Proceeding from the observation that these lenses can be opened out whilst still giving sufficient depth of field for portraiture, I enlarged the fixed diaphragm and obtained images of much more even definition.

In reference to the use of large lenses, it is often stated that if of greater diameter (of diaphragm) than 10 cm., they produce deformation of the image by recording parts of the subject, which the two eyes cannot see simultaneously. (M. Cromer here projected a portrait in illustration of the incorrectness of this statement.) The result I now show you was made with a lens of 5 inches diameter (= 13.3 cm.), the same one used in making the stereoscopic pair of negatives previously mentioned. Now, just as it has been shown in the stereoscope that the relief obtained by the use of this lens was not exaggerated, but was, if anything, less than the regular stereoscopic relief, so in the single portrait we notice how small is the difference of view point in the two images. In this experiment the camera was 13 ft. (4 m.) from the subject. If we take up a position at the same distance from any sitter, and close first one eye and then the other, we shall not perceive less of the right side of the model with our left eye and of the left side with our right eye than is recorded by our 5-in. (diameter) lens when employing the right-hand and left-hand portions of its front glass. Therefore I repeat that lenses of 4 inches, and particularly 5 inches, diameter are solely capable of seeing binocularly without deformation, and that it is not until lenses of 6 inches diameter are used that there is occasion to fear the defective drawing which is commonly attributed to lens of diameter greater than 10 cm. In illustration of this I show some examples made with a lens of 5 inches diameter, in which the sharp definition has been reduced by one of the means described above. (M. Cromer also showed two examples made in the same manner by M. Benjamin, the well-known Parisian photographer.)

B

To conclude, when it is wished to obtain the most realistic and striking portraits, we must have recourse to lenses of sufficiently large diameter, as was done by Adam Salomon, Nadar, Carjat, Bertall, whose most beautiful work challenges comparison with much of recent date. Such lenses should be free from chromatic aberration, and employed in conjunction with one or other of the screens described. In this way the extreme sharpness of definition will be broken up and the quality of binocular vision will be utilised.

G. CROMER

STEREOSCOPIC LENS SEPARATION FOR NEAR OBJECTS.

THE important article on the above subject which appeared in the "B. J." of June 24th is very welcome, and its author, Mr. E. J. Bedford, deserves the thanks of all who are interested in the improvement of stereoscopic practice. He has carried out a systematic and graduated series of experiments, and has given some informative samples of the results, together with the technical details which enable us to examine them, and, if necessary, to criticise them intelligently. In commenting on an article of this kind, which embodies the fruits of much painstaking labour and puts them at our disposal, criticism must be postponed until expression has been given to that appreciation which in this case it is both easy and pleasant to accord. It may be said at once that the three examples of stereo prints shown seem fully to bear out Mr. Bedford's remarks concerning them. The subject he has chosen to illustrate in all three cases consists of a simple grouping of a 1.5 in. cube, a small sharply pointed volute shell, and a large match. The print numbered 1, taken with $\frac{5}{8}$ in. lens separation, gives an agreeable and sufficient perspective relief, and the size and distance of the image do not strike the observer as incorrect. No. 3, on the other hand, which is given as an example of how not to do it, taken with $2\frac{3}{4}$ in. lens separation, cannot be viewed without a sense of discomfort and unreality, and is accurately noted as presenting exaggerated perspective. No. 2 is intermediate, and for present purposes may be neglected. Mr. Bedford's introductory observations on the subject of stereoscopic relief in general are of a most admirable common-sense kind. The aim of stereoscopy should be to attain the natural effect and to eliminate everything that is artificial and untrue.

The first remark that has to be made in the nature of criticism concerns a very amiably expressed *obiter dictum* of Mr. Bedford to the effect that practice, as exemplified by his results, sometimes differs from theory. Photographic optics consists of a very simple form of "straight through" geometry, its only difficulty being that it must be treated as a geometry of three dimensions, not, as is sometimes done, of two, or even of one. It is accepted and acted on as accurate not only in text books, but in the laboratory, where work of the utmost precision has to be executed. Theory solved the abstruse problem of correct mapping from obliquely taken aeroplane negatives, when no account of rule-of-thumb experiment would have succeeded. If theory predicts results which differ from those obtained in practice, then either the theory or the practice must be in fault. This second contingent must be borne in mind. It may be that in practice some of the rules laid down in theory have been neglected.

The present writer is an old stereoscopic practitioner of some twenty five years' standing. Of late he has for various reasons turned theorist, and does his photography by the aid of *fs.* and *xs.* and right lines and angles. As such he has had the privilege from time to time of contributing some practical suggestions to the readers of the "B. J." for the solution of various photographic difficulties and the removal of certain misconceptions. He can safely say that he learnt more about the principles and practice of stereoscopic photography in half an hour, with the aid of a pipe, a pencil and a piece of paper, than in five years' enthusiastic camera making and picture taking. While practice, in the person of Mr. Bedford, was straining its eyes and staining its fingers in experimental work, theory, in the person of the present writer, was injuring its brain cortex in the pursuit of this extremely elusive will-of-the-wisp of the stereoscopic photography of small objects, discovering at every step new practical difficulties which had to be overcome if the investigations were to be of any use. The result took the form of two very dry and unattractive articles which appeared in these columns in April and May of last year (1920). Information on this subject had been asked for by practical workers; and when the validity of the rules given seems to be not only called in question, but even refuted, by the specimen stereo prints sent in by Mr. Bedford and the details accompanying them, it becomes necessary for the theorist either to stand to his guns and point out the principles which have been lost sight of by the photographer, or to acknowledge himself in error and retire as gracefully as he can.

In ordinary single lens photography there is only one problem to be considered—namely, how and from what point to view the prints in order to secure the natural perspective. In the strictly technical sense no mistake can be made in the taking or in the mounting of single photographs. But in stereo photography the problem is three-fold, and its three elements are inseperably interwoven. The taking, the mounting and the viewing of the photographs possess equal importance in determining the accuracy or otherwise of the resultant image. A technical mistake made at any of these three stages introduces an error which cannot be entirely rectified. In both branches of photography grave *artistic* errors made be made in the choice of subject and view point; and it by no means follows that because we see what is true to nature the result will be pleasant to the eyes or free from violent and disagreeable perspective. This self evident fact must not be lost sight of.

Mr. Bedford, very strangely, has devoted himself altogether to the problem of the taking of the stereoscopic negatives. To the proper mounting of the prints he pays no attention whatever, beyond stating that the print centres should not be more than $2\frac{1}{2}$ or $2\frac{3}{4}$ in. apart. The extraordinary result of this last rule will appear when we come to consider his print No. 3. As regards the viewing of the prints he contents himself with the statement, "This will suit any kind of stereoscope in general use."

In the taking of the photographs he appears to have adopted, if not a theory, at least a working hypothesis or principle of his own. Throughout his article he seems to assume that the photographs must be the same size as the required image: if the image is to be natural size the photographs must be so too; if twice natural size the photographs must be on a scale twice that of nature. This when it can be done, certainly makes it very easy for the eyes to receive the impression of size; but it would be most unfortunate if we had to accept it as a binding condition. What will happen if we try to photograph an object 4 in. wide, and present it natural size? Since the stereo prints cannot at most exceed three inches in width according to his own rule, this, on his hypothesis, will be impossible. And if we wish to photograph a cathedral, must we be content with a visual image on a scale of 1.400 or less? Does the rule hold good for large distant objects as well as for small and near ones? If not, at what point does it begin to change? Is there a gradual alteration in the necessary

equality of photograph to image as the latter recedes, or is there a *per saltem* change at some critical distance, like the sudden mutations which biologists are beginning to recognise in the processes of evolution? In fine, is stereoscopy, like every other branch of photography, an exact art, with clear-cut unalterable rules which extend over the whole field from the nearest point of distinct vision to infinity, or must it for ever be practised through the rough medium of rule-of-thumb approximations—any view to any stereoscope—in which we blunder on by experiment and error, and do our best to produce eventually a mental illusion good enough to pass muster as somewhat akin to reality? If the latter, then we can understand why so many technical and artistic workers of the highest class look on the keen stereo-photographer much as we regard a child who is lost in admiration of a rag doll.

But the more emphatically the theorist thus laments the defective practice of his day, the ruder must be the jolt he receives when he examines Mr. Bedford's results, which seem to show that theory, like the law, "is a hass." Theory decrees that if the stereo prints are the same size as the required image the two prints must be super-imposed, in order that the eyes may converge as in nature; and common-sense informs us that this must be so. Yet Mr. Bedford, in his No. 1, mounts his prints side by side, with wide separation between corresponding points, and secures an admirable effect. Theory decrees that if a natural size image is to be produced the taking lenses must be eye distance apart. Yet No. 1 is taken with only ⅛ in. in separation, while No. 3, which approximates to theory (2¼ in. instead of 2½ in.), is by comparison a complete failure.

However, a careful examination enables theory to advance a few considerations in its own defence. In fact, having languished for a time under what seemed a knock-out blow, it now holds up its head again with all the robust self-confidence of a sturdy convalescent.

Mr. Bedford's thesis throughout his article is that it is desirable to reproduce a natural effect: "the whole process of stereo photography is to present objects as seen in nature." He wishes us to see the group of objects he has photographed exactly as he saw them himself, and at the same distance of 12 in. from the eyes. But No. 1 does not do this at all. If the left eye, viewing the original objects, were placed so as to see the view shown in the left-hand prints, the right eye could not possibly see the right-hand view: it would much more nearly see the view given by the right print in No. 3. As already pointed out, the fact that No. 3 is disagreeable and difficult to view does not by itself prove that it is untrue to nature. The group quite legitimately chosen for the photographs is of considerable depth, and, as arranged, has many projecting points and rapidly changing contours. When examining actual objects of this sort we can either turn them about in our hand or we can change our position. In the stereoscope no change of view point is possible; and if the perspective difference between right and left eye entails large occulations of important areas of the subject the imagination of the observer cannot be expected to fill the gaps, and a painful sense of confusion results. In No. 3, a key portion of the whole composition—the far end of the shell—is hidden in the right-hand print by the projecting end of the match, while only about two-thirds of the back edge of the cube is common to both eyes. That this sense of confusion depends upon the nature of the objects photographed can easily be proved by arranging a small group of articles criss-cross and viewing them from a near point without movement of the head. We are led to the conclusion that this particular subject chosen by Mr. Bedford for illustration is not one suited for stereoscopic reproduction at 12 in. distance. This in no way discounts its value, or the propriety of its use for test purposes, but it emphasises once again the necessity of avoiding what is bound to produce an unpleasing result. If the object chosen had been a butterfly, mounted in the usual way, and only some ¼ in. or so in depth, it is very questionable whether No. 1 would have emerged at all so triumphantly: it is much more likely that No. 3 would possess a pronounced superiority, at least in the clearness and distinctness of its stereoscopic relief.

No. 1 view shows us, in fact, a radical departure by Mr. Bedford from his thesis, for it presents his group of objects with a perspective considerably *less* that that of nature at 12 in., and the result is effective and pleasing. Let us apply theory to discover why this is so.

In No. 1 the lens separation used (⅛ in.) is only ¼ that of the eyes. The image, therefore, when properly viewed, would be projected to a distance of nearly 4 ft., and magnified four diameters. Corresponding points in the two prints—say, the upper ends of the match—should be mounted in this case 1.8 in. apart instead of the 2.8 in. shown in the prints; so that there is an error of 1 in. If the popular sphero-prism stereoscope is used to view the print this error is more than corrected by the resultant inward shift of both images, which thereby become smaller and coalesce at a point nearer than 4 ft. As the slide is probably brought much nearer to the eyes than the proper distance of 12 in., the image is again brought nearer, but not further reduced. The cumulative result which comes out of all this is that there is no very extreme departure from theory in essential respects, and the eyes, without effort or strain of any kind, can see a very satisfactory and convincing stereoscopic group. As regards the apparent size, the presence of the match is a very compelling feature. Even if the utmost accuracy were secured it is almost certain that the mind would refuse to accept the reality of an 8 in. match, and this fact coerces the judgment into fixing the size and distance of the whole group. If a non-prismatic stereoscope is used, it can only be said that the eyes perform their usual miracle of combining images under conditions very far removed from those of nature, and yet producing a natural effect.

The critical examination of No. 3 leads to very different results. It is taken with lens separation of 2¼ in., which is ¼ in. more than the correct average separation of 2½ in. of the eyes when looking at a point 12 in. distant. The first effect of this is to increase the already violent natural perspective of the group, so that the mind is called upon to fit together a three-dimensional jig-saw puzzle with some of the pieces missing. The second result is that the image, properly viewed, is brought to a distance of only about 9½ in. from the eyes, or nearer than the distance at which the slide should be held. Corresponding points of the two prints should in this case not only coincide, but they should overlap in the other direction: the top end of the match in the right print should be ¼ in. *to the left* of the same point in the left print. The error in mounting here is therefore 2.9+.5 in., or a total of 3.4 in.! This outrageous departure from accuracy is such that not even the most complacent of cross-eyed stereoscopes can make any attempt to conceal it. Instead of the eyes converging upon points only some 9 in. distant, they are almost, or if a plain lens stereoscope is used, they are absolutely diverging. The whole delicate measuring apparatus of the eyes is thus thrown out of gear, and ceases to function. To ask the mind to pass judgment on what it sees under these conditions is like setting a man to tune a piano after we have filled his ears with wax.

The real obstacles to stereoscopic progress are the terrible facility with which the mind receives an impression of perspective relief, and the consequent inability to pass judgment on what is presented to it. For definite information as to size and distance it clutches at straws, or matches; and if it can resolve the components into a pleasing whole, it is content. Unless the stereoscopic observer can be taught to exercise his judgment with the same confidence as that with which he looks about him every day, the stereoscope must remain a useless and possibly a harmful toy. The precision and certainty of exact method in taking, mounting, and viewing must be substituted for the tedium and futility of haphazard, partial experiment. And the true method, when once adopted, will be found infinitely easier and less laborious by those who put it into practice.

H. C. Browne.

THE NO-DAYLIGHT CARBRO PROCESS.

The technical side of the "Carbro" process has already been described in this Journal, and full formulæ and working directions are obtainable from the Autotype Company. But it may be of interest to put forward the results of some recent tests, and to discuss the utility of the process to the professional.

There is one point which must be driven home at the outset, and that is, that a Carbro print is actually a carbon print: not a "semi-carbon" or a "carbon-effect," but the real thing, which means that it allows of far greater range of colour, base, and general effect than any other process or combination of processes.

The one and only essential difference in the making of a Carbro and of a regular carbon is the method of impressing the latent image. In the newer process daylight is dispensed with, and exactly the same effect is produced by squeegeeing the carbon tissue into contact with a bromide print in the presence of certain chemical solutions. From the point at which the tissue is stripped from the bromide print the two processes are the same, with the exception that, when using Carbro, there is no reversal, right for left, when using the single transfer process, and that the more roundabout double transfer is therefore unnecessary.

This method of "printing," if one may use the expression, has an important advantage, over and above that of the elimination of daylight. As any carbon printer knows, the one stumbling-block in the old process was uneven printing. Unless, indeed, nothing else was done, it was most difficult to make a set of, say, a dozen carbon prints of exactly the same printing depth. There were at least three possible sources of error:—the Actinometer paper might vary, the tissue might be "stale," and there was always continued action after removal from the frame.

Now with Carbro these troubles do not exist. The strength and duration of immersion in the sensitising baths can be controlled, also the depth of the bromide print and the time of contact therewith, which are the factors affecting the printing. As a matter of routine, development will almost always take place at practically the same time after "stripping," so that continued action is unlikely to cause unevenness; as a matter of fact, my own experiments point to the fact that, if continued action is not entirely absent, it is, at any rate, greatly reduced.

Let us now examine the process from the point of view of the man who, seeing its advantages, wonders if it is a practicable workshop printing method.

Those to whom speed is the great requisite are not likely to desert bromides, but the man who feels that he wants something better, and yet must be able to rely on sending his prints out within a reasonable time, has every reason to give Carbro a fair trial. That it will more than fulfil his expectations I do not doubt.

The elimination of daylight printing means that the process becomes independent of weather conditions. In other words, you can absolutely rely on your output being regular. It does not mean that Carbro is a speed process—it cannot compare with bromide for this—but the average studio of the better class will not mind a comparatively slow output, providing it is a regular one. As a general rule, I suppose one bromide print will be used for each order of, say, half a dozen "Carbros," but in cases of emergency it would be easy enough to make half a dozen bromides and take all the Carbros through at one time. If a single bromide is to be used, it will be found that some two hours will be necessary between stripping one Carbro from it and squeegeeing the next.

I have not made more than six Carbros from any one bromide, and have not been troubled with blisters or any other mechanical defect in the original print. It does not seem very advisable to harden the print to any great extent, as this has, in some cases at least, a detrimental effect. But the drying of the bromide print, before use, will harden it quite sufficiently and at the same time have no ill effects. Should this be done, it can hardly be necessary to point out how very essential a thorough soaking of the print is before any attempt is made to squeegee it.

There does not seem to be any "best" paper, but "platino matt" certainly works with greater ease than any other surface. This is due, in part, to the ease with which it may be squeegeed, and possibly also to the fact that, having no "surface," it is more easily permeated by the solutions. It is most advisable that the same paper should be used in all Carbro work, because, as one would expect, different papers work at different speeds, and the fewer variable qualities the better, especially when a test is being carried out.

The type of print may vary within pretty wide limits, but for the ideal result the bromide should be a shade lighter than for normal use. Carbro reproduces to a remarkable degree the slight—almost invisible—tones in the high-lights, and anything like an over-printed bromide is liable to lead to "bunged up" lights in the Carbro. The scale of the negative used and of the bromide print may be met by variations in the working, which makes the process of unusual value in the case of uneven negatives.

For fancy vignetting, double printing, and faking in general, Carbro seems perfectly well adapted; it should be of great use in those often troublesome cases where, perhaps, five or six negatives have to be vignetted on to one sheet of paper. Also, if landscape work is done, the insertion of clouds is much more easily done with "Carbro" than with any other type of print whatever.

There is a use, one might suggest, for "Carbro" which may add considerably to its value—that is, in the reproduction of prints, instead of copying. Naturally, this would only be done with your clients' approval, as it involves bleaching and re-developing the print. But the results should be far and away better than any copy, and the risk of damage to the print really very slight.

One thing is certain in the future of "Carbro"—that it will become the normal means of obtaining high-class enlargements. The cost of enlarged negatives has driven many to bromide enlargement who fully realised their faults. Now it is simply a matter of making an ordinary bromide enlargement and taking any number of Carbros from that. The quality of the process is shown even better in large work, and the difference between the best of bromides and a Carbro is greater than most people think. Also, your finishing staff will bless you when you take to Carbro; there is no easier paper than this to work on. To sum up. My tests have led me to the conclusion that the professional who wants the very best results, and yet cannot undertake daylight printing, will find in Carbro the solution of his difficulties.

ARTHUR G. WILLIS.

PHOTOGRAPHS OF LLOYD'S.—Messrs. J. H. Dallmeyer, Ltd., of Carlton House, 11d, Regent Street, Piccadilly Circus, S.W.1, advise us that the film recently taken at Lloyd's by "Around the Town Film Co., Ltd.," showing the underwriters' room, was taken with one of their new *f*/2.9 1½-in. Pentac anastigmat lenses, the enormous speed of this lens enabling a well-exposed film to be obtained without the use of artificial light.

A X-RAY HOWLER.—Among the latest schoolboy howlers, published in an educational monthly, is the following: "X-ray photographs are those taken when the sun's rays cross each other."

DEATH OF PROFESSOR GABRIEL LIPPMANN.

The death was announced last week of the famous French physicist, Professor Lippmann, during his return from America, on board the steamer, "France," at the age of 76

In photography M. Lippmann was known chiefly in connection with the process of colour photography, which bears his name, although this latter is a small part of his many contributions to experimental physics, in particular, electricity. He was born in Luxemburg in 1845, of French parents, and after a distinguished career in classics, philosophy, mathematics, and physics at the Ecole Normale, became a student in Heidelberg University, under Kühne and Kirchhoff. Germany at that time offered opportunities of study to an investigating mind which were not available in France, where education in science still followed the strict channels laid down by Napoleon. Returning to France, Lippmann, who had now chosen electricity as his subject, continued his researches at the Sorbonne, under Jamin, and a few years later was appointed director of research in physics at the Sorbonne. The rest of his life was spent in scientific research, of which he was one of the pioneers in France, and witnessed the carrying out of numerous investigations in heat, electricity, and other branches of physics.

His process of colour photography was, so to speak, the offspring of his theory and practical experiment. In 1886, whilst teaching optics at the Sorbonne, he conceived the idea of demonstrating the formation of "stationary" or "standing" waves of light, that is, waves which have "interfered" by reflection back on to the original path, by making records of colours. Some years passed before he succeeded in preparing the grainless transparent emulsion required for this process, but in 1891 M. Lippmann made known his discovery, which aroused an extraordinary degree of interest. Scientific men admired it as a most exquisite physical demonstration; photographers, somewhat precipitately, saw in it the basis of an ideally simple process of colour photography. Time has shown that the view of the former was the more correct, for, despite the labours of many photographic investigators, the making of a Lippmann colour photograph remains more an optical experiment than a working process of colour photography. The special emulsion required for it was improved by M. M. Lumière and others, including Mr. Edgar Senior in this country, and, so far as the photographic technique is concerned Mr. Senior's methods, published in the manual of colour photography by Bolas, Tallent, and Senior, have done all that is possible to bring the process within the capacity of photographers. The characteristic qualities of the results have, however, prevented it from becoming popular.

FORTHCOMING EXHIBITIONS.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary. J. R. Lawson, 2, Gould Street, Toronto, Canada.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1,

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary. W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

LUXURY EVIDENCE.—The smoking of Turkish cigarettes, the creasing of trouser legs, and the carrying of a camera were items given as evidence of means in a London County Court last week.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

A Dark Slide Hint.

OLD dark slides which are inclined to come open at inopportune moments may be cured by drilling a small hole through the top of each side-clip and inserting a cheese-headed screw in the woodwork underneath the hole. This forms a very efficient catch.—A. W. W.

Fine Focussing Screens.

METHODS of fitting up temporary or make-shift focussing screens are as plentiful as labour troubles, and all kinds of dodges are to be found in most reference books. I have, however, never seen the following plan advocated. It was given to me by an American tripper, who discovered me trying to focus on a damped handkerchief stretched on the frame from which the ground glass had disappeared. Take about 120 grs. (¼ oz.) of common glue or gelatine, soak it for an hour or two in 1 oz. of water, then dissolve by heat, and add to it ½ oz. of boiled milk. This when coated upon plain glass gives a screen of extraordinary fineness, which is an ideal medium on which to focus, particularly dark interiors. The opacity of the screen—or rather its translucency—may be regulated by adding more or less milk; the quantity given, however, produces what I believe to be the best screen. I have tried mixing milk with the gelatine mountant used in some workrooms, but the milk does not seem to mix so well with the mountant as with a plain solution of glue, or gelatine, perhaps because of the inclusion of methylated spirit in the mountant.—L. T. W.

Removing Ink Stains from Negatives and Prints.

IT is not often that a negative or print is damaged by ink, but accidents will happen, and when they do it is very useful to know a good remedy for the mischief. Photographs are liable to this kind of accident when handled at the desk where ink is in constant use, while violet ink, as used for typing and copying, may get about on fingers and papers in a most annoying way. Post cards are very often deliberately inked with autographs, and in copying it is often desirable to remove the writing. A quick solvent is sulphuric acid. It should not be used stronger than one part in four of water, and if diluted from a concentrated fluid great care should be taken to pour the acid into the water and not *vice-versa*. At the strength of one in five, the acid is safe to fingers and photographs and will remove ink without injury to gelatine or silver. There is no need to prepare a dishful, a spot or two applied with a small brush should be sufficient. A short wash afterwards is necessary.—THERMIT.

Toning Ordinary P.O.P.

SELF-TONING papers have their advantages, it is true, and makers of such issue instructions by which a greater range of tones is obtainable, but in my opinion the charm of the process of self-toning goes if the supplementary baths called for are used. In spite of the great popularity of self-toning there are many assistants who, like myself, have a liking for ordinary P.O.P., but who meet with difficulties when toning it, and these unfortunate workers cannot do better than try a simplified method of toning once advocated by Mr. G. Watmough Webster. I have used this system with the greatest success during the past eight years, and can recommend it. The process consists merely in adding ordinary kitchen salt—not the refined table variety—to the ordinary gold and sulphocyanide toning solution in the proportion of about 60 grains of salt to the pint of toning solution. When the salt is thoroughly dissolved the P.O.P. prints are placed without any washing at all into the solution. No milkiness will be seen, and toning proceeds in the ordinary way. When the proper tone is reached the prints, again without any washing, are placed direct into the hypo bath. When finished the prints are—if all goes well—in every way equal to those dealt with in the accustomed way, and if any difference is noticeable at all it is in favour of the non-washing method. The exact amount of table salt added is not a material matter; whether 40 grains or 80 grains are added the result is practically the same, and any initial difference in colour caused by the salt is quickly lost when

the toning proceeds. As to permanency, there is, I believe, nothing to support the probability of ultimate fading, and I have before me prints several years old, which are now as fresh and pure as on the day they were made. A word of caution is necessary as to fixing, as the usual strength of hypo is far too strong. A 10 per cent. strength is the best to use,andthe time of immersion, so long as the prints are kept in constant motion and not allowed to remain in contact for any but the briefest time, should not exceed ten minutes. The simplicity of this little-known process, combined with the enormous saving of time, should do much to increase the use of P.O.P. That few, if any, bromide developed printa can equal the results obtained on printing-out papers will be readily admitted, and although the self-toning papers on the market have proved themselves to be eminently successful, yet the range of tones possible in these does not approach that obtainable by a gold-toned P.O.P. And, what is most important, there is a very large section of the public that asks for, and likes best, the ordinary P.O.P., with its "real photographic" colour.—G. WILSON.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 4 to 9.

CINEMATOGRAPHY.—No. 18,523. Producing animated cartoon films. D. Barker.

RECOVERING RESIDUES.—No. 18,090. Treatment of waste cinematographic films, etc., for recovery of silver and gelatine. D. B. Macdonald.

DRYING PRINTS.—No. 18,387. Oven for drying photo prints, etc B. H. Rowe and Rowe and Elliott.

DEVELOPING AND FIXING.—No. 18,186. Apparatus for developing and fixing cartridge photographic films. R. Rycott.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AERIAL PHOTOGRAPHY.—No. 159,310 (November 24, 1919).—The object of the invention is to produce negatives which overcome the difficulty and avoid the loss of time which has occurred in

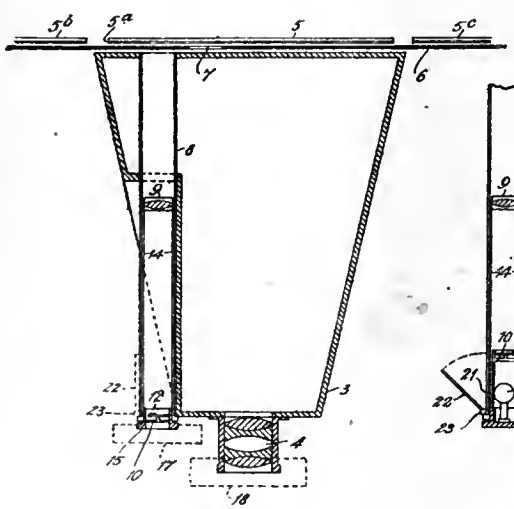

Fig. 1.

Fig. 2.

the effort to locate an indication of points of the compass on topographic photographs produced by aerial photography.

In the drawings 1 is part of a negative or print containing an indication 2, produced by my attachment, which is fitted to a camera 3, having any suitable lens 4. Any suitable photographic plate as 5 or the like is used having a sensitive film 5a. It is shown in a position to receive the ordinary exposure, its earlier and later positions being in some forms of magazine camera as shown at 5b and 5c respectively.

A casing 8, shown as tubular, is attached to the camera at any convenient part and is made of convenient size and form. This casing contains a suitable lens or lenses 9 and an indicator 10, details of which appear in figs. 4, 5 or 6.

The casing and its attachments form portions of a second camera, but with its parts located to allow of its use in co-operation with the main camera. In figs. 4 to 6, part 10 is a disc or fitting, its face 11 being adapted to act as a background or wall, and it may be arranged as a compass dial. On this face 12 represents the compass needle which is pivotally mounted to swing on the disc 10 as usual; 12 is a luminous faced compass needle: 13 is a slot pointing in a predetermined direction as north and south, and located to one side of the compass needle; and 13 shows slots pointing in a predetermined direction as north and south. The latter slots extend along the compass needle, and will allow light to pass through the background. The light is to pass through the slot or slots for indicating what is required on the photographic plate.

The light has somewhat the same reault as is secured when stencilling except that it acts by focussing the indicator through the lens 9, but for brevity the slotted members may be termed camera stencil plates. The lens 9 is shown in a tube 14 and is independent of the camera view lens 4.

The compass device and lens thereof are monnted in such positions that the indicator image to be produced becomes projected

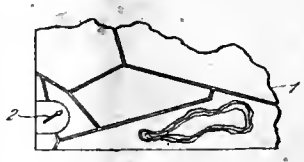

Fig. 3.

upon the sensitive plate when required, that is, when, or very nearly when, the exposure is made for the view to be photographed.

Tube 14 is removable from tube 8 and a removable fitting marked 15 can be used with its outer end open to daylight, carrying the compass indicator and is arranged as an attachment to tube 14.

Instead of shutter or blind 6 a shutter 17 may be nsed, which is independent of the view lena, which may also have a shutter 18, these shutters, being shown in dotted lines in fig. 1, but instead of the separate shutters there may be one outside shutter arranged to make by its action exposures for photographing through both lenses.

In fig. 1 daylight is supposed to be used, hence the background allows no light into the camero except where it passes through the slot as in fig. 4 or 6. In a modification of fig. 1, however, if the background be that of fig. 5, the light is kept out completely, but the needle 12a or indicator ia luminoua.

When artificial light is used, such as from a lamp 19 (fig. 2)

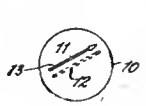

Fig. 4.

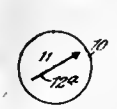

Fig. 5.

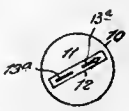

Fig. 6.

the latter is suitably attached as to a fitting 20 of the tube 14, this outer part of the fitting closing this tube light-tight. The fitting 20 is removable and replaceable at will. The use of a flash light or lamp renders a shutter as 17 (though atill usable) unnecessary.

A ruby window 21 may be provided in the lamp carrying attachment for indication of the lamp action to an observer, and a reflector 22 may be provided to reflect the flash light to the operator. This reflector may be hinged at 23 to close against the window at will, and may be fastened in closed position or held closed by spring means. Indicators prepared in advance may be at hand and be inserted or removed at will according to the photographer's requirements.—Thomas Edward Moorhouss, 79, Kooyong Koot Road, Hawthorn, Victoria, Australia.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

N. G. (DEVICE).—No. 412,035. Philosophical instruments, scientific instruments, and apparatus for useful purposes; instruments and apparatus for teaching. Nitsche and Günther Optische Werke, 4-5, Dunckerstrasse, Rathenow, Germany, manufacturers of scientific and optical instruments. January 29, 1921.

New Books.

DICTIONARY OF BRITISH SCIENTIFIC INSTRUMENTS.—This is a publication of the British Optical Instrument Manufacturers' Association, and serves the commercially useful purpose of giving a brief popular description of all kinds of scientific instruments, not only optical, but electrical, and also those for measurements of all descriptions. In addition, one or more index numbers are appended to entries in the dictionary relating to commercial apparatus and inform the consultant as to the British firm or firms from whom the apparatus can be obtained. A large number of pages is occupied by drawings of instruments, a feature which will be of great usefulness to the foreign buyer as a means of elucidating the text, which, of course, is in English. The volume is published by the Association at 2-3 Duke Street, St. James's, S.W.1, price 21*s*.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, JULY 24.

South London Photographic Society. Excursion to Langley Farm, Beckenham.

TUESDAY, JULY 26.

Hackney Photographic Society. "Portraiture." G. White.

THURSDAY, JULY 28.

Hammersmith (Hampshire House) P.S. "The Print." F. Bowen Williams.

SATURDAY, JULY 30.

Hammersmith (Hampshire House) P.S. Week-end. July 30, 31-August 1. Lewes.

Manchester Amateur Photographic Society. Ramble from Bramhall to Prestbury (via Swineseye).

CROYDON CAMERA CLUB.

Last week Mr. N. Ching gave the first of two demonstrations on "Dental Dentures." Without knowing the exact programme, many had heard that dentistry was to be dealt with, and gleefully anticipated a Croydon Grand Guignol and tense molar movements, with some heroic member taking the place of the versatile Miss Sybil Thorndike, the extraction of teeth being substituted for, say, the prising out of eyes, to take an optical incident from one of the charming nightmares at the Little Theatre.

Sad to relate, the demonstration provided nothing sufficiently startling to remove the languor induced by the hot-stuff weather, though it proved to be a very able exposition on the assembling and fitting of false teeth. Much specialised knowledge was imparted, and the usual vote of thanks was carried with much acclamation.

The previous week Dr. Mees was entrapped into another lecture, one of a series of papers delivered in the U.S.A. A title first selected, "The Importance of Scientific Research," he said, made but little general appeal, but when the "Road to Wealth" was substituted, it drew like smoke.

The main theme is well indicated by both titles in conjunction, and an unanswerable case was made out for the furtherance of research laboratories. In his opinion, any nation economising in industrial and scientific research is bound to fall behind other countries, for wealth invariably follows knowledge. In the States, laboratories on the most extensive scale, and operating at enormous expense, have been found to pay, and to pay well, the vast corporations running them.

Particularly interesting, too, were many illustrations showing how purely scientific investigations, with apparently not the remotest connection with anything practical, have directly paved the way to commercial developments of the utmost value. Nor should be forgotten the wonderful advances of medical science, which from knowledge acquired now conquers many a lethal disease. Suppose, said Dr. Mees, this country was invaded by a plague of pneumonia, all would be scared, for knowledge how to combat it would be wanting. On the other hand, if bubonic plague were to enter, few would be apprehensive, for it is known it is communicated to man by fleas from infected rats. Therefore, destroy the rats and dodge the fleas, and the peril vanishes. The correct procedure for dodging the fleas was not described, but obviously must postulate a fair degree of agility.

Many other considerations of great interest entered into the paper, which was accorded a hearty vote of thanks.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, on Friday, July 8, 1921. There were present Messrs. Marcus Adams, A. B. Basil, A. Bennett, Frank Brown, Gordon Chase, Tom Chidley, Alexander Corbett, C. F. Dickinson, Alfred Ellis, George Hana, W. Illingworth, T. C. Turner, and F. G. Wakefield, with Mr. Lang Sims (secretary).

Mr. Alfred Ellis took the chair.

Apologies for absence were read from Mr. Swan Watson (president), and from Messrs. Chapman, Haines, Lambert, Read, Spink, and Wheeler.

The Secretary said that a letter had been sent on to him by the secretary of the Royal Photographic Society, stating that the photographers of Vancouver desired to obtain for their Congress a few examples of work from leading photographers of London. He (the secretary) had seen the Commissioner of the Commercial Intelligence Branch in London, who had interested himself greatly in the matter. Mr. Marcus Adams, secretary of the Exhibition Committee, to whom the matter had been referred, reported that he had sent to Vancouver over thirty exhibits representing British work.

The Professional Photographers' Association in South Africa (Cape Section) had written asking whether the Council in London would accept exhibits from South Africa for their next exhibition. The letter which the secretary had written in reply, conveying cordial sentiments, and stating that the Council would display such photographs so far as their restricted space would allow, was endorsed by the Council, and the correspondence was handed over to Mr. Marcus Adams to be dealt with further.

Mr. Marcus Adams reported that Mr. Reginald Haines, a member of the Council, was visiting the United States, where he would attend the American Congress of Professional Photographers. The Council could not be consulted before he went, and he wished to know whether he could be authorised to convey to the Congress the good wishes of the Council of the Association in England, and to present a British flag in the name of British photographers.

It was agreed that the secretary should draft a letter which, with the approval of the chairman of the Council, would be sent on to Mr. Haines in New York, authorising him to convey the hearty good wishes of his colleagues to the photographers in the States, and that the flag which Mr. Haines had already taken with him should be presented in the name of the Association.

Mr. Frank Brown read a letter which he had received from Mr. Pirie Macdonald, and on the motion of Mr. T. C. Turner, who said that anything which assisted Anglo-American friendship was most welcome, it was agreed that the essential portion of the letter should be recorded in the minutes, viz.:—

"I am not going to Edinburgh, though I was chairman of the Onto Edinburgh Committee, and was booked to sail, and had my passage bought, but business here does not easily permit our getting away before the first of July, and something has occurred which makes it impossible for me to afford the time at that season this particular year. Of course, I am hugely disappointed, but what is, is. I have wanted for many years to attend one of your British conventions, but the same difficulty obtains. If they were only held in July I am sure that you would always have one or two of us over, and I cannot help feeling that it would be worth

while considering the change of date, because we *must* get the British and Americans closer together. If they only were to know one another better we could between us maintain the peace of the world. You would find Americans very likeable if you were to see enough of them. Of course, they are different, but they are very real. I am glad to find that you were interested in my talk on the code, and I am glad to be able to assure you that there are many, very many, Americans who live pretty close to the rule. It is not an inoperative and theoretical thing.

"I am glad to have got your letter, and I hope that we may meet some day.—Most cordially yours,

"PIRIE MACDONALD."

The Secretary reported that the Finance Committee met on June 17 and recommended payments to the amount of £67 10s. The recommendation was approved.

The following names of new members were read and approved :—Lena Gertrude Horsfield, Maltby; Rose Anna Carter, Romford; George William Pilkington, Annisland, Glasgow.

The Chairman reported that since the last meeting he had received a letter from the solicitor, Mr. Reginald Vaughan, and in consequence spent an afternoon with him, getting into final shape the Articles as amended at the last meeting. The Memorandum was now with the Board of Trade, and, so far, no reply had been received There the matter must remain until the next Council meeting.

Mr. Frank Brown proposed that the Council adjourn as usual for the summer recess and meet again on the second Friday in October, and this was agreed to.

Mr. Ellis having to leave the meeting at this point, Mr. Frank Brown (past-president) took the chair.

Mr. Marcus Adams reported that he had sent a collection of pictures, twenty-five in all, from those which had been selected by the jury for the Congress Exhibition, to Ohio, following upon a request from that quarter, and also, in addition to the Vancouver consignment, he had in hand a collection of pictures for the Copenhagen Congress, and these, as soon as they were returned, he would forward to South Africa. Next year he hoped that there might be a foreign section at the Exhibition. For these outside exhibition purposes, he would be glad to have, in addition to the pictures available from the annual Exhibition, others which any member of the Council or of the Association could furnish. The selecting committee was still in existence, and he would always bring any question of selection before it.

The Deputy-Chairman thought that the works chosen for dispatch abroad should be limited in the first instance to those which had been exhibited at the Association's Exhibition, but it was agreed to leave this and cognate matters to the Selection Committee.

Mr. Basil suggested the appointment of a permanent Selection Committee instead of the temporary one for the Congress-exhibition purpose.

Mr. Hana proposed that a committee be appointed to form a collection of representative work of the P.P.A., which collection was to be drawn upon for all exhibitions at which P.P.A. work might find space, and that the committee should be given a free hand to send what they liked, as many as they liked, and as often as they liked. Mr. Corbett seconded, and this was agreed. The committee was appointed as follows :—Messrs. Adams, Basil, Corbett, and Speaight.

Mr. Illingworth proposed that the committee should not send out anything without the sanction of the Council, but on some of the difficulties of the situation being pointed out—i.e., requests at short notice—he withdrew the proposition.

A further motion was agreed to, on the proposition of Mr. Gordon Chase, approving of the prompt action which Mr. Adams had taken, and thanking him for it.

The question was raised of a Professional Section in connection with the Salon and the Royal Photographic Society's Exhibition. This matter was not pressed, but it was agreed that individual members should be urged as far as possible to contribute to representative photographic exhibitions.

The question of the choice of a Press Agency which could be recommended to members of the Association who desired to know of a zealous and dependable firm to whom they could entrust their work was again mentioned by Mr. Tom Chidley.

Mr. Corbett proposed that a number of names be set out by the Association to be recommended as respectable and straightforward firms from which members could select. This was agreed to.

The Secretary read an extract from "John Bull" respecting what was alleged to be an enlargement fraud, and detailed the inquiries which he was making in endeavouring to follow up the complaint.

Correspondence was also read concerning a dispute with regard to reproduction fees, and it was agreed that the correspondent should be advised to stand by what he had originally written. Another member asked for advice on a small dispute as to the terms of an advertising contract which it was claimed he had not fulfilled, and it was resolved to seek the advice of the solicitor. Another member wrote for advice on the old question of payment for proofs, and it was left to the secretary's discretion to frame an answer, Mr. T. C. Turner urging that many of these troubles could be avoided if every photographer was explicit in making his contracts.

PROPAGANDA.

It was suggested that members of the Association should be provided with a card or certificate similar to that of members of the P.P.A. in America, with the date stamped across it to prevent improper use. Mr. Hana moved that a committee be formed to consider this question and other questions concerned with propaganda and publicity. Mr. Gordon Chase seconded, but ultimately it was agreed, on an amendment by Mr. Alexander Corbett, seconded by Mr. W. Illingworth, that this matter should be put on the agenda for the next Council meeting. Mr. T. C. Turner said that he would not like it to be thought that the Association was behind the times in any particular. At no time in its history had it enjoyed more largely the confidence, at all events, of photographers.

After a sitting of three and a half hours the Council stood adjourned.

News and Notes.

PHOTOGRAPHS AS LEGAL EVIDENCE.—During the hearing of a claim for possession of a house at Wandsworth County Court last Friday, for which an alternative house was offered, Judge Harington said that in these cases judges would be very much assisted if the parties concerned were to produce a photograph of the house for which possession was sought, and also one of the house offered as alternative accommodation. He stated that he could not go and look at every house, and the photographs would be of material assistance, but such pictures were seldom seen in court.

THE CENSORSHIP OF FILMS.—A County Council has no power to limit the licence for cinematograph films to those which had the certificate of the British Board of Film Censors. This was the unanimous decision last week of a King's Bench Divisional Court, composed of the Lord Chief Justice and Justices Avory and Sankey. During the hearing of a case, the Lord Chief Justice asked: Who are the British Board of Film Censors? Are they a statutory body? He was then told that they were a body established by the trade themselves to prevent undesirable films being exhibited. It was also stated that the Act provided for examination by a committee of justices, inspectors, and police The British Board of Film Censors was a body quite unknown in law, and there was no remedy against them.

DACTYLOGRAPHS BY WIRE.—We understand that a journal dealing with dactylography has been started. Dactylography (from the Greek *daktulos*, a finger) is the science of identification by finger-prints, and in the first number of the new journal Mr. Henry Faulds claims to have made the first suggestion that photographs of finger-prints should be telegraphed, he voicing the matter as far back as 1905, and again in 1912. "Nine years after these words were published," writes Mr. Faulds, "this feat has been successfully accomplished. M. Belin, the inventor of the photo-electric apparatus, now called after him the Belinograph, has adapted it for the identification of distant suspects by the transmission of finger-prints." Two impressions were sent from Paris, and Professor Ottolenghie, head of the detective college at Rome, who was present at the demonstration, expressed himself as quite satisfied, and intends to apply it practically in criminal cases. Mr. Faulds, it may be mentioned, is a leading authority on the science of finger-prints, and an article by him on the subject appeared in "Nature" as early as October, 1880.

Commercial & Legal Intelligence.

LEGAL NOTICE.—Notice is given of the dissolution, by mutual consent, of the partnership between Ernest Grattan Phillipse and Ernest Harold Lees, carrying on business as photographers and fine art publishers at 46, High Street, and 12, The Promenade, Ilfracombe, Devon, under the style of Phillipse and Lees. All debts due to or owing by the late firm will be received and paid by Ernest Grattan Phillipse, who will continue to carry on the business.

A MEMORIAL TO FOX TALBOT.

To the Editors.

Gentlemen,—It is now 44 years since the death of Henry Fox Talbot, upon whose researches the present-day practice of photography and of photo-engraving has been built up.

At the recently-held Photographic Convention at Bristol, an opportunity was taken by his grand daughter, Miss M. Talbot, to present his collection of experimental apparatus and results to the Museum of the Royal Photographic Society. So far no steps have been taken by British photographers to perpetuate the memory of their distinguished fellow-countryman. To remedy this omission, the Council of the Royal Photographic Society has opened a fund by means of which some permanent memorial may be set up at Lacock, where his home was, and where his experiments and discoveries were made.

As President of the Royal Photographic Society, I appeal to all interested in photography in any way to take a share in remedying this omission by contributing to the fund. A half-crown subscription list is being opened by the Editor of "The Amateur Photographer and Photography," at 20, Tudor Street, London, E.C.4, to which all amateurs are invited to contribute. In addition donations, large or small, to the memorial will also be gratefully accepted and acknowledged by:—

(1) Mr. W. L. F. Wastell, Vice-President, Royal Photographic Society, 35, Russell Square, W.C.1.

(2) Mr. G. C. Weston, Chairman of the Affiliation of Photographic Societies, 22, Springwell Avenue, Harlesden Lane, N.W.

(3) Mr. Geo. E. Brown, Editor of "The British Journal of Photography," 24, Wellington Street, Strand, W.C.2.

(4) Mr. Arthur C. Brookes, Editor of "The Photographic Dealer," Sicilian Avenue, Southampton Row, London, W.C.2.

(5) Mr. Lang Sims, Secretary of the Professional Photographers' Association, 437, Brixton Road, London, S.W.2.—Yours faithfully,

GEO. H. RODMAN,
President of the Royal Photographic Society.

35, Russell Square, London, W.C.1. July 21, 1921.

DAMAGED LENSES.

To the Editors.

Gentlemen,—An editorial note on "Damaged Lenses," appearing in the issue of July 15, affords an opportunity for referring back to a similar note on "Rusted Lenses," published some months ago. In the previous note you warned readers against submitting atmospherically "rusted" or tarnished lenses to the process of re-polishing. In effect, you stated that it was better, or wiser, to leave the defect, though thereby the lens might be rendered less effective.

Acting on this warning, I refrained until quite recently from any attempt to submit a valued foreign anastigmat to treatment. Then, conscious of a certain rashness, I consulted a leading optical firm in London. Their definite opinion was that the "rust" could be completely and safely removed; also the scratches to which, I understand, the affected surface is particularly susceptible. I permitted them to "operate," and the result is completely successful, the lens being in all respects restored to its original brilliant working condition. I make this communication in the interests of others who may possess "rusted" lenses; also in the hope that a question of vital importance may be further discussed in your columns.—Yours faithfully.

LYULPH LUMLEY.

Hendon, N.W.2, July 12.

THE INVENTION OF SELF-TONING PAPER.

To the Editors.

Gentlemen,—Although not particularly interested in the question of who was the originator of self-toning paper, I read the communications of Mr. Wall and Mr. Debenham in your issues of April 8 and 15 last with some interest, being a user of large quantities of British made (I might say "home-made") self-toning papers.

Those interested in the history of papers should not, however, overlook a self-toning paper that was introduced a few weeks before I left my English home for the United States in April, 1886. This was Rivot's self toning albumen paper which toned without the use of gold. The prints were simply fixed in a hypo bath, washed and dried by heat, the tone depending upon the amount of heat applied. This method would, of course, be out of the question with many of the modern papers which are of gelatine, but I cannot help thinking that the modern dodge of ironing dried self-toning prints with a hot iron, when a richer tone is wanted, is a relic of the old Rivot days when heat really did play its part in toning.

The Rivot self-toning paper—made by A. Rivot and Co., of Willesden Green, London—probably never caught on, as I heard nothing of it after leaving England. Anyway, the fact of its appearance should interest many of your readers.

New York. J. K. BRYCE.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

A. P.—According to the manufacturers, D.50, made up according to the standard formula, has a factor of 5 for negatives of average contrast, one of 3 or 4 for soft negatives, and one of 6 or 7 for negatives of greater contrast.

E. B. C.—We are sorry we know of no reliable means of removing mould stains from a miniature in water colours. We think the best thing would be to send the miniature to the firm by whom it was painted for their opinion as to its restoration.

J. N.—If you use anhydrous sulphite instead of crystal sulphite you can use half the quantity of the former, that is to say, 5 grains of anhydrous equal 10 grains of crystals. In the case of carbonate of soda, 3¼ grains of anhydrous equal 10 grains of crystal.

A. M.—A half-plate reflex is certainly a very efficient camera for street scenes, views, etc., and enables work to be got through very quickly, but it is very bulky and heavy, and also, in many circumstances, it has a drawback owing to its conspicuous appearance. We still think that the tripod half-plate camera is the best for all-round purposes.

F. L.—We do not know of a collodion process that gives an amber image. We believe the collodio-albumen process was very slow to develop, and gave a light brown image. It is quite easy to print direct from a wet plate, as follows:—Slips of waterproof paper are folded in a V shape and clipped each end of negative, which should be varnished. The wet plate is well drained and laid on top, the paper preventing actual contact.

A. J.—The most reliable bleacher for clearing off the image around the subject is the iodine cyanide mixture, made up according to the formula in the "Almanac," or perhaps with addition of further water. Usually this reducer is applied simply with cotton wool. Of course you would block out as much of the negative as possible by means of a black paper mask, cut roughly a little larger to the outline of the subject which you require in the enlargement.

C. H S.—Offered, in the shape of prints first of all, in sets of six to the postcard publishers, you might dispose of a few negatives, though they are smaller than most postcard publishers like. As regards other outlet, the only thing we suggest is that you keep an eye on the general illustrated press and particularly on papers dealing with India, the names of which you can see in "Willing's Press Guide," issued by Messrs. Willing, 125, Strand, London, W.C.2, price 2s.

M. B.—The anastigmat differs from an R.R. or rapid symmetrical lens in giving sharper definition in the margins of the negative at a large aperture. This applies both to lenses of maximum aperture, f/4.5 or f/5.6, and so on, and also to wide-angles, the maximum apertures of which range from f/9 to f/16. On the other hand, the advantages of the anastigmat are pronounced only when it is used at the maximum aperture or with comparatively little stopping down. With stops such as f/22 or f/32 there is not a very great advantage.

P. S.—The causes of reversal in film negatives are not altogether understood, but a very common one is exposure of an under exposed film to an unsafe dark-room light. In this case the negative image which is first produced by the developer acts as a negative upon the emulsion underneath, and, so to speak, prints a positive on the latter, which, in the final negative, overpowers the negative impression. We think this is the most common cause, although we do not think it is the only one. But, generally speaking, the causes of these reversal and partial reversal effects are very obscure.

T. H.—We should think any of the plate makers would supply you with plates as large as 38 x 24, coated with lantern emulsion, that is to say, in a reasonable quantity. By the ordinary method of flowing on the warm emulsion on to a levelled plate it is not a matter of very great difficulty to coat plates of this size with emulsion that you make yourself, but naturally such large plates are a different proposition from half-plates or whole plates as regards obtaining evenness of coating and also uniform drying. So far as we know there is no mechanical method of obviating the acquirement of skill in hand-coating, and the accumulation of some experience in drying the coated plates.

P. F.—We are not surprised that you cannot get the kind of results you appear to want from the negatives you send. Most of them have the appearance of being both over-exposed and over-developed. That of the soldier, however, is plainly under-exposed and perhaps only a little over-developed. The one marked "A" on the envelope represents fairly well the type of negative for a decent soft enlargement, though this negative would be called rather flat and weak by people who like somewhat more vigour in enlargements. We should say you would do better by giving somewhat shorter exposures and using a pyro-soda developer, which tends to somewhat more pluck in the negative, but be careful that you don't over-develop.

F. B.—We doubt whether increasing length of the arcs will materially decrease exposure. Your reference to 25 amps. for running two 10-amp. lamps in series is not clear. We suggest you still further reduce your resistance and employ larger carbons. If longer arcs are, however, desired, the object should be to increase the voltage across them. We suggest trying the effect of putting the two lamps in parallel and cutting the resistance out gradually till 20 amps. is taken from the main. An ammeter should be placed in series with one main. It may then be found that the resistance will overheat. On the other hand, if the resistance be too high the lamps will not burn steadily. In the latter case this can be rectified by using smaller diameter carbons.

J. P.—Certainly a postcard or half-plate reflex is a very good thing for the job, the only drawback to it is that it is bulky and heavy and is rather conspicuous in use in streets. Still, if you must have a hand-camera for quick and certain work, it is by far the best type, so long as the subjects are such that you can work at a fairly large aperture. But for all-round purposes, except rapidity of working, a light field camera (with roller blind shutter), used on a tripod, is the best for views, groups, street scenes, etc. Slower in use, of course, but you can make certain of your view and can stop down if necessary, also give a time exposure when such is needed, and for commercial view cards this is the type of camera almost invariably employed, using a 9-inch lens or a 6-inch lens, the latter if you are working in rather confined quarters.

P. S. B.—From the appearance of the negatives, it looks as though the whitish deposit was due to scum of oxalate of lime deposited in the gelatine by mutual action of lime salts in the wash water and the oxalic acid. That is only a guess, but if yours is a very hard water supply it may be the cause. We are afraid there is no very certain means of removing the scum. About the best thing you can try is either 5 per cent. solution of citric acid, or a solution of potass citrate, say 5 per cent. strength, with a little citric acid added to it. There appears to be a good deal of the brown permanganate stain still left in the negatives. Although oxalic acid serves to remove this brown stain, we think a much better chemical for the purpose is bisulphite of soda, say the commercial bisulphite solution diluted with about ten times its bulk of water.

G. A. G.—(1) Apparently the prints were supplied to order at a price which, presumably, included the right of reproduction in the particular publication. In the case of those from your own negatives, it will depend entirely upon the particular form of words used by the Vicar in ordering whether you can now claim for the full amount. At any rate, you can claim for the supply of the prints, which have evidently been delivered in accordance with a definite order. (2) As regards the work of copying old prints and others out of books, the Vicar, as the person giving the order, had a right to reproduce these particular copies of non-copyright works, and therefore it is immaterial to you whether the publication appears or not. You should apply or sue for amount agreed upon. We think the above should be sufficient for your purpose, but if you are in any further doubt it would perhaps be best to obtain the advice of a lawyer, to whom you could show all the correspondence that has passed.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3195. Vol. LXVIII. FRIDAY, JULY 29, 1921. Price Fourpence.

Contents.

SUMMARY.

Mr. E. R. Bullock, in a communication from the Eastman Research Laboratory, describes the result of a comprehensive series of experiments on the effect of the various variable factors in the sulphide-toning process. His results emphasise the correctness of the "Almanac" formula for the bleach, and also the necessity of using ample quantity of sulphide solution in darkening the prints. (P. 447.)

In a leading article we bring into prominence the points of chief practical importance examined by Mr. Bullock. Although these latter consist almost entirely of methods which have been published in connection with sulphide toning, they usefully draw attention to the factors of chief importance in regular successful use of the bleach-and-sulphide method. (P. 442.)

In the two concluding chapters of his articles on press photography, Mr. W. Lancelot Vining deals with the advantages of the long focus lens for certain descriptions of subject, in particular, sporting events; and concludes with some hints and cautions on the drafting of titles of news photographs. (P. 443.)

The opportunities which exist for making press photographs (of an illustrative type) of topical interest are the subject of a paragraph on page 441.

Mr. W. Ermen, in a brief communication, records the results of measurements showing the metol-like character imparted to hydroquinone by use in conjunction with a safranine desensitiser. (P. 445.)

Dr. D'Arcy Power has given the formula for the amidol developer long used by him for all descriptions of work. (P. 446.)

A type of enlarging easel which is easily made is described and illustrated by "Thermit" on page 451

In a short article on page 446 Mr. W. Gard describes an outfit for electric illumination of the dark room in places where there is no public supply of electric current

While the photographer possesses the right to the custody of the negative, it does not seem that liability for the preservation of the negative is automatically attached to that right. (P. 442.)

The difficulties created in portraiture by the present fashion of jazz costumes are considered in a letter from a correspondent. (P. 455.)

An American correspondent gives some particulars of the pioneer in the United States in cinematography, C. Francis Jenkins, whose first demonstration of a moving picture was given in 1894. (P. 455.)

The addition of clouding or gradation to portrait negatives taken against black backgrounds can be easily done by methods outlined in a paragraph on p. 441.

The remarkable improvement obtainable in the mounting of a photograph by appropriate selection of mounting board and border tints is the subject of a paragraph on page 442.

EX CATHEDRA.

Worked-in Backgrounds. There is great scope for improvement in many portraits taken against black backgrounds, in the way of introducing some simple effect of light, to relieve a flat sunken-in appearance. This may easily be done by preparing the back of the negative with very fine matt varnish, or, what we prefer, a transparent varnish, *e.g.*, Billdup and stumping in with black lead such clouding or gradation as may be required. No especial skill is needed, as the thickness of the glass softens the work and prevents any appearance of patchiness. If matt varnish be used it is not advisable to scrape any away from the denser parts unless the negative is very harsh, as this proceeding always falsifies the original scale of tones. With a transparent varnish this does not arise, and it is, moreover, easier to see the effect of the working while it is in progress. With matt varnish it is necessary to inspect the film side from time to time, and this is troublesome. Besides clouds, more detailed backgrounds can be introduced by those possessing some knowledge of drawing, and the effect will then be similar to the Heliolette backgrounds which provide the same facility in commercial form for the benefit of those who cannot draw.

* * *

Free-Lance Press Work. A branch of Press photography which Mr. Vining, in the series of articles which come to an end this week, has passed over somewhat lightly, is that of the making of a topical Press photograph. It is a branch of interest to the many whose homes are in places where subjects for news photographs rarely occur. Such subjects may not present themselves ready-made, but materials for making them are available everywhere, needing only the journalistic sense to turn them to good advantage. By way of illustration we may quote on this point one of the many fertile suggestions in the lessons on Press photography of the Practical Correspondence College. The writer is showing how opportunities are made: When I was living in the country I read, one spring, an inch paragraph in the "Daily Mail" about the shortage of fruit that might result from the lack of bees to transfer the pollen from blossom to blossom in the orchard. "Some growers," the paragraph explained, "were attempting to fertilise the fruit buds by brushing the pollen from one blossom to another by hand, with a wad of cotton wool." It happened that some trees in my garden were just then glorious with drifts of pale pink blossom. I had no bees, but I had a picturesque old gardener who looked the part. A big hefty handful of cotton wool, an old ladder, and the old apple tree were the only props required to secure two dozen different pictures of the gardener seriously dabbing the wadding at the innocent bloom. I blazed away two boxes of plates, as I felt that I was on a good thing. . . . . All the London picture papers

printed one of my negatives. . . . . But, as I say, I was lucky in every respect, not forgetting the title:—"Man Doing Bees' Work." And under the title was a little description of about fifty words based upon the facts in the paragraph which gave me the idea for this picture. The title sold the prints, which were bright and sunny and pleasing. The artificial creation of photographs to illustrate a topic of the day is now a considerable part of Press photography. If a picture editor is offered photographs which bring a subject before people who would not read about it, he will use them, particularly if they are also of pictorial quality.

* * *

Multiple Mounts. Comparatively few professional photographers seem alive to the value of the multiple mount as an aid in emphasising the qualities of distinctive work. The commercial mount is often over-assertive in design and embellishment, though in its more refined form it has attained a very high standard of artistic excellence. Yet it is a fact, of which many photographers are aware, that the type of mount at their command is hardly suited to the particular pictures that they happen to be engaged upon, either by reason of its colour, size or shape. The solution of the difficulty in cases like these lies in the choice of a multiple mount of tints that completely harmonise with the picture. And it may be added in passing that many photographers are not alive to the widely-differing effect upon a print of two tints that appear closely similar, unless a comparison is made. At the present time white or light-toned mounts are in favour, and are decidedly superior to the drab, dull-looking browns and greys that did duty not so very long ago. Many photographers, especially in country districts, are surprisingly conservative in the selection of their mounts, and anything other than the commercial article is seldom seen. Recently, in a country photographer's window, we noticed an enlargement of really fine quality mounted upon a dark plate-sunk mount. Could that photographer have seen the same print mounted upon a light-toned mount with a narrow tint surround, he would hardly realise that the print was the same. Whatever may be the advantages of plate-sunk mounts they are certainly not the ideal settings for examples of fine portraiture, nor do they appeal to a discriminating taste.

* * *

Liability for Negatives. One of the things in the common law respecting the relations of the portrait photographer with his customer, which is by no means as clear as it might be, is the liability of the photographer to preserve negatives made in accordance with a sitter's order. While it is perfectly well established that the custody of those negatives is the photographer's right, it is on the other hand not so well established that the photographer thereby undertakes the liability to keep them for the sitter's use at any time when the latter may require them for the supply of prints. Cases in which this question has arisen are rare, and in ordinary practice are not very likely to arise, owing to the facility with which a duplicate negative may be made from a print in the sitter's possession. An exceptional instance came to our notice a year or two ago, in which untoned proofs from negatives taken thirteen years before were returned to a studio for delivery of the photographs. In the meantime, however, the studio had changed hands and the new proprietor had no knowledge of the existence of the negative, which presumably had been destroyed by the previous proprietor. In cases such as these common law is determined, in a measure, by common custom in the circumstances of the particular trade; and certainly it is not possible to say positively that it is the common custom among photographers to preserve all negatives for the use of sitters at any remote date. On the contrary, the usual relations between photographers and customers are contrary to this assumption, and in the absence of any case in the Courts, so far as our recollection goes, in the history of photography there is no reason for assuming that the photographer is under the liability of keeping each and every negative until, say, he has the customer's permission to destroy it.

THE EFFECTS OF VARIATION IN THE SULPHIDE-TONING PROCESS.

THE paper by Mr. E. R. Bullock, of the Eastman Research Laboratory, which appears on another page, brings together a volume of carefully-conducted experiments which is deserving of study by users of the process of sepia toning by bleaching in the customary mixture of ferricyanide and bromide and darkening or toning in a bath of sodium sulphide. With one or two exceptions it cannot be said, perhaps, that the paper discloses facts which were previously unknown, but it very usefully sets forth the effects of variations in the two parts—bleaching and darkening—of the process, and on that account renders a valuable service, particularly as regards the advantage or otherwise of modifying the standard practice. This is especially the case in reference to the use of the darkening sulphide bath, which, in our experience of many questions on the part of readers, is the chief factor in failure to obtain satisfactory sepia prints.

Mr. Bullock takes as the standard process for sulphide toning the formulæ which have appeared for some years past in the "British Journal Almanac" (page 461 of the current volume). These formulæ were the result of, chiefly, the very thorough experimental work carried out by the late Douglas Carnegie. They differ to some extent from formulæ recommended by makers of printing papers, chiefly as regards the smaller proportion of bromide to ferricyanide in the bleach. The composition of the bleach in this respect is one of the first points examined by Mr. Bullock, who shows that there is no advantage as regards either speed of bleaching or colour of prints in increasing the ammonium bromide beyond the proportion (one-third of the ferricyanide) of the "Almanac" formula. Adopting this 1:3 ratio of ferricyanide to bromide it is shown what is the effect of greater or less strength of the bleach bath. At a strength of 10 per cent. ferricyanide, bleaching is rapid, but the colour is somewhat more yellowish. At from 3 per cent. to 1 per cent. strength the bleaching is almost as quick, whilst the colour is normal. At strengths substantially less than 1 per cent. of ferricyanide, bleaching is much slower, whilst the colour is just as good. It therefore appears that the most advisable strength is about 3 per cent., that is to say, 240 grs. of ferricyanide (and 80 grs. ammonium bromide) in 20 ozs. of water. This, it will be seen, is not much less than that of the "Almanac" formula.

As regards variation of the chemicals in the bleach, it is shown that there is no advantage in modifying the standard ferricyanide-bromide formula. Ferricyanide alone or in conjunction with potass chloride or iodide gives a bleach which is slower than the standard; and the colour of the prints, particularly when iodide is used, are more yellowish. Mr. Bullock records the effect of replacing the bromide by other salts, such as sulpho-

cyanide, selenocyanide, and cobalticyanide, without finding any advantage and, in fact, disclosing, in some cases, great disadvantages.

When we come to the behaviour of the sulphide darkening bath the observations recorded in the paper fully confirm the advice which is commonly given for the avoidance of inferior results in sulphide toning. It is shown that up to a strength of about .5 per cent. of sulphide in the darkening bath, the action is slow and the results are yellowish. On the other hand, increasing strength beyond about 1 per cent. of sulphide produces no increase of speed in darkening and no advantage as regards colour. While not mentioned by Mr. Bullock, it is worth emphasising that too strong a sulphide solution favours the blistering of many papers. At the same time it is important that the sulphide bath should not fall below strength in use, on which account the "Almanac" formula for the working solution directs a strength of about 3 per cent. Even so, the bath should be plentifully used in order not to exhaust it by the passage of many prints through it. Such weakening of the bath is particularly harmful if hypo is present in it. Mr. Bullock dismisses the idea that hypo is formed by oxidation of sulphide in the darkening bath, and assumes, we suppose, that it comes there through insufficient washing of prints. At any rate, its effect is a very marked one as regards yellowing of the colour.

A recommendation, which we think is new in respect to sulphide toning, is to dip the prints for about 10 seconds in a 1 per cent. solution of soda carbonate immediately before darkening in the sulphide. With most gaslight papers this is found to favour a more purplish colour. This effect is found to be produced also if a bleach, such as ferricyanide and chloride—that is to say, one giving a bleached image of silver chloride—is employed instead of the customary ferricyanide-bromide.

Some experiments on the bleaching of prints to images of silver ferricyanide and silver ferrocyanide are described but appear not to have resulted in any sufficiently-marked advantage over the standard practice; in fact, the results appear to be more yellowish, which usually is precisely the effect which is not wanted. Experimenters, however, will be interested in the bleach formulæ for ferrocyanide and ferricyanide images given in connection with experiments B. 11 of Table II.

Perhaps the most valuable certificate of the process is contained in Table III. of Mr. Bullock's paper, where it is shown what very little difference is produced in the final tone by very considerable modifications of the procedure. That is certainly one of the chief merits of the sulphide-toning process, one which makes it exceedingly difficult to find a more satisfactory process for the sepia toning of development prints. Very considerable alterations as regards time and temperature of bleaching, time and temperature of darkening and duration of washing at various stages have practically no effect upon the final result. The things which do have an effect, and which therefore call for the particular attention of the user of the process, are those to which attention has been specially called in the previous paragraphs of this article. A study of these considerations, in reference to the very clearly tabulated experiments in Mr. Bullock's paper, should therefore serve for the discovery of the cause of any difficulties experienced in the process.

PHOTOGRAPHY FOR THE NEWSPAPERS.

[Below we conclude the publication of the series of eight chapters on the supply of photographs to the newspapers written by Mr. W. Lancelot Vining, until recently art editor of the "Sunday Pictorial." So far as we know this is the first occasion on which the subject has been dealt with by a writer intimately acquainted with the production of an illustrated newspaper, and considering the matter from the angle of the art editor. Mr. Vining, who has spent his life in press photography, first as a free-lance and subsequently as a press photographer on the "Daily Graphic" and "Daily Mirror," deals here with the use of the long-focus lens in press work, and gives some final miscellaneous hints.—Eds. "B.J."]

VII.—THE LONG-FOCUS LENS.

Very few photographic correspondents do any long-focus work, which I think is a mistake. Nearly all staff photographers carry a long-focus lens, especially when on a big news story. I have in my mind a big railway accident of some years ago. The order went out that no cameras were to be allowed near the wreck. Only one of the photographers had a long-focus lens, and he literally wiped the floor with his rivals, and, being an agency man, he secured all the publications in the next day's papers. The modern long-focus lens can be worked with great success on the non-reflex camera. There are several on the market which only require an extension of the bellows equal to half the focus of the lens. They work at a fairly large aperture, and have a focussing mount. Great care must be exercised in judging the distances, but you will more often than not be able to focus the main subject on the screen before exposing. Correspondents living near the sea would find this type of lens invaluable, especially in winter, when wrecks may occur, and these very often are some distance from land. A good plate for this work must be fast, and have a fine grain, and if the light is very good I strongly advise an isochromatic with 1½ times screen. This will get through any slight ground mist. Try a long-focus lens on a portrait, and you will be surprised at the result and never go back to a short one again.

Sports Photographs

This subject is perhaps the most popular, and the variety gives the photographer scope always to try to get a new type of picture, which at the moment he does not seem very anxious to do. There is far too much of "follow the leader" among press photographers, caused, I think, by the feeling that if they all take the same events from the same angle then one of them cannot beat the rest, and there will be no grumbling by their respective managers that they have been beaten by a rival. For years the finish of the 100 yards has been photographed from the one spot—15 yards beyond the finish, until at a recent L.A.C. meeting one of the photographers had a brain wave, and tried a broad-side of the finish. This produced a very interesting result, as it illustrated the distances between the competitors when the tape was broken. The result was that nearly every paper published this photograph, even art editors who had long ago given up using finishes of sprints snapped this up as something new. The moral is obvious. I am not going to deal with the photographing of every kind of sport, as it would take up far too much space, but a golden rule to follow is to work as fast as the light will allow, and use a very fast plate. The great trouble comes in winter, when the light is weak, and under-exposure cannot be avoided. A good plan during the winter months is to use

your developer warm, but great care must be exercised if this is done, as fast plates have a tendency to fog very quickly. My own plan when I had a batch of very under-exposed football plates to develop was to put them in a tank with a weak developer, and take them out to tea with me, turning the tank over from time to time. I always found that by this method there was no sign of fog, and I always got everything out of the plates that was possible.

Very little is done with the photographing of cricket matches, except by staff photographers of papers or agencies, and I suppose this is because a long-focus lens must be used, and, if possible, a reflex camera. Cricket provides an endless number of interesting pictures, and I am certain it would pay an amateur or correspondent living near a country ground to specialise in this work, especially in view of the Australians' visit this summer.

When I started as a press photographer in Fleet Street the only cricket photographs ever taken or published showed the teams or batsmen "going out" or "coming in," and sometimes the toss, but this depended on how the captains felt. The Australians were over that year, and I went to Northampton for their first match, and experimented with the back half of an 8 in. *f*/4.8 lens on a half-plate reflex, giving me a focus of about 16 in. at *f*/10. Next day my pictures were called wonderful, nothing had ever been seen like them before. This match marked the advent of the long-focus into press-work, and within a few days of my cricket pictures long-focus lenses appeared all over the place, and cricket pictures were soon as common as any other kind. But these pictures are not easy to take if they are to be truthful, as there is always one important moment in every incident, and it is very easy to miss it. The eye, brain and hand must work together, and when the fieldsman is about to make a catch the focus must be altered to follow his movements. I cannot better illustrate what I mean than by describing an incident which happened at the Oval during a test match. England were batting against Australia, and Mr. C. B. Fry was run out. He thought the decision was wrong, and so did the majority of the spectators. Fry tried to get a third run, and threw himself full length on the ground. Four cameras exposed on the instant. Three prints showed Fry's bat home by inches, and the bails on the ground. This looked as if the umpire had made a mistake, but my picture told a very different story—the bails were in the air, and Fry's bat was not home by about 2 inches. The other photographers had exposed a shade late, but it made all the difference to the result.

Use a fast isochromatic plate and use a weak developer. Don't get too much contrast, because you will only use the centre of your negative, and the enlargement will be fairly great.

Copyright.

Copyright law is rather complicated, but at the same time one or two simple facts about it should be known to every photographer. The most important clause in the Copyright Act is the one dealing with payment when a photograph is taken, because upon these conditions the ownership of the copyright depends. The Act expressly states that when the negative of any photograph is made for or on behalf of any other person "for a good and valuable consideration" the copyright belongs to the person for or on whose behalf the work is done, which means that with an ordinary sitter at a studio the copyright is his. In the case of a landscape photographer working for an employer, all copyrights in the views taken are the employers.

Correspondents, when collecting a portrait, should always try and find out who owns the copyright. A great many portrait photographers directly they see one of their photographs published rush in an invoice for 10s. 6d., or more, but if the sitter ordered them the photographer has no claim.

VIII.—TITLES AND CAPTIONS.

Great care must always be taken when writing out titles, and a good plan is to print the names of places and people. Photographers must remember that in a great many cases the caption-writer will know little or nothing of their story, which may be quite a local one. Very often correspondents think that we in the London office know everything that has taken or is taking place anywhere and everywhere. Well, we do not, and we want the particular points of the story. Don't write a life history, but enough to describe adequately the photographs you are sending. When sending a photograph which may have three people shown and you only know the name of one, do, please, say which one it is, right, centre or left. How should we know? Yet photographers seem to think we ought to; and if you know all three names, see that you get the correct order from left to right. You would scarcely credit how touchy people are about being called in print by wrong names, but it is only natural. Be very careful that the numbers on your captions agree with the numbers on your slides. Not long ago I was dealing with a set of plates of an agricultural show in the Midlands. The list of captions said No. 6 was Lord Perhaps talking to Lady Maybe. I wanted to use this, but No. 6 plate was a very fine bull, and there were several others of people in pairs, which did not fit in with the list, so I saved the paper money and gave the show a miss. Nothing causes so much trouble in newspaper work as wrong names under photographs, and once a photographer is proved unreliable his work is shunned as "unclean."

Packing.

I am stating a fact when I tell you that many times I have received glass negatives, sometimes with card and sometimes without, sent in an ordinary envelope, and, as if to ensure its safety, it has been registered. Have the senders never heard of the machine used by the Post Office for stamping letters? because I can assure them that this machine puts an end, and a very complete one, to whatever chance their photograph had of bringing in a cheque. Always pack glass plates as described in Chapter IV.

In conclusion, I can only hope that each reader will find some little item of help in his work. There is a great deal going on in this world, and you must not feel hurt if only two of your photographs are published when you expected four. The art editor deals with all photographs on their news value; leave it in his hands, and if your work is good you will be fairly treated.

A Few "Don'ts."

Don't think, because you have read these chapters, that your troubles are at an end; they may only just be beginning—it depends on you.

Don't imagine your photographs are the only ones a newspaper will receive on a certain day—their average is over 100.

Don't rely only on photographic apparatus to obtain pictures; let your brain help, and don't be afraid to work it overtime.

Don't get the numbers of your slides mixed; papers never pay for double exposures, and blank plates cost money to develop.

Don't forget to draw the shutter of your plate-holder; it is very difficult to get a battleship launched twice.

Don't forget to set your shutter; a little light always helps in exposing a plate.

Don't hold your flashlamp near anyone's face. It is not up to you to make things worse than they are, and the local hospital may be full.

Don't swear at the art editor if your picture is not published next day; he may never have received it. The railway company may have taken a fancy to it, or you may have exposed on an empty slide.

Don't send the wrong photograph for a murderer; the Law Courts are quite busy enough at the present time.

Don't tell the audience that your flashlight never makes any smoke unless you know a quick way out of the hall.

Don't set your tripod up on a slippery floor and then feel hurt if the subject laughs: medicine bottle corks are cheap enough.

Don't forget that a press photographer changes his politics, religion and views on things in general to suit the occasion.

Don't try to retouch your negatives unless you want to spoil them; every picture paper has expert retouchers. They can turn the ugly into beauty prize-winners, and dress or undress anyone in a few minutes.

Don't forget that a little tact will make many pictures.

Don't get cross with a policeman: the law is behind him, and not you.

Don't ask permission to take a photograph if you can get it without: they might say—No.

W. Lancelot Vining.

THE EFFECT OF SAFRANINE ON DEVELOPMENT.

Many allusions have been made in recent photographic literature to the acceleration of development with hydroquinone, which results from treatment of the exposed plate with safranine. But hitherto no numerical data have been given, so that a description of some experiments dealing with this side of the phenomenon may be of interest. Kodak Portrait Film was exposed behind a step wedge to a light of 200 candle metre seconds; it was then bathed for one minute in water and immersed, after draining for a fixed time in the following developer:—

Hydroquinone	0.5 gm.
Soda carbonate	2.0 gm.
Soda sulphite	1.8 gm.
Water to	200 c.c.s.

The image appeared in 130 seconds, and development was carried on for a total time of 5 minutes, that is to say, for a factor of 3.7.

A second film was given the same exposure, but before development was bathed for one minute in a 2 per cent. (by volume) solution of Desensitol. The image appeared on the desensitised film in 18 seconds after immersion in the developer; and development was again carried on for 5 minutes, a factor of 26.

Fig. 1 shows the curves obtained by plotting the densities produced on the two negatives against exposure. It will be seen that whilst in the "desensitised" negative all the squares of the step wedge are reproduced, and nearly all fall on to the straight line portion of the curve; in the untreated negative the three lowest exposures are not reproduced at all, and the greatest density is less than half that given by the same exposure when developed after treatment with Desensitol.

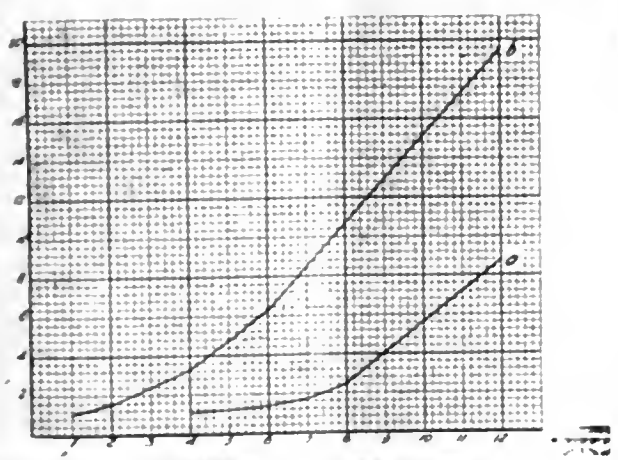

Fig. 1.—*a*, Hydroquinone; *b*, hydroquinone-Desensitol.

Similar experiments were then made with metol, using, in the first instance, a developing solution containing:—

Metol	0.25 gms.
Soda sulphite	1.0 gms.
Water to	200 c.c.s.

On the untreated film the image appeared in 53 seconds; after desensitising, in 85 seconds. Development was continued for 8 minutes, as before. Two further films were exposed and developed, with and without desensitising, in a normal metol developer, containing:—

Metol	0.25 gm.
Soda sulphite	1.0 gm.
Soda carbonate	2.0 gm.
Water to	200 c.c.s.

In this case the image appeared on the untreated film in 6 seconds, on the desensitised film in 4½ seconds.

Fig. 2 shows the curves given by these four negatives. In the absence of carbonate, safranine produces a more pronounced diminution of activity, whilst the presence of a normal amount of carbonate does not restore normal activity to the solution.

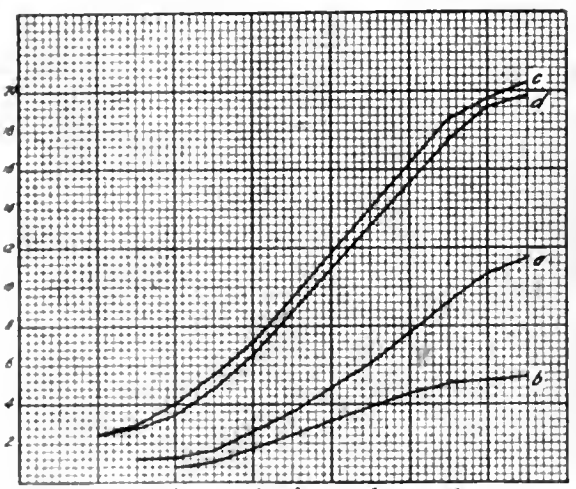

Fig. 2.—Metol—*a*, without carbonate; *b*, desensitised; *c*, Metol-carbonate; *d*, desensitised.

On comparing Figs. 1 and 2 it will be seen that the curves given by the normal metol developer are almost identical with that given by hydroquinone after Desensitol. Time of exposure and length of development was the same for both, the only essential difference being that the first developer contained 0.5 gm. of hydroquinone, as against 0.25 gm. of metol in the second. Since metol is more than twice the price of hydroquinone it appears that hydroquinone, after Desensitol, should be a more economical developer than metol.

Confirmatory tests were made on Wratten Panchromatic plates exposed in a camera, and bathed in Desensitol before development with a developer containing:—

Hydroquinone	0.5 gm
Soda sulphite	1.5 gms.
Soda carbonate	2.0 gms.
Water to	100 c.c.s.

The image appeared in 17 seconds, and gave a well graduated negative after developing for 340 seconds, *i.e.*, to a factor of 20.

Two plates were also developed, after having received equal exposures, with a rodinal type of developer. One was bathed

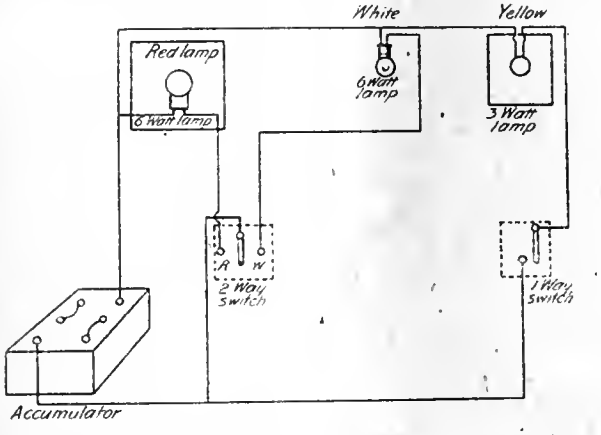
in Desensitol, and developed to a factor of 30. The second plate was immersed in a developer of the same strength, and developed for the same time as the desensitised one. The two negatives were practically identical, except that the untreated one showed a trace of fog on the rebates, although it had been developed in absolute darkness, whilst the desensitised one showed perfectly clear rebates, in spite of the fact that it had been freely exposed to red light during development.

W. ERMEN.

DARK-ROOM ILLUMINATION.

Much has been written on the above subject, and there can be no question as to the advantages of the electric light for this purpose. This is, of course, quite easily fitted where one has the current in the house or a public supply available, but, unfortunately, owing to grandmotherly legislation, there are thousands who are unable to take advantage of a public supply which should be available in all our towns. For those who can get current there are plenty of excellent dark-room lamps on the market, and my idea in this article is to point out the best way in which those who cannot get current in the ordinary way can still have all the advantages of electric light in their dark-rooms and for enlarging purposes with very little trouble and not much expense.

A word of warning is, perhaps, advisable as to the so-called dry cells, fitted in cases with a miniature lamp. Except for the



most temporary use while travelling just for plate changing, they should be regarded as useless, unless one is prepared to pay through the nose for refills; as for serious work in the dark-room, it is simply throwing money away. Now the first thing to obtain is a *6*-volt accumulator in celluloid case. This should be of ample capacity, not less than 40 ampère hours (actual), not ignition capacity (this latter term is most misleading to the uninitiated). 60-ampère hours actual would be much better if much dark-room work is done, but do not on any account be persuaded to purchase a second-hand one; go to an electrical engineer, and get him to have a proper first charge put in, as this first charging is the most important, since on it depends the whole life of the accumulator. You will then want two or three 6-volt motor car side lamps and holders. One should be 3-watt and the other ones 6-watt size. Then get a few yards of electric light flexible cord and one ordinary and one two-way and off switches, and join them up as diagram. This will give you a good light for bromide printing, a good light in your lamp, and a white light for general illumination. I strongly advise the use of a safe light in the lamp, and, this being connected up as shown, it is impossible to have a white light alight at the same time as a red or other safe light. This is a great advantage; the bromide lamp is left alight all the time, and is simply covered with a piece of yellow paper, which gives ample light for putting the paper on negative. The white light is then used for the exposure. I have had this arrangement in use for a long time.

Should it be desired to do some enlarging, it will be necessary to get a motor car head lamp and holder, 6-volt 12-watt. This will be found to give ample light for a lantern for enlarging, and the light is of the right kind in colour and form, being almost a point. Of course, the accumulator will have to be charged occasionally, but it is surprising how long it will last on one good charge. It depends on the use it has, but by way of giving some idea how often this will be necessary a 40-ampere hour battery will run the darkroom lamp *continuously* for about *40* hours before requiring to be recharged, which can be done at almost any motor garage.

This article is addressed more to the really serious amateurs, and for that matter to professionals as well, and not to the button-pressing fraternity, who leave it all to Faith, Hope and Charity (Faith in the local chemist, Hope that there is something on the film. Charity—this latter dispensed by the owners of the faces on which attempts have been made). I can assure anyone who proposes to try this system of dark-room illumination that it is a treat to work with it. Admittedly it costs a little to start, but the amount greatly depends on the individual; the serious amateur is generally a handy man with tools. I shall be only too glad to give anyone any further information if it will help along the best of all hobbies.

WM. GARD.

CURIOUS ACCIDENT WHILE BEING PHOTOGRAPHED.—A seventeen-year-old lady school teacher of Bath is the heroine of a remarkable rescue from drowning. With her mother, she accompanied a party of friends to the meadows bordering the Avon, near Grosvenor Bridge. She had a camera, and desiring to photograph her mother, selected a picturesque setting on the high bank of the river, where the lady posed, leaning against a post. The daughter went a few paces away to focus, but on glancing up before making the exposure, was horrified to find the post had given way and her mother had disappeared into the water. Instantly the daughter, an accomplished swimmer, plunged in to the rescue, and succeeded in freeing her mother from some obstruction which held her down, and bringing her ashore. The mother was unconscious, but revived under respiratory attention

AMIDOL DEVELOPER.—Quoting the recent article of ours on the properties and preservation of the amidol developer, Dr. D'Arcy Power, in "Camera Craft," adds the following note:—"I have used amidol exclusively for the last ten years for plates—including Autochromes, Paget colour plates, lantern slides, bromide prints and enlargements. In all these fields I have found it as good as any other developer and for some purposes better. I dissolve a pound of sodium sulphite in half a gallon of water (64 ozs. in English measure.—EDS., 'B.J.'), add two ounces of sodium bisulphite, and one ounce of potassium bromide. This is a stock solution to be diluted from one in three to one in six. The amidol is added at time of using, according to required contrasts, in from three grains to half a grain an ounce of diluted developer"

EXPERIMENTS ON SULPHIDE TONING.

(A communication, No 116, from the Research Laboratory of the Eastman Kodak Company.)

I. *The Effect of Modification of Ordinary Indirect Sulphide Toning.*

THE ordinary indirect (or "re-development") method of sulphide toning, as described, for example, on page 461 of the "British Journal Photographic Almanac" for 1921, was followed, and, without making any very radical alteration at any point in the process, systematically modified, with the object of discovering just what the conditions are which influence the final tone, and the direction and extent of this influence. Then, the ordinary method was more profoundly altered. However, there were not included any of those variations, such as the addition of copper or mercury salts or bichromates to the bleach solution or the use of Schlippo's salt in the darkening bath, which are known to change the composition of the final toned image.

First, in order to avoid complications due to variations in the character of the silver images taken for toning, the method of obtaining these images was standardised as follows: (1) All experiments were made on each of two emulsions, "Special Velvet Velox" and "Artura Carbon Black," from two different negatives. (2) Development always followed exposure either immediately or after an interval of not more than about one hour; and the papers were immersed directly in the developer without any preliminary soaking in water.

TABLE I.

EXPERIMENTS IN VARYING THE METHOD OF BLEACHING.[1]

Series	Expt. No.	On effect of	Solution used.	Time of Action.	Result.	Remarks.
A[2]	2	Composition of bleach bath.[3]	(*a*) 40 gms. ferricyanide per litre (*b*) 30 gms. ferricyanide + 10 gms. am. brom. per litre. (*c*) 20 gms. ferricyanide + 20 gms. am. brom. per litre. (*d*) 10 gms. ferricyanide + 30 gms. am. brom. per litre.	30 minutes .. 2 „ .. 2 „ .. 2 „ ..	(*a*) Colour more yellowish than normal. (*b*), (*c*) and (*d*) Indistinguishable, normal results.	
A	3	Total concentration of salts in bleach bath.	Ratio of ferricyanide : bromide kept constant at 3 : 1, the ferricyanide used in concentrations of (*a*) 10%; (*b*) 3%; (*c*) 1%; (*d*) 0.3%.	(*a*) 2 minutes .. (*b*) 2 „ .. (*c*) 3 „ .. (*d*) 15 „ ..	(*a*) Colour more yellowish than normal; slight loss of image in high-lights. (*b*), (*c*) and (*d*) Indistinguishable, normal results.	
A	6	Duration of washing between bleaching and darkening.	.. ..	(*a*) No washing, 30 sec., 20 mins., and 18 hrs. (*b*) 3 min. (normal) vs. 17 hrs.' washing.	(*a*) No concordant results obtained. (*b*) 17 hrs.' washing produced more yellowish colour than normal.	
B	1	Ferricyanide vs. ferricyanide - halide as bleach bath.	(*a*) 3% Ferricyanide .. .. (*b*) 3% Ferricyanide + 1% potass chloride (*c*) 3% Ferricyanide + 1% potass bromide. (*d*) 3% Ferricyanide + 1% potass iodide.	.. .. ..	(*a*), (*b*) and (*d*) Slower than (*c*). (*a*) and (*b*) gave same tone, which was more yellowish than that from (*c*). (*d*) Still yellower than (*a*) and (*b*).	The yellowish colour in the case of (*d*) is not changed by even greatly prolonging the time of immersion in darkening bath.
B	3	Substituting potass sulpho-cyanide for potass bromide in usual bleach.	(*a*) 3% ferricyanide + 0.3% Sulphocyanide. (*b*) 3% ferricyanide + 0.1% sulphocyanide.	(*a*) .. .. (*b*) Somewhat longer than usual.	(*a*) Useless, because of solvent action. (*b*) Slight solvent action; gave with some papers a purplish tone.	
B	4	Substituting potass selenocyanide for potass bromide in usual bleach.	(*a*) 3% ferricyanide + 0.3% selenocyanide. (*b*) 3% ferricyanide + 0.1% selenocyanide.	.. ..	(*a*) Slight red stain, yellowish tone. (*b*) More yellowish tone than normal.	
B	5	Substituting potass cobalticyanide for ferricyanide in usual bleach.	2% cobalticyanide + 1% potass bromide.	3 hours	No perceptible bleaching action.	
B	6	Potass cobalticyanide alone as bleach.	2% solution cobalticyanide ..	Over night ..	No bleaching action.	

1. It may be remarked here that, while throughout these experiments ammonium bromide has been used, dry *sodium* bromide in equal weight gives indistinguishable results. This is true also of potassium bromide; in this case, however, it is desirable, for safety with continued use, to increase somewhat the amount of the salt taken; and 12 gms. per litre of potassium bromide is accordingly recommended in place of 10 gms. of either ammonium or sodium bromide.

2. Experiments in Series A were done in co-operation with Mr. D. S. Mangello.

3. We have not tested experimentally the effect of composition on the *useful life* of the bleach bath; but, assuming the equation:

$$4Ag + 4K_3Fe(CN)_6 + 4NH_4Br = 4AgBr + 3K_4Fe(CN)_6 + (NH_4)_4Fe(CN)_6,$$

as representing the action of bleaching, it can be calculated that potassium ferricyanide and ammonium bromide will be withdrawn from the bleach bath in the ratio 33.6 : 10; and the use of a bath containing these salts in the ratio 30 : 10 will probably ensure that as long as the bath will bleach at all it will bleach satisfactorily as regards the final tone.

TABLE II.

EXPERIMENTS IN VARYING THE METHOD OF DARKENING.

Series.	Expt. No.	On effect of	Solution used.	Time of action.	Result.	Remarks.
A	8	Concentration of sodium sulphide in the darkening bath.	(*a*) 0.01% sodium sulphide ..	(*a*) 2 hrs.	(*a*) More yellowish than normal.[1]	
			(*b*) 0.03% „ „ ..	(*b*) 30 min.	(*b*) Slightly more yellowish than normal.	
			(*c*) 0.1% „ „ ..	(*c*) 15 „	Others normal.	
			(*d*) 0.3% „ „ ..	(*d*) 3 „		
			(*e*) 1.0% „ „ ..	(e) Normal		
			(*f*) 3.0% „ „ ..	(*f*) „		
			(*g*) 10.0% „ „ ..	(*g*) „		
			(*h*) 30.0% „ „ ..	(*h*) „		
A	11	Presence of hypo in the darkening bath.	(*a*) 1% sodium sulphide+0.3% hypo.	(*a*) Normal	(*a*) and (*b*) Normal tone.	These results confirm Carnegie's investigation of this point.
			(*b*) 1% sodium sulphide + 1% hypo.	(*b*) „		
			(*c*) 0.3% sodium sulphide+1% hypo.	(c) 3 min.	(*c*) Slightly more yellowish than normal.	
			(*d*) 0.1% sodium sulphide+1% hypo.	(*d*) 15 min.	(*d*) Distinctly yellower than normal.	
B	7	Potass cobalticyanide + soda sulphide on silver images.	2% cobalticyanide + 1% sulphide	.. ..	Toning action slow; tone resembling that given by the polysulphide bath.	Sulphide alone, in presence of atmospheric oxygen, tones to a similar colour, but very slowly.
B	9	Bath of soda carbonate immediately prior to darkening.[2]	(*a*) 0.1% soda carbonate ..	10 min.	(*a*) Produced purplish tone	This is a useful effect for the majority of D.O. papers; to produce it an immersion of 10 sec. in 1% soda carbonate solution is recommended.
			(*b*) 0.3% „ „ ..	10 „ ..	(*b*) More pronounced purplish	
			(*c*) 1.0% „ „ ..	10 „	(c) Like (*b*).	
			(*d*) 3.0% „ „ ..	10 „	(*d*) and (*e*) More nearly normal tone.	
			(*e*) 10.0% „ „ ..	10 „		
B	10	Soda carbonate bath immediately prior to darkening, the time of action being varied	1% soda carbonate	5 sec. ..	No differences in final tone, showing that a very brief immersion is all that is needed to change the final tone.	
				20 „		
				1 min.		
				3 „		
				10 „		
B	12	Soda carbonate as in B. 9, used after bleaching to AgCl.	.. ..	.. ..	Results as in Expt. B 9.	
B	11	Bleaching to images of silver chloride, silver ferricyanide, silver ferrocyanide and silver bromide.	For bleaching, see last column. Darkening as usual.	.. ..	Chloride images gave more purplish tone than usual method. Ferricyanide and ferrocyanide gave less purplish (more yellowish) than usual method. Bromide, of course, was normal.	For bleaching, to silver chloride image use freshly mixed solution containing 0.2% potass permanganate, 3% sodium chloride, and 1% sulphuric acid. Transfer directly to clearing bath of 2% sodium bisulphite+1% sulphuric acid, and wash 5 minutes. To convert to ferricyanide image, use bath of 9% potass ferricyanide+0.1% potass permanganate. Wash 30 min., clear in 5% oxalic acid solution and wash 20 min. By using 1% sodium bisulphite for clearing instead of oxalic acid and leaving until orange colour disappears, the image is ferrocyanide. For bromide image use usual ferricyanide-bromide bleach
B	13	Adding potass iodide..	1% potass iodide added to usual bleach, to the darkening bath; or 1% potass iodide bath used immediately before darkening.	.. ..	Final tone rendered more yellowish in each case.	
B	14	Polysulphide vs., usual darkening bath.	(*a*) 1% solution of potass pentasulphide.	(*a*) 1 min.	Polysulphide gives much yellower tone.	
			(*b*) 1% solution of sodium-sulphide.	(*b*) 1 „		
B	16	Adding potass seleno-cyanide to darkening bath.	Usual darkening bath + up to 2% seleno-cyanide.	.. ..	Additions up to 2% give progressively increasing yellowish tone.	

1. We thought at first that this phenomenon, which was described by Douglas Carnegie twelve years ago ("B.J.," 1909, p. 666), might be entirely explained by the action of the thiosulphate formed by the rapid aerial oxidation of very dilute sulphide solutions; but experiments in which thiosulphate was present from the beginning, and other experiments in which oxidation was kept at a minimum by using frequently changes of freshly-prepared sodium sulphide solution, have not supported this view, and we are inclined to believe that a very dilute solution of sodium sulphide, even if perfectly pure, would give a tone deviating from the normal in the direction of yellow, and increasingly so with increasing dilution of the bath.

2. The colour changes resulting (during rapid coagulation) from the addition of various electrolytes to colloidal solutions of silver sulphide (in glass vessels) have been observed and described by F. V. v. Hahn ("Kolloid-Zeitschrift," October, 1920, p. 172).

(3) The developer used for the Velox paper was the following:—

Elon	0.9 gm.
Hydroquinone	3.6 gms.
Sodium sulphite (des.)	14 gms.
Sodium carbonate (des.)	19 gms.
Potassium bromide	0.46 gm.
Water to	1000 c.c.s.
Methyl alcohol	23 c.c.s.

The time of development was 45 seconds, the temperature of the developer having been adjusted to 20 deg. C. (68 deg. F.). For the Artura paper the following developer was used:—

Elon	1.7 gms.
Hydroquinone	6.7 gms.
Sodium sulphite (des.)	21.7 gms.
Sodium carbonate (des.)	15 gms.
Potassium bromide	1.7 gms.
Water to	1000 c.c.s.

In this case the time of development was 3 minutes, the temperature being, as before, 20 deg. C. (68 deg. F.) (4) All prints were transferred from the developer to an acid stop-bath of 3 c.c.s. of concentrated sulphuric acid per 1000 c.c.s. of water. (5) The fixing bath used was the following:—

Chrome (potassium) alum	6 gms.
Sodium bisulphite	10 gms.
Water to	50 c.c.s.
Hypo 35 per cent. solution to ...	1000 c.c.s.

Two trays of this were in use, the prints being allowed at least 5 minutes in each tray in succession. (6) After fixing, the prints were washed for a total time of at least 30 minutes in running water with, intermediately, at least one transfer of the prints, one at a time, from one tray to another. (7) The washed prints were mopped with clean towels and left to dry, face down, on muslin-covered frames. (8) When dry, the prints were examined visually, and only those from each negative and on each kind of paper that were indistinguishable in contrast and average density, and otherwise apparently perfect, were kept for toning.

The following conditions were taken as representing the normal procedure in indirect sulphide toning:—(1) The print

TABLE III.

Variations in Bleaching and Darkening which did not Affect the Final Tone.

Series.	Expt. No.	On effect of	Method of treatment.	Result.
A	1	Soaking in water immediately prior to bleaching.[1]	No soaking vs. 5 hours' soaking	No difference in final tone.
A	4	Duration of immersion in bleach bath	Immersed for 1 minute, 3 minutes, 10 minutes, 30 minutes at 20° C.	No difference in final tone.
A	5	Temperature of bleach bath	Used at 10° C., 20° C., and 30° C., for times decreasing from 4 minutes for 10° C. to 1 minute for 30° C.	No difference in final tone.
A	7	Exposure to light during washing between bleaching and darkening.	Four gradations of light, from total darkness to midday sunlight. Duration of washing, 3 minutes.	No difference in final tone.
A	9	Duration of immersion in darkening bath.	Immersed for: 1 minute, 2 minutes, 4 minutes, and 8 minutes.	No appreciable difference in final tone, though prolonged immersion caused softening of gelatine, which made exact comparison impossible.
A	10	Temperature of darkening bath ..	Used at 10° C., 20° C., and 30° C., for 2 minutes, 1 minute, and ½ minute respectively.	No difference in final tone.
A	12	Use of hardening bath after darkening and before final washing.	Hardening baths used were: (*a*) 4 gms. ordinary alum, 4 gms. soda sulphite, dry; 8 gms. glacial acetic acid; water to 1,000 ccs. (*b*) 6 gms. chrome alum; 10 gms. soda bisulphite; water to 1,000 ccs.	No difference in final tone.
A	13	Duration of final washing	Washed for 5 minutes, 40 minutes, 5 hours, and 40 hours.	No difference in final tone.
A	14	Rate of drying of toned image ..	(*a*) Very slow drying, in moist air (8 hours). (*b*) Ordinary drying on muslin-covered frame (2 hours). (*c*) Quick drying, by electric fan (15 minutes). (*d*) Very rapid drying, by hot-air blast (about 1 minute).	No difference in final tone.
B	2	Usual ferricyanide bromide bleach vs. successive baths of ferricyanide and bromide.	(*a*) Usual procedure with usual bleach. (*b*) Immersed in 3% potass ferricyanide until "bleaching" completed, washed 3 minutes, and immersed in 1% potass bromide 2 minutes.	No difference in final tone.
B	8	Bromine water as bleach bath ..	Bleached in bromine water, washed 10 minutes, and darkened as usual.	No difference in final tone, though emulsion is stained, due probably to effect of bromine water on traces of metallic impurities in the emulsion.
B	18	Adding potass bromide to darkening bath.	Added up to 5%	No difference in final tone.

1. If, however, the prepared black-and-white print is not allowed to dry between washing and bleaching, the tone is altered slightly in the direction of purple.

is immersed *dry* in the bleach bath. (2) The bleach bath has the composition:—

Potassium ferricyanide	30 gms.
Ammonium bromide	10 gms.
Water to	1000 c.c.s.

The time of immersion is 2 minutes, and the temperature of the bath 20 deg. C ± 2 deg. C. (64 deg. F. to 72 deg. F.). (3) When bleached, the print is washed in running water for 3 minutes. (4) It is then immersed in 1 per cent. sodium sulphide (Na_2S) solution for 1 minute at 20 deg. C. ± 2 deg. C. (64 deg. F. to 72 deg. F.). (5) It is then washed for 30 minutes in running water. (6) Finally, the free moisture is removed by means of a clean towel and the print is allowed to dry spontaneously, face down, on a muslin-covered frame.

The water used for making up all solutions in the experiments was distilled water, and the running water used for washing the prints was Lake Hemlock water of the Rochester City supply.

The experiments and results have been summarised in tables, Table I. giving the effects of modifying the method of bleaching prints preparatory to darkening, and Table II. indicating the changes produced by variations in the composition and manner of use of the darkening bath. Many of the experiments which would normally be included in Table I. or Table II. gave negative results in that the final tone of the print was in no way different from that obtained by the usual procedure. These have been grouped in Table III.

The results of experiments on the polysulphide method of toning (Series C) are given in Table IV.

The above experiments show that simple variations of the usual procedure in the indirect sulphide toning (re-development) method may modify the final tone in the direction of either a more purplish or a more yellowish colour, the former to but a slight degree. The maximum purplish tone is obtained by bleaching to an image of silver chloride and then using a bath of sodium carbonate immediately prior to darkening, as in Experiment No. B 12. By merely bleaching to a chloride instead of to a bromide (Experiment No. B 11), or again by merely interposing a bath of sodium carbonate in the usual method immediately before darkening (Experiment No. B 10), the resulting change is smaller in extent, but still distinctly useful. The change of tone in the direction of a more yellowish colour, on the other hand, may be brought about to a comparatively large extent, and in a variety of ways. The substitution, partially or completely, of sodium sulphide by potassium pentasulphide (or by "liver of sulphur") in the darkening bath (Experiment B 14), or the addition of a soluble iodide to either the usual bleaching or darkening bath (Experiment No. B 13), can be recommended for this purpose. But for most emulsion papers increased yellowness of colour is undesirable. From a practical point of view, therefore, and assuming that the black-and-white print has been sufficiently developed and fully fixed and washed, it is only necessary to *avoid* the following conditions in indirect sulphide toning:—

1. Entire absence of soluble bromide from the bleach bath.

2. The use of a bleach bath containing an excessive concentration of soluble bromide. (In which case there is an appreciable loss of image by dissolution of silver bromide in the bath.)

3. Excessive duration of washing between bleaching and darkening.

4. Excessive dilution of soluble sulphide in the darkening bath.

5. Presence of hypo in the darkening bath, to an extent considerably relative to the sulphide.

TABLE IV.

Series C. Expt. No.	On effect of.	Method of treatment.	Effect on rate of toning.	Remarks.
1	Time of immersion in the polysulphide bath.	Immersed in toning bath: (*a*) 15 minutes; (*b*) 30 minutes; (*c*) 60 minutes. Washed 30 minutes; left to dry on muslin-covered frames.	.. ..	Prolonged immersion tends to produce increased yellowness of tone.
2	Adding "hypo" to the polysulphide bath.	35% "hypo" in quantities of 1/10 of volume, 1/5 of volume, and ¼ of volume of bath.	None	Therefore the toning action of the bath in the Fenske process (British patent 18545 of 1912) is apparently due essentially to its content of polysulphide.
3	Adding potass. iodide to the polysulphide bath.	Potass. iodide in amounts of 0.1%, 0.3%, 1%, and 3% was added to the polysulphide bath.	None	No effect on tone.
4	Adding potass. sulphocyanide to the polysulphide bath.	0.5% to 10% potass. sulphocyanide was added to the usual bath.	Increased with increasing concentration of sulphocyanide.	Presence of 2% sulphocyanide approximately doubles the rate of toning. No difference in colour. Colour modified to a purplish tone, intermediate between the polysulphide tone and that characteristic of a single-solution selenium bath.
5	Adding potass. selenocyanide to the polysulphide bath.	10 ccs. of 5% potass. seleno-cyanide added to 60 ccs. polysulphide bath.	Greatly accelerated ..	No effect on tone.
6	Adding thiosinamine to the polysulphide bath.	1% added to bath..	Somewhat accelerated.	No effect on tone.
7	Adding thiocarbamide to the polysulphide bath.	1% added to bath..	Greatly accelerated ..	No effect on tone. Thiocarbamide alone in 1% solution has a very slow toning action, accompanied by loss of image. No loss, however, when used with the polysulphide bath.

II. *The Polysulphide Method of Direct Sulphide Toning.*

"Potash Liver of Sulphur," which is produced by fusing together potassium carbonate and sulphur in a closed vessel, consists essentially of a mixture of "potassium polysulphide" and potassium sulphate. Potassium carbonate and potassium thiosulphate may also be present, according to the conditions of manufacture and the extent of the subsequent exposure of the product to the air. The only one of these substances which alone in aqueous solutions is capable of toning a silver image

is potassium polysulphide; and therefore, if we assume the absence of any interdependent effect of the constituent compounds of potash liver of sulphur in the process of toning, we must conclude that the only effective toning agent in potash liver of sulphur is potassium polysulphide.

A solution of potassium polysulphide may be conveniently prepared as follows:—Dissolve one hundred gms. of potassium hydroxide in water and make up to 1,000 c.c.s. Saturate 500 c.c.s. of this solution with hydrogen sulphide, and mix with the remaining 500 c.c.s. To this solution, which is substantially one or normal potassium sulphide (K_2S), add 120 gms. of pure sulphur in powder, heat the mixture to boiling, stirring constantly, and boil for about five minutes. The solution, which is now substantially one of potassium pentasulphide (K_2S_5), is allowed to cool, filtered, and kept, preferably in the dark, in a rubber-stoppered bottle. For use as a single-solution toning bath, this stock solution may be diluted with twenty times its volume of water to give a bath containing approximately 1 per cent. of potassium pentasulphide. The turbidity which usually appears upon diluting with water is due to the separation of finely divided sulphur. This is not seriously detrimental in toning, but a clear solution may be obtained, if desired, by adding a little sodium sulphide solution (and warming, if necessary), or by filtering the diluted solution, or by allowing the precipitate to settle and pouring off the clear liquid.

The bath used in the following experiments was made by taking 950 c.c.s. of water, adding 50 c.c.s. of the stock solution of polysulphide and then immediately 2.5 c.c.s. of 20 per cent. solution of sodium sulphide (Na_2S). This bath when in use in a photographic tray will remain clear for an hour or so, after which sulphur may commence to separate out. The odour of this bath is not nearly so objectionable as the usual sulphide bath.

The results of experiments in varying the composition, etc., of the baths used in the polysulphide method of direct toning are given in the table on page 450.

The practically useful conclusions from this short third series of experiments are that it is possible (1) to prepare a polysulphide toning bath containing about 1 per cent. potassium pentasulphide and 1/20 per cent. sodium sulphide, which tones satisfactorily, although somewhat slowly; and (2) to accelerate the rate of toning of this bath by the addition of either potassium sulphocyanide or thiocarbamide.

We may add the following general notes on sulphide toning, both "liver" and "bleach and sulphide":—

First, the character of the emulsion has a very great influence on the result. As a rule, it may be said that the fastest papers give a purplish and the slowest a yellowish tone. Secondly, with a given paper and given method of toning the degree of development has a considerable influence, although this influence can in extreme instances be entirely overshadowed by the character of the emulsion. Thirdly, with a given paper and given method of making the black-and-white print, the two principal direct sulphide toning methods ("hypo-alum" and "polysulphide") give results identical with each other, while the indirect sulphide toning method gives, as is well known, a very different result—namely, one which is comparatively yellowish. Finally, it may be remarked that the effect of the often-recommended use of a preliminary sulphide bath in the indirect sulphide toning method is to give mixed direct and indirect sulphide toning; and the results, while often excellent in quality of tone, depend largely upon the exact procedure followed, and therefore are apt to vary in colour.

E. R. Bullock.

MAKING AN EFFICIENT ENLARGING EASEL.

There are so many types of enlarging easels on the market, and so many designs have been put forward for home-made ones, that another might seem to be superfluous. I am convinced, nevertheless, that the one I am going to describe has certain advantages over many others, and is simple to make, requiring no expensive materials or tools, nor any great skill. It may be limited in size, the principal part being constructed from a printing frame, but old frames up to 15 × 12 are still to be found among professional junk and in brokers' shops. For smaller work only, there is no advantage at all in having an easel larger than the largest enlargement likely to be made.

Besides the easel, we require a strip of wood about 3 in. wide by ¾ in. thick, a couple of small hinges, a few screws, and a piece of stiff mounting board. The frame should preferably have an equally divided and hinged back, and if this is not the case, it is worth the extra trouble to construct such a back roughly from ½-in. or ¾-in. wood. The springs are first removed from the frame,

Fig. 1.

and a piece of good flawless glass found to fit it tightly. A cleaned-off negative will serve if the edges are bound with slide-binding to secure the necessary fit. A stiff piece of mounting board is cut to fit the frame comfortably, but not tightly, and if this has one pure white side, it will be an advantage. Failing this, a sheet of white paper should be mounted on to it, and then, on the white side, sizes of smaller enlargements are drawn. In the case of 15 × 12 easel, the sizes 12 × 10, 10 × 8, 8½ × 6½, and half-plate can be drawn alternately in black and red inks. One of the springs is screwed to a corner of the easel, in such manner that it can be used to hold the board tightly in the easel. Failing a sufficiently strong board, the two springs can be used, one at each of two opposite corners. Fig. 1 shows the position and use of a single spring.

The strip of 3-in. wood is fashioned into a leg for the frame, and is cut of such a length that when one end is screwed to the front of the frame, as shown at B, fig. 2, and the whole is stood up on the leg, the centre of the frame will be brought to a height

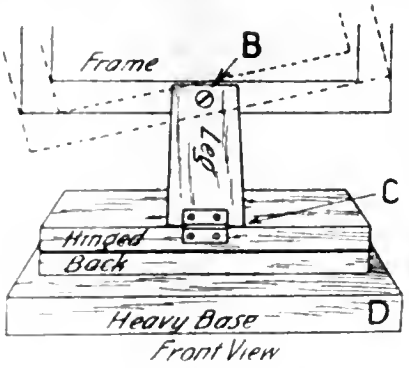


Fig. 2.

about 1 in. below the normal level of the lens in the enlarger. The leg is secured with one screw only, which should be of the short, fat variety, and care is necessary when putting in the screw if we would avoid splitting the frame. If the leg and frame can be cleanly drilled with a brace and bit or a red-hot tool, a bolt and wing nut will be superior to a screw.

The leg being cut, the bottom front edge is fastened to one end of the back, as shown at C. If the back is a heavy, substantial one, the easel is now finished, but a heavier base can be made

by screwing the other half of the back to a square of thick wood, as shown at D.

In use, the easel is placed before the lantern and moved about till each corner of the frame is the same distance from the centre of the lens as the other three corners, the lens being at its normal height. In this position, lines can be drawn on the bench along the side edges of the easel base, or thin trackers can be tacked down, between which the easel can be moved forward or backward.

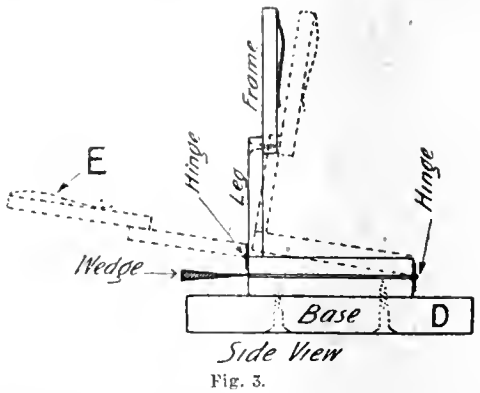

Fig. 3.

With the white board in position, focussing is done, and then the easel is pushed over on its front hinges into the position shown at E, where the board is lifted and the bromide paper inserted between it and the glass, after which the easel is pushed up again and the exposure made.

The joint B allows an amount of swing which is useful for quick straightening, and a thin wedge of wood or cardboard inserted between the two halves of the back will tilt the easel out of the vertical when tilt is required to correct leaning buildings, etc. If further elaboration is desired, the leg can be made in two pieces, when by slotting one and drilling the other, the two can be fastened together by a bolt and wing nut, and the frame can then be easily raised and lowered. In this case the joint at B can be made a fixture, as the side tilt will be obtainable at the lower joint.

I have carefully tried out an easel made as above, and, given careful construction, with attention to the rigidity of joints, the stiffness of the white board, and the strength of the spring, this piece of apparatus is distinctly useful. THERMIT.

MASK MAKING.

To those who have never had occasion to make a printing mask, the cutting of this important little article might not appear difficult, but the printer who does a great deal of masked printing knows how much trouble can be taken in getting that degree of accuracy which is so necessary to a good mask.

Masks can be bought, but if it is possible to cut one's own quickly and accurately, greater satisfaction will be obtained. For instance, where various sizes are in constant use, as in an "amateur finishing" workroom, if bought masks are the rule, it is necessary to keep a stock of each size used, and in the case of an odd-sized negative, or anything else necessitating an odd-sized mask, the printer is reduced to the doubtful process of fixing two or three masks together.

By regularly cutting one's own masks, only a small stock of material is necessary, and any negative can be covered in any desired way.

Of the various materials which serve for mask making there is one that has certain advantages. It is the thin orange celluloid supplied by Messrs. E. B. Fry, Ltd., of Pratt St., N.W., which can be obtained in blanks of required sizes. It is stronger than paper, but thin enough not to interfere with good contact, if used between negative and printing paper. It is transparent enough to see through, but sufficiently opaque to actinic rays to preserve the borders. Masks made of this celluloid last well if handled with anything like reasonable care.

Sheet celluloid for masking can be cut expeditiously in the following manner:—The desired opening is first drawn in pencil on a piece of white paper or card the same size as the blank. If a good inch rule and a small right-angled set-square are used, it is a simple matter to draw any rectangular size correctly. The next step is to fix the blank over the drawing with a couple of wire paper fasteners or pins. With pins, care must be taken not to crease the blank, which will not stand doubling to push a pin through. Laying the two on a sheet of glass or an old negative, with the blank up, the design is traced on the blank with a sharp darning needle or a long-handled push pin. It is only necessary to scratch the celluloid. No attempt should be made to cut through. The celluloid will break cleanly along the scratches when bent back, just as glass does when scratched by a diamond. The bending must not be done until the complete design has been traced and the blank removed from the drawing, and care must be taken not to bend too violently, or the lines may split past the corners. But it is not difficult, and with a little practice a perfect mask can be cut this way in something under a minute, though such haste is not exactly advisable. The drawing will do for any number of future masks if not thrown away or damaged.

Circles can be cut by fixing a push pin in the pencil holder of a pair of compasses. In this case the underlying design can be dispensed with. With masks over of quarter-plate size and over, the centre pieces are large enough for further use. For examples, the piece from a 5 × 4 mask will make a good 2Brownie mask, and that from a quarter-plate will provide a v.p., or we can get in the same way a p.c. and a 1A mask out of the same half-plate sheet of celluloid. Thus, for quantity mask users the material is economical. THERMIT.

FORTHCOMING EXHIBITIONS.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 11 to 16:—

PRINTING FRAMES.—No. 18,696. Printing frames. W. Aitken.

PRINTING MACHINES.—No. 18,702. Machines for photographic printing. S. H. Morse.

OPTICAL PROJECTION.—No. 18,706. Automatical optical projection apparatus. F. Ontrey.

STEREO-CINEMATOGRAPHY.—No. 19,213. Production of stereoscopic moving pictures. H. Windebank

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

STRIPPING OR TRANSFER PAPERS.—No. 164,448 (March 2, 1920). The invention relates to photographic transfer processes in which the film of photographic emulsion after being exposed, developed, fixed, and washed to form a positive picture, is transferred from its original base or support to a mount of wood or other suitable material, by means of a suitable adhesive, for example, a 5 per cent. solution of warm gelatine, in the usual and known manner, the base, after drying, being then stripped off.

manufacture of the [illegible] for use in
process, the base is [illegible] which has
passed through a bath of [illegible] dried, and is
then has been appl[illegible] to enable the water
to be applied evenly to the [illegible] first instance, to
the emulsion from stripping [illegible] during the
operations, and afterwards [illegible] printing
stripped from its original [illegible] required. This
film in certain cases con[illegible] waterproof
such as sandarac or [illegible] however, being

certain glycerine is also [illegible]

A plain photographic [illegible], a paper which
baryta coating) is impreg[illegible] paraffin wax by passing
through a bath of paraffi[illegible] low degree of saturation
for example, 10 grs. of par[illegible] dissolved in 1 oz. of
is a suitable strength.

This waxed paper, when [illegible] coated on one side only with
a substratum which may be [illegible] as follows:—

1 oz. water.
4 drachms of 5 per cent. [illegible] chrome alum.
1 oz. alcohol or methyla[illegible]
4 dr. of 2 per cent. solut[illegible] quillaia bark.
½ dr. glycerine.

The alcohol may be omitt[illegible] that case the substratum
will take a much longer ti[illegible]

The chrome alum is empl[illegible] only for its hardening and
binding effect, but also as [illegible] of frilling and blistering
the quillaia bark to enable [illegible] and even flow of the
tion over the surface of the [illegible] paper, and the glycerine
give flexibility and to bind [illegible] ingredients. The
stratum is applied to the [illegible] in the usual manner,
in leaving the bath the [illegible] subjected to the action of
one or more warm-air [illegible] in order to reduce
quantity of the substratum [illegible] the base.

An ordinary photographic [illegible] emulsion is then applied
over this substratum [illegible] the usual manner, and
positive print taken [illegible] developed and toned by the
standard formula whilst [illegible] usual base.

In the preparation of the [illegible] intended for transfer
photographs on to wood, [illegible] previous formula should be
altered to the following, [illegible] also be varied to suit
circumstances:—

Water, 1 oz.
Chrome alum, 2 dr. [illegible] solution.
Alcohol, 1 oz.
Quillaia bark, 1 dr. [illegible] solution.
Glycerine, 1 dr.

After developing, [illegible] and washing the print in the
a warm 5 per cent. gelatine solution is brushed [illegible]
side of the wet print, which is to be ironed into the
known manner. The print is laid on the fabric, and
or flannel blotting-paper placed under the fabric [illegible]
print, and an iron heated to 150 to 200 deg. F. [illegible]
passed over the cloths, or blotting-paper, with [illegible]
pressure, until the print is dried. The wax paper
stripped off in the ordinary way. The fabric with
pictures can be afterwards placed in a bath of 2 per
lime solution (which may also contain glycerine) for
minutes at atmospheric temperature, and dried [illegible]
or otherwise, the [illegible] being only required to remove
The fabric is then washable by ordinary domestic
without affecting the photograph.

A quantity of the base coated with this substratum
is rolled, packed, and sent away to be afterwards coated

in accordance with the manner in which the photographic matrix is obtained, and in some instances both a male and female embossing die may be formed between which the prints can be embossed.

Plastic casein suitable for carrying out the invention may be prepared in various ways: for example, casein mixed with lime or other alkaline material is converted by the action of water into a plastic mass which dries so as to form a transparent, hard, elastic mass. Also sulphonated rape oil may be mixed with dried powdered casein and kneaded into a homogeneous gelatinised mass, to which resin or caoutchouc and chalk or lime may be added, and the product hardened by vulcanising with sulphur or exposing it to the action of formaldehyde. A solution of casein may also be mixed with a solution of resin and incorporated with lime, or any suitable vegetable or mineral ingredients, and hardened with formaldehyde. Plastic casein may also be obtained by heating milk to 140 deg. F., adding borax, and raising the temperature to 190 deg. F., in the presence of barium chloride or other mineral precipitant of casein. The washed precipitate is pressed and ground with an addition of acetic acid, soda, or other solvent, and the resulting mass is steam heated. Casein may be made into a plastic mass with an aqueous solution of borax, the excess water removed, and a sufficiency of elastic nitrocellulose may then be added, and the whole kneaded into a homogeneous mass.—Henry Percy Gormanston Steedman, 84, Ebury Street, London, S.W.

New Materials.

Boomerang Envelopes.—Messrs. Houghtons have just introduced a very convenient pattern of envelope for the sending and return of proofs. The envelope has a transparent window and contains an enclosure sheet, on one side of which the photographer's name and address are printed. The sitter therefore has only to reverse this sheet when returning the proofs; unsealed, the proofs are transmitted at the penny postal rate. The price per 1,000 of the envelopes, inclusive of printing name and address, are: £3 1s. in 7¼ x 5¼ size; and £4 1s. in 9 x 7 size

Negative Papers.—As a less expensive substitute for glass dry-plates, negative paper has always had its supporters, and though the ratio of economy remains about the same, the inducement to use this form of sensitive material appears to be greater at the present time. MM. Guilleminot have recently introduced a negative paper under the name "Folio-Brom. Guilleminot," the film of which strips off after drying, yielding a thin transparent negative. This material is evidently of high quality, and certainly removes the objection of greater time in printing inevitable with the ordinary negative paper. Folio-Brom is sold at the rate of 3s. 3d. per dozen half-plate sheets by M Jules de Gottal, 17, Cecil Mansion, Marius Road, London, S.W.17. We have also received a very similar product (except that it is non-stripping), viz., Brantom negative paper, from Mr. B. A. Coppez, 24, Cross Street, Hatton Garden, London, E.C.1. This is a very good example of the ordinary negative paper, and is supplied at the rate of 3s. per dozen half-plate pieces.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

News and Notes.

Messrs. Ilford, Ltd., announce that their works will be closed from Monday, August 15, to Saturday, August 20. They will therefore esteem it a favour if customers will kindly anticipate their requirements for that period, in order to avoid disappointment.

Ultra-Violet Rays.—M. L. P. Clerc asks us to remedy an omission to carry out a correction of the proof of the paragraph in his "Paris Notes" of July 15 last, on sensitive materials for ultra-violet rays. In line 2, col. 1, p. 418, the correct reading should be:—with æsculine dissolved in glycerine, or with some brands of machine oil having naturally a blue fluorescence.

Action of Light on Water-Colours.—Valuable water-colour paintings have, on the advice of the director of the National Gallery, been removed from the Crystal Palace War Museum during the summer months, the director reporting possible injury because of "excessive light owing to the glass roof." Those of our readers who have water-colours framed and hanging in their studios will, no doubt, take warning, and remove them to a place less brilliantly lighted until the arrival of autumn.

A Link with the Past.—Last Saturday's papers announced the death of Mr. Alexander J. Wilson, at the age of 81 years. Mr. A. J. Wilson, who was a well-known London financial expert and journalist, and the author of several works on financial and commercial subjects, was the son of George W. Wilson, founder of the well-known Aberdeen view publishing firm, who, the papers say, was "H.M. Photographer for Scotland," and "the first man to photograph Queen Victoria." Mr. George Wilson died in March, 1893.

Portrait Styles.—The writer of the "Star's" "Tea-time Gossip" column writes:—"There is a growing tendency amongst women who like to be photographed for the benefit of the general public to appear as incongruous as possible. They clothe themselves in gorgeous evening gowns, and then pose for the photograph that is to amuse the multitude, with a background of rural scenery, usually including a sundial and a pond. Apparently they see nothing strange in reclining on the grass in a brocaded evening gown—and they are not the new rich, either."

Bird's-eye View of the Isle of Wight.—We are told of a remarkable and complete "air view" of the Isle of Wight, which has been taken by a Farnborough member of the Royal Air Force. The operator used what he termed an aviator's camera, and made the exposures at a height of 3,000 feet. A report states that the view "clearly shows the busy streets of the towns and villages on the island at practically one time," whatever that may mean. The airman-photographer left Farnborough during the morning and returned for lunch, "the time taken to complete the return journey, including the taking of the photographs, was ninety-five minutes."

Mr. F. C. Tilney, we are informed, has severed his connection with the "Amateur Photographer," to which for more than twenty years (previously under its title of "Photography") he has been a regular contributor on art subjects, and in which of late he has been the writer of the weekly criticism of photographs reproduced as supplements to our contemporary. During the past year or so, Mr. Tilney has been identified with a movement for individual training in a knowledge of the fine arts, and it is to be presumed that the claims of this latter upon his time have determined the discontinuance of his regular writings for photographers in the Press.

Are English People Becoming Better Looking?—Had photography been discovered two or three centuries ago the task of physiognomists would have been very much easier than it is to-day (writes a correspondent). Anyway, British types of faces are changing, Prof. Sir Arthur Keith, seems to suggest in his annual report on the museum of the Royal College of Surgeons, of which he is curator. He has charge of the most representative collection of human remains and specimens in the British Empire, perhaps in the whole world. So great has it grown that a classification, just started, will take several years. From the evidence accumulating under his hands Sir Arthur Keith has become convinced that definite changes, particularly in the face and jaws,

have been taking place in a large proportion of the British people during the last century or two. The date at which these changes took place the professor does not indicate. He considers that their exact nature and extent can be determined only by a systematic study of ample material. The change believed to be taking place in the British type of face is due to an alteration in the palate, and there are differences noticeable in the formation of the upper jaw. Whether this means that we are becoming more handsome or otherwise is an interesting problem which future research will show.

THE WELSH SALON.—At a joint meeting, held at Cardiff on Saturday last, it was decided to hold the Welsh Salon of Photography organised by the Wales and Monmouthshire Federation of Photographic Societies either during the last fortnight in November or the first in December, as best suits the Cardiff City Hall Museum authorities, whose assistance is expected in the exhibition. The latter fortnight is preferred by the Federation, as by December the Welsh exhibitors' prints from the Royal Photographic Society's Salon will be available for inclusion in the exhibition. The Federation is dropping the open salon rule this year and reverting to five distinct classes. These include classes for survey and scientific camera workers, and also for the beginner in pictorial photography.

PHOTOGRAPHING THE CRETONNE GIRL.

To the Editors.

Gentlemen,—In the vernacular of the bus conductor and taxi-driver, photographers are now "fairly up against it." Designers of modern dress materials and wall-papers, jazz and futurist artists, with a host of fellow conspirators, have plotted together to so clothe the female form divine in multi-patterned myriad-coloured fabrics that were intended to defeat the camera. The season's raid of bizarre frocks which has been sprung upon us, however, has given many an average professional studio worker a very rude shock, and many conservative and old-fashioned operators who have in the past scorned the use of isochromatic and panchromatic plates are now inquiring the price of them and worrying about their use.

Subdued colouring and sanity of design appear to be as rare at our seaside resorts as the sea-serpent, the piers and promenades being filled with flappers and sedate spinsters clothed more or less in garments of hectic hue and daring design mostly reminiscent of "the morning after the night before," combined with a Brock's benefit. And the cretonne craze is spreading, causing many of us to dread the coming of Bank Holiday crowds, and men, who really ought to know better, have been seen with cretonne ties and handkerchiefs

Refusal to photograph a cretonne-clad creature, as some of the hot-heads have suggested as a reprisal, would never do, since it means a loss of business. The use of an "ordinary" plate, as others suggest, is an equally bad proposal; the result such a plate would give is, in the majority of cases, as unsatisfactory to the photographer as the sitter. The most surprising results are sometimes obtained when an ordinary plate is used, results which picture the original as being quite a different article.

Colour-sensitive plate and filter experts could no doubt name at sight the proper plate and filter to use to give the best monochromatic rendering of a given cretonne dress, but what would suit one costume might not serve for another, designs and colours being so numerous.

Then there are the questions of likeness and exposure to consider. One cannot play about with screens, plates and exposures when taking a portrait, as one may do when taking a negative of a dress with no lady inside it. The likeness in some cases, but certainly not in all, is quite as important as the correct rendering of the dress, and one cannot always sacrifice an artistically-lighted portrait head for a dress, however tempestuous, jazzy, or zoological the design may be. The obvious remedy is to "give and take," to get as much light and shade on the face, and, incidentally, as good a portrait as possible, at the same time screening the plate only enough to allow of a comfortable exposure.

It would be an act of folly to "go for" the dress and lose the likeness, as it would also be to secure the likeness and lose the dress Better to lose a little on each than much upon one. The difficulty of securing an absolutely perfect rendering of both may with safety be explained to the sitter.

The most successful photographer of the modern cretonne girl the writer has met with is in favour of an unscreened panchromatic plate, or a self-screen plate with a light or medium yellow filter added, with a tendency to favour the latter. Non-filter and self-screen isochromatic plates used with added light-filters give the most surprising and useful results, and deserve to be more largely used than they are at the moment. Much, of course, depends upon the predominating colours in the cretonnes, and no hard and fast rules can be laid down; the operator must use his judgment, and visualise to the best of his ability how the colours—particularly the blues, greens and yellows—will be pictured by a screened or unscreened self-screen plate. This plan of working will take a lot of beating if one keeps an eye on the blues and adds the right filter to master them

GODFREY WILSON.

AMERICA'S FIRST "MOVIE SHOW."

To the Editors.

Gentlemen,—A day or two before Mr. W. Friese Greene's death in May last the New York "Tribune" gave an account of America's first cinematograph show, and the now almost-forgotten man who engineered it. His name is C. Francis Jenkins, and the date of the show was June 6, 1894.

Mr. Jenkins, we are told, was a clerk in the Treasury at Washington, who was interested in photography and the lantern; he worked hard on what the historian calls "animal locomotion" and with plates, but it was not until films came along that he progressed. His first picture was of a vaudeville dancer named Annabelle doing a skirt or butterfly dance in a backyard.

All we are told up to the present is that he got a satisfactory picture, and that he went to his home, Richmond, Ind., to exhibit it to his friends, travelling the whole distance of 720 miles on his bicycle.

The home of a cousin, who kept a jeweller's shop, was selected for the show. The only electricity available was a trolley-wire passing the door, and using a pail of water as a rheostat, he made the necessary connections. Invited in were his parents, with a few friends, including the editor of a local paper.

The story of the show as given by the "Tribune" is distinctly American in style. It tells how his parents were not told what they were to see, how surprised they were, particularly the ladies, when they witnessed the "wicked" dancer's rather daring gyrations and movements of the skirt.

However, Jenkins was a hero, and the machine is—or was a few days ago—in the National Museum at Washington.

The first public show for which there was a charge for admission was at Atlanta, Ga., in the spring of 1895, but it was a huge failure. Jenkins sold his interest in the invention for 2,500 dollars, and that was all he got. Those of your readers who are interested in the matter will find further particulars of Jenkins and his show in the "Literary Digest," dated April 30, 1921. This publication, I believe, is more easily referred to in your libraries than the "Tribune."

It is, indeed, a curious coincidence that the Americans should be calling attention to their pioneer at the very same time the English newspapers were directing attention to Mr. W. Friese Greene.—Faithfully yours,

J. W. DICKERSON.

Washington

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

K. P.—Potass carbonate and carbonate of potash are the same thing. "Potasche" in the German formula evidently denotes caustic potash.

P. W.—A good cleaning preparation for prints showing stress marks is:—Borax, ½ oz.; water, 30 oz.; methylated spirit, 5 ozs.; rubbed over with soft rag or cotton wool.

GAMMA.—We are afraid there would not be a sufficient demand to justify the reprinting of the recent H. and D. articles in book form. The issues are, however, still in print with our publishers, price 5d. each, post free.

N. W.—Our advice is not to buy until you have seen that the lens will do what you want. The instruments of this name are not by a maker of the first rank, and it is not safe to assume that each one comes up to a standard.

MANSFIELD.—On the whole, it is not worth while to make up hypo in stock solution of saturated strength. A solution containing 1 oz. of hypo in every 2 ozs. (fluid) is strong enough and convenient in use. It is very quickly made by dissolving 1 lb. of hypo in (hot) water and adding water to a 32-oz. mark on the bottle.

N. E.—The gum-bichromate process had its day for pictorial purposes from about 1894-1904. In the volumes of the "Amateur Photographer" of these years you will find many papers on it by M. Demachy and others. The oil process introduced by Mr. G. E. H. Rawlins in 1904 turned the control pictorialists into a new channel.

EXEN.—Usually if a person is susceptible to metol skin poisoning, the only thing is to discontinue the use of the developer. An ointment which is often beneficial is Sphagnol or Ujah; or Ichthyol, 10 grs.; lanoline, 40 grs.; boric acid, 40 grs.; vaseline, 30 grs.; applied two or three times a day and well rubbed in before going to bed.

M. R. E.—For bleaching out bromide or gaslight prints which have been outlined in Indian ink, there is no better mixture than the iodine-cyanide reducer. Solution of mercury bichloride as used for intensifying is nearly as good. If you want a less poisonous solution than these, there is: Thiocarbarmide, 240 grs.; nitric acid, 4 drs. (fluid); water, 20 ozs.

E. S. N.—In the U.S. (uniform system) of stops, *f*/4 is taken as the unit, and is marked 1. Smaller stops are given numbers which indicate the required number of times of exposure compared with *f*/4, *e.g.*, *f*/8 is 4, *f*/16 is 16, *f*/32 is 64. The system has never been generally used by English opticians; in fact, it has practically been applied only to the lenses of Kodak cameras.

T. F.—We really think it is too late in the day to expect a great demand for a printing paper of this kind. Surely you realise that in this country, at any rate, the bulk of printing material sold is of the development type. If the qualities you name are realised, there would no doubt be a demand, but we think it would be a select one, not on a scale to justify the plans you appear to entertain.

D. B.—We should not care to use the potash carbonate method of drying for negatives which are to be kept, unless washed again; otherwise, it is a quite satisfactory process. You can economise in spirit considerably by seeing that negatives drain thoroughly from the spirit; and it is also economical to use two baths in succession, discarding the first after a time. The water which collects in the spirit can be largely extracted with potass carbonate.

S. E.—It makes no difference to the photographer's ownership of the copyright that the family now order and pay for prints. It is evident from what you say that the copyright was originally the property of the photographer, and in the absence of a definite assignment of it to somebody else, it remains his copyright. The mere act of supplying copies is not such assignment. We are quite sure that if you were to copy any of the prints you would render yourself liable to action for infringement by the original photographer.

M. E.—Woodburytype is an obsolete photo-mechanical process. Messrs. Waterlow and Sons, we think, were the last to work it commercially in this country. A lead mould (made from a gelatine relief from the negative) forms the printing surface. The "ink" is a warm solution of gelatine, containing pigment, printing consisting in taking casts (in this gelatine mixture) from the mould. The results were exceedingly good; their chief defect was the "cirtiness" of pure high lights, such as skies. The process was chiefly used for portraits.

F. MEYNELL.—A 9-inch *f*/4.5 lens on your quarter-plate hand camera, even if you can manage to fix it on the front, will be a white elephant, unless you are prepared either to stop down or work with the camera on a tripod. In any case, depth of focus is so small that the opportunities for using it effectively are comparatively few—portraits and figure studies. We think you will do better by enlarging the negatives taken with your 6-in. lens. If you wish to have a lens of longer focus there is no need for the maximum aperture to be greater than *f*/8 or, at and rate, *f*/8.

H.D.—(1) For an 8-ft. picture of the 1-inch dimension of the film at 60 ft. throw you require a lens of approximately 8 inches focal length. Your 115 mm. lens is, of course, only just over 4 inches. (2) For projection behind the screen you could get your 8-ft. picture at 20 ft. throw with a 2½ inch lens. So far as the angle of projection is concerned there is no disadvantage in this, but the brilliancy of projection through a screen is a good deal less than by projection *on* to a solidly surfaced screen. (3) As regards the colour and stereo processes, particulars of patents announced as applied for are not available until the complete specification is published, which may be not until a year, or longer. We are afraid it is impossible to say from the meagre particulars whether your process is worth following up, but although we do not want to be discouraging, it is right to say that the chances of commercial success are against an inventor who has not very powerful backing in the way of trade influence and resources. At any rate, we think you had better do nothing until you have taken out provisional patent protection for it, which you can do at the cost of about £1.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3196. Vol. LXVIII. FRIDAY, AUGUST 5. 1921. Price Fourpence.

Contents.

SUMMARY

Detailed instruction in the many purely mechanical precautions required in the making of light-filters is given in an article by Mr. C. Smyth. This relates to the choosing and testing of the glass, and its cutting and edging; to the preparation and stripping of the gelatine films, and to the cementing of the cover-glasses. (P. 459.)

The first portion of the review by Mr. Raymond E. Crowther of photographic progress during 1920, compiled for the Annual Report of the Society of Chemical Industry, will be found on page 461.

In a leading article we have some hints to give on the clear rendering of distance in landscapes when using both ordinary and telephoto lenses. (P. 458.)

At the Croydon Camera Club, Mr. E. A. Salt recounted his experience with the new universal developer D.50. (P. 466.)

A patent by a Chinese inventor provides for the use of wide-angle lenses on reflex cameras. (P. 466.)

For the accurate masking of lantern slides by means of single strips the accessory described by Mr. D. Charles in a note on page 463 will be found of great service.

The uses of cork-lino in the printing and mounting room, the renovation of studio stands, and the improvement of the developing sink are the subjects of "Assistants' Notes." (P. 463.)

In alteration of premises carried out for the purpose of erecting a daylight studio it is important to see that full light from the sky actually reaches all the glazed area of the studio. (P. 458.)

Changes in town views by the erection of statues, such as that of George Washington in Trafalgar Square, provide the occasion for the making of fresh negatives as a means of keeping view postcards saleable. (P. 457.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a communication, MM. Lumière and A. Seyewetz describe their experiments on the development of Autochrome plates after desensitising. They find that aurantia is a desensitiser which allows of the plates being handled in a moderate yellow light, and which has the further advantage of permitting of a time method of development within fairly wide limits of exposure. (P. 29.)

Mr. E. J. Wall contributes a résumé of methods of making reliefs for colour transparencies and prints by processes other than those depending on the action of light on bichromated gelatine, etc. (P. 30.)

By means of a recently invented taking camera, the Prizma process of colour cinematography is now being employed for the production of a photo-play in colours under ordinary conditions of production. (P. 32.)

Further improvements in the Traube copper-mordant process of dye-toning have been patented. (P. 32.)

Brief details of improvements in the Christensen process of making colour screen-plates are given on page 32.

EX CATHEDRA.

Interesting the Sitter. It is said of Sir Joshua Reynolds that he always wished that he could dine with a man before painting a portrait of him. Whether this be true or not, it is a fact that many of his finest pictures were of sitters with whom he was well acquainted. The portrait photographer is in a less fortunate position than the painter, for he has often only the opportunity to study his sitter for as many minutes as the latter has hours. If, however, these few minutes are judiciously employed it will be found easy to get a fair summing up, not only of the appearance, but the character of the sitter. Most people, especially men, are somewhat ill at ease when facing the photographer; whose aim it should be to remove this feeling and bring out their true nature. We have seen a well-known barrister enter the studio wearing his sternest "court" expression, which might do very well for a daily paper reporting a trial, but which would not be acceptable to his family and friends. But after a couple of minutes quite another expression was obtained by raising some non-legal point of interest. A copy of the current "Who's Who" is a useful reference book in a studio to which sitters of standing may come, as it gives a clue to the tastes and recreations of a vast number of people. The right subject is touched at once, and the sitter is flattered at the idea that the photographer knows all about him.

* * *

Keeping Local Views Saleable. Makers and publishers of picture postcards and other forms of views would do well to keep a sharp eye on such productions, as many little things happen to alter the topographical truthfulness of a view and so spoil the market for it. Sometimes the changes are trivial and perhaps unnoticed by the photographer and casual visitor, but small as a change in a view may be it will serve to date a negative, and cause a print to be rejected. For instance, a statue was recently added to the more or less satisfactory collection on view in and around Trafalgar Square—a statue of George Washington—thus making the thousands of existing postcard views of one corner of the Square out of date. Views of the St. Martin's Church corner of Trafalgar Square taken before June 30 last will probably be sold in their thousands for many years to come, as many purchasers will not notice the statue's absence, but American trippers will be on the look-out for it, and will no doubt reject views not showing their national hero. It therefore behoves all publishers of postcards to see that their views of the National Gallery and Square are up-to-date. An over-sanguine reader of our pages, whose place of business overlooks the Square, expected to see some hundreds of photographers at work for some days after the unveiling of the statue, but has not seen one. He tells us that an enterprising Continental firm of postcard publishers he could name would have had operators

at work within a few hours, had the statue been in Paris, and hundreds of new and up-to-date views in the dealers' shops the next day.

* * *

Skylight Construction. When erecting or altering a room which is to be used as a daylight studio, it is very necessary to see that all the glass which is put in provides effective illumination. In some of our American contemporaries are advertised ready-made skylights for inserting into existing roofs, so as to convert them into "single slant" studios, and the advertisements show them as being notched into a building leaving the original roof higher than the glass at both ends. There is no objection to this arrangement provided that a sufficient run of glass is provided, but as we were recently in a studio in which from the sitter's end two rows of glass were more or less obscured by the upstanding angle of the original flat roof, we think it desirable to draw attention to this contingency. The operator was quite unaware of the disadvantage until it was demonstrated to him that the opening of the end blind admitted practically no light which could reach the sitter directly, although there was certainly an increase on diffused light. The moral is that with a notched-in studio in which an effective 10-ft. run of glass is wanted, at least 2 ft. more should be allowed in the skylight.

DISTANCE AND TELEPHOTOGRAPHY.

Let us hasten to disclaim any intention to treat distance in this article from the artistic standpoint. We shall not stoop to say anything about distance lending enchantment to a view, and are not in any way concerned with the cunning and deliberate representation of comparatively near objects, so as to create an impression of remoteness. Even that idea of distance which depends upon the obstructive or dispersive influence of the atmosphere, and is comprehended by the term "aerial perspective," is largely outside our present purpose. What we have in view is the actual photographic reproduction of actually distant objects, and the technical difficulties which such reproduction involves. As regards the question of exposure, probably the plan of giving to a distant landscape a quarter the exposure which one would give to a landscape with a strong foreground satisfactorily covers the majority of cases. But distant seascapes and distant snow-clad hills need only half the exposure required for most distant landscapes, and not infrequently less than half. If there is any foreground in either case the problem may, as we all know, become complicated, and failure may be caused by an attempted compromise between exposing for the shadows and letting the lights take care of themselves—most venerable of rules at which some iconoclasts are now throwing stones—and *vice versâ*. Several years ago the Hydra plate did in effect get over this difficulty, but the method did not prove popular, and the plates are no longer, we believe, commercially obtainable.

But exposure is not by any means the only, or indeed the most formidable, difficulty in connection with the photographic rendering of distant objects. It is quite possible to give an absolutely correct exposure on an ordinary plate, and yet to obtain a representation of distance which is entirely unsatisfactory, simply because such a plate records no difference between pale blue and white. When the orthochromatic or panchromatic plate is used without a filter improvement begins, and with a filter it continues, until truly remarkable results are attained, not only in differentiating blue distances from the sky, but also in reducing the effect of the intervening atmosphere. Short of the condition technically known as "boiling," which defies every effort to cope with it, haze in a distant landscape presents very little difficulty to the photographer properly equipped with filters and suitable plates. But the filters need to be much stronger than those commonly used, in which the multiplying factor is only, say, from four to seven. In the field equipment of the printing companies of the Royal Engineers during the war 40-times filters were used with excellent results. Sometimes even a light fog can be neutralised by a red filter employed, of course, in conjunction with a panchromatic plate. The whole question of the application of filters to the rendering of distance is a most interesting one which can hardly be said as yet to have been studied with any degree of finality.

There are distances and distances, and, when only a soft and vague rendering is desired, an ordinary lens in conjunction with a deep filter will frequently meet all requirements, more especially as in such cases it is generally necessary to include middle distances or foregrounds. When detail in the distance is desired, recourse must be had to the telephoto lens, precisely as in ordinary vision the aid of the telescope has to be called in to bring distant objects nearer. If the telephoto lens were regarded purely as a photographic telescope its function would be more universally understood, and in many cases its practical application to the everyday purposes of photography would be simplified. But the telephoto lens has the important advantage that, while there are some people who cannot, or will not, learn how to use a telescope properly, the sensitive plate is just as ready to record a telephotographic as an ordinary photographic impression, provided that certain simple precautions have been taken. Except where the magnification is very low, as with the popular single-focus tele-lens, a hood is necessary to prevent internal reflections, and in the great majority of cases the intelligent employment of light-filters produces vastly improved results.

In connection with exposure a difficulty arises in telephotography which is apt to be overlooked. Calculations are generally made on the basis of the exposure which would be given if an ordinary lens were used, this being multiplied by the square of the magnification, and due allowance made for distance. But it sometimes occurs that the latter allowance is wholly superfluous, the action of the telephoto lens having brought distant objects so near, that in place of blue remoteness we have what is to all intents and purposes an ordinary landscape with a strong foreground. These, it is true, are somewhat extreme cases, but when they arise they must be cautiously dealt with, the appearance of the picture on the focussing-screen being a more trustworthy guide than any arithmetical or mechanical method of computation.

It is not, perhaps, sufficiently clearly realised that at this period of the year a great deal of good and interesting instantaneous telephotography can be done without the help of fast single-focus lenses, if fairly distant objects are selected, and the fullest advantage taken of favourable light-conditions. At the sea-side, for instance, pictures of yachts at a considerable distance from the shore can be telephotographed at quite respectable magnifications, even if a filter be used, while records of bathing scenes, bright and amusing, without being vulgar, can be unobtrusively secured from piers, using a fast positive and a telephoto attachment giving a magnification of x 4 or x 5. Best of all, groups of happy children playing on the sands can frequently be instantaneously telephotographed with results far more

satisfying than those achieved in the average holiday snapshot. In such cases, while the "distance" may be actually very near, the interval between camera and object is sufficiently long to produce that happy unconsciousness on the part of those photographed, which we all want to see exhibited in the pictures of celebrities in our illustrated Press. But that, one fears, is at present a very distant view.

THE MECHANICS OF LIGHT-FILTER MAKING.

As a general rule light-filters are best bought, not made, but there are many who take a pride in making their own apparatus quite independently of any saving in cost, though this feature must always make a certain appeal. It is not suggested that the manufacture of one or two small light-filters can be effected in most cases more cheaply than by buying them, but cases not infrequently arise when home-made filters save the pockets very appreciably.

From time to time much information has been published in various journals relating to the spectral qualities of the various aniline dyes employed in filter making, and precise formulæ for coating have been given in past numbers of the "B. J." The reader is directed to coat a certain area of glass with a definite weight of dye incorporated with a stated quantity of gelatine solution, but the mechanical side is usually left severely alone, or but briefly alluded to. Yet the mechanical aspect is of the utmost importance with light-filters employed in front of, or just behind the lens if its optical properties are not to be impaired.

With the exception of a few remarks regarding the general characteristics which dyes must possess to render them suitable for filter making, only the mechanical side will be dealt with by the writer who has had a long and practical experience. It consists in the selection and cleaning of the glass used for the temporary and the final support for the dyed gelatine pellicle, stripping the film, and cementing and drying the finished article.

The Dyes.

Dyes for filter making fall into two broad classes—those suitable for "compensating" or "correcting" filters, and those adapted for "selective" filters. In the former type, familiar to all photographers, the dyes used must have a gradual absorption, subduing or damping down the actinic light (to which the plate is most sensitive) to an intensity that allows the less actinic light to adequately record itself within the period of correct exposure for the more actinic rays. Complete, or partial correction can be obtained in this way, dependent upon the degree of sensitiveness of the plate to the spectrum, and the spectral qualities of the light-filter. The dye must not cut off any portions of the spectrum entirely, but only damp them down to such a degree that they are recorded in their correct visual luminosity. Too sharp a cut, say, of the violet and blue results in these colours being rendered as unnaturally dark. On the other hand, too sharp a cut is not possible with "selective" filters, which demand the minimum absorption in the transmission region, the ideal aimed at being the complete cutting off of certain portions of the spectrum, and the passing of the remainder in full intensity.

Optical Conditions.

In addition to the correct spectral qualities of the dyes, the following conditions are essential for the production of filters to be used in front of, or immediately behind the lens.*

(*a*) The glass must be flat, and have both sides parallel.

(*b*) It must be free from strain, air-bells, and scratches.

(*c*) The coloured gelatine must be transparent, of even density, and free from dust, etc.

(*d*) The filter must be mounted so that no pressure is applied to it, and be sufficiently large not to obstruct marginal rays.

* Tricolour filters must also have the same focal-length, give the same size image, and be of identical thickness.

If the filter is placed close to the focal-plane parallelism is not of so much consequence, but the presence of scratches or dust is then even more objectionable. If used outside the lens system, as over the slit of a spectroscope, the only essential is correct absorption.

Selecting the Glass.

The best glass to choose is known in the trade as "extra-white patent," or "parallel-plate," though for many purposes the cheaper "patent plate-glass" may be used, though it has smaller areas of flatness, and is somewhat green in colour. For the highest class filters optically worked "flats" are employed, which should not be thinner than ¼ in. to avoid any tendency to buckle in cementing. For all ordinary work glass 1/16 in. thick will be serviceable for filters up to 2 ins. square or in diameter; for larger sizes slightly thicker is preferable.

To test for flatness the well-known expedient of holding the glass at an angle of 45 deg. to the cross-bars of a window and observing the reflections from the front and back surfaces is satisfactory. Still better, as a test object is a thick cord stretched taut. The glass is moved about so that its whole surface is tested. If the two images keep the same distance apart the glass is flat, divergence, or convergence, indicates the contrary. Mark the flat parts with a piece of dry soap cut to a point, which if free from grit will never scratch the surface. Apart from flatness, any portions which show air-bells or scratches should be rejected.

A perfectly regular divergence or convergence indicates the glass to be wedge-shape. By selecting two glasses exhibiting the same error in equal degree, it is possible to compensate for their departure from flatness by so mounting them that one error neutralises the other, but the selection of flat portions is to be preferred.

Cutting and Edging.

If only a comparatively small area of glass is being dealt with the simplest way of cutting it into squares is to lay on a flat surface some squared paper, as a guide, marked to the size, or sizes, required, and on top the glass; cutting may be done either with a diamond or good wheel-cutter, the latter being more liable to produce fine splinters. A flat rule or straight-edge is applied to the guide marks, with the necessary allowance for the clearance between the straight-edge and the cutting surface of the diamond or wheel-cutter. An allowance of about 1/32 in. is also made for the subsequent grinding. All cuts in one direction are made first, the glass is then turned over, again adjusted to the guide marks, and the cuts at right-angles executed. Then, and not before, break apart. In commercial work special boards are, of course, employed.

The edges now require to be smoothed, which for squares is an easy operation. A piece of fine emery cloth is glued to a flat board, or a length of flat iron has some fine emery or carborundum powder sprinkled on. Using a small quantity of turpentine as a lubricant, the glass is worked up and down the surface with long and steady strokes, taking care to *first* remove the sharp edges by bevelling them. This is effected by holding the glass at an angle of about 45 deg., and is a precaution which should never be neglected, as it prevents chipping.

Circles of glass are usually cut with a special apparatus which gives the glass a circular movement under a stationary diamond. They can only be edged satisfactorily by a circular stone of fine grit. "Craigleith," or manufactured stones are generally employed. Use steady pressure and keep the glass moving in the opposite direction to that of the stone. Care

is necessary to avoid flat places and facets. Several same size circles can be edged in this way in one operation if they are stuck together with paraffin wax.

Glass squares can be fashioned to circles, but some practice is required. The square is first roughly shaped with "glass-shanks," and then ground to fit a circular ring. For an occasional job discs of metal or other material stuck on the glass will furnish the necessary guides. The observations as bevelling squares apply equally to the edging of circles.

When edged, wash in warm soda solution, wipe with soft cloth, and polish with fine tissue paper damped in alcohol. In pre-war days good quality methylated spirit was employed; much of the present-day spirit may be unsuitable.

Throughout all operations, great care should be taken not to scratch the glass, splinters of glass on the cutting board being a fruitful source of trouble.

The Gelatine Film.

Many will prefer to purchase the spectroscopically tested dyed gelatine obtainable at comparatively modest prices, but if its manufacture is undertaken the actual glass used for the filter should never be coated with the dyed gelatine solution. In the first place, the pull on drying is considerable; so much so, that even thick plate-glass may be distorted, and in the second place, the gelatine coating in the centre will be perceptibly thicker than at the margins owing to its drying there first.

In the following instructions it is assumed that the requisite dyes are incorporated together, and therefore only one piece of gelatine will require cementing. It may be candidly admitted that making the gelatine pellicle and stripping it certainly does require care, but if the directions given are carefully followed success is assured, provided the operator is not "all fingers and thumbs."

The Temporary Support.

Thick plate-glass is employed as the temporary support, and it is essential that the surface to be coated be absolutely clean. The glass is placed in boiling water and allowed to soak for a short time, and then rubbed over with a soft brush to thoroughly loosen any adhering dirt or grease. Remove the glass, and pour on the surface to be coated boiling water from a kettle, drain off, and, before quite dry polish with clean tissue paper and wrap in clean paper. When the glass has cooled down sprinkle on a few drops of benzole, and again polish with clean tissue paper until not a suspicion of smear remains. If coating is not immediately to be proceeded with two glasses should be so treated and placed, polished sides in contact, in clean paper.

It may here be remarked that if the glass is well cleaned and polished it is not necessary to wash it again after the gelatine film has been stripped. Any adhering gelatine at the edges is removed, and the glass re-polished with the benzole. Should, however, the gelatine film after stripping show any signs of being smeary, a repetition of the washing procedure is required.

Coating and Stripping.

The plate-glass, polished side up, is placed on a slab and levelled. If the slab be level in the first instance this alone should not be relied upon, for the glass may be somewhat uneven. Stout and squat legs of "Plasticine" placed underneath the slab (as first suggested by Mr. J. W. Purkis, who prefers four legs, not three) afford a ready means of adjustment. For the occasional worker, coating glass larger than whole-plate is not recommended.

With the glass slightly warm and perfectly level, the hot dyed solution is carefully poured on the centre, when it will readily flow over the surface and take up its own level. The amount of gelatine solution usually given for a certain area is such that whilst flowing to the edges it will not overflow.

When the coating is perfectly dry, it and its support are placed vertically about 2 ft. above a bowl of steaming water for about four minutes. A sharp knife is then quickly run round the edges of the gelatine, when, if the glass has been properly cleaned, the gelatine film should strip readily, and require nothing in the nature of hard pulling. If resistance is met with, more steaming is wanted. On the other hand, if the gelatine is found to be soft and elastic from over-damping, it is put aside for a few minutes and tested again for stripping. The stripped film is placed between tissue paper, and when quite dry examined for any uneven edges which are cut out, and the pellicle stored between stout cardboard.

Cementing.

Having selected a piece of the dyed gelatine free from dust specks, hair, etc., it is placed between the two glasses, and trimmed round with a sharp knife. The film is then ready for cementing. Canada balsam dissolved in xylol is recommended, as it flows better than when chloroform or ether is used as the solvent. The right consistency is about that of golden syrup, not thicker.

Having placed the component parts of the filter on a piece of waste paper supported on a level surface, lift the top glass and gelatine film with the left hand, and from a broad-mouth pipette pour on enough balsam in the centre of the glass on the paper to about cover one-fifth the surface, and at once drop the film on to it. No attempt at this stage should be made to distribute the balsam. A similar pool of balsam is immediately poured on the gelatine, and the remaining glass lowered on to it. Central pressure by a finger will now force the balsam, and any airbells formed, out towards the edges. As much balsam as possible should be squeezed out, and the edges wiped before putting the filter aside to dry.

Drying and Cleaning.

Quick drying by heat is always to be avoided, as it dries the balsam at the edges rapidly, and usually causes distortion. Three weeks should be allowed, the filter being kept in a warm room. Neither can placing the filter under a weight be recommended, though if the filter is on a level surface and the pressure applied is moderate and uniform, there is no theoretical objection. A practical one is that the filter more often than not sticks to both support and weight.

The best plan to adopt is to rest the filter on some wooden slips cut to triangular section and supported in a level position by a tray of some sort. This allows any balsam that may ooze out to run clear of the filter and drop on the tray. When the three weeks have nearly expired if much balsam is seen to protrude it may be gently scraped away. Finally, the filter is cleaned with methylated spirits and a soft cloth, and polished with alcohol or good quality methylated and tissue paper. To employ a stronger solvent, such as benzole, is dangerous, as if any were to run between the glasses the balsam might be attacked and star, when the work would all have to be done over again.

A word of warning may also be given against the use of binding strips, which are prone to cause distortion. The neatest way of finishing is to black the edges with a black celluloid varnish or paint. Varnishes containing turpentine, or other solvent capable of dissolving the balsam, are, of course, inadmissible. After polishing, and thus edging, the filter should be tested for flatness in the same way as suggested for its component glasses.

Mounting.

Filters should never be placed in cells or holders that are liable to exercise undue or uneven pressure on the edges, as distortion will inevitably result. The performance of many a high-class filter has been ruined by a clamping ring screwed up too tightly. A clamping ring should always have a shoulder so adjusted that when the ring is screwed home the filter is only *just* held with no tendency to rattle. A point occasionally overlooked is that the filter must be sufficiently large not to cut off marginal rays of the lens. Thick flats require more allowance in this respect than filters of lesser substance.

C. Smyth.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[The fifth annual volume of reports upon progress in the various branches of chemical manufacture, issued by the Society of Chemical Industry, includes, as did the preceding issues, a report on photographic materials and processes. This is again by Mr. R. E. Crowther, A.I.C., who (writing early in the present year) reviews the literature, published during the year 1920, representing original contributions to the technical improvement of processes of making negatives and positive prints, orthochromatics and colour photography, cinematography and photo-mechanical processes, and also the methods of research and measurement which are generally described as "sensitometry." Inasmuch as these reports are, so to speak, a series of annual stocktakings of what has been done during the twelve months preceding the issue of the volume, we have naturally wished to give them a place in our pages, since no other publication of the year so well reviews what has been done in reference to the current state of knowledge. As regards the references to original sources of publication, it should be explained that the contraction "J" denotes the fortnightly "Journal" of the Society of Chemical Industry in which are published abstracts of the chief papers relating to photography from the chemical standpoint.—EDS. "B.J."]

THE now famous Sankey judgment[1] on the legality of confiscation of a consignment of pyrogallic acid has been responsible for the appearance, during the past year, of foreign competitive materials of "key" characteristics, on the market in this country. The consumer has temporarily benefited from this competition, but the manufacturers who had, under the protection afforded by war conditions, achieved commendable success in the manufacture of products never before made in this country, have been confronted with a set of conditions which, unless radically modified, will undoubtedly strangle their efforts to build up an industry capable of joining in world-wide competition later. Against a country which, previous to the war, enjoyed a virtual monopoly in most of the fine chemicals used in photography and which at present has the advantage of an abnormally low rate of exchange, it could not be rationally expected that anything but disaster would overtake the new home industries under the conditions of open imports. When it is recollected that photographic fine chemicals are in many cases intermediates in the dye manufacturing industry, which has also suffered greatly in consequence of the Sankey judgment, the reason for the very noticeable fall in the amount of British manufactures on the photographic market is not far to seek.

Of the developers, *p*-aminophenol, metol, amidol, and monomet are still being made in this country, and the manufacture of quinol (hydroquinone) has recently been commenced. Some new matter connected with the preparation of pyrogallol[2], [3] and of quinol[4] has been published, and W. J. van Sicklen[5] claims to have prepared metol free from all tendency to cause skin trouble. This important question of skin attack is one which might well be considered by a Research Association; there are undoubtedly other factors to be taken into account than personal idiosyncrasy, and it is probable that a very small amount of some specific impurity, resulting from the method of manufacture, is the cause of the trouble.

p-Aminosalicylic acid, under the name of "Neol," has been placed on the market by J. Hauff and Co., who claim that in conjunction with a caustic alkali, it will correct the undesirable effects of gross over-exposure to a greater degree than other rapid developers. The correction is attributed to pronounced tanning powers of the substance formed by reaction with the light product in the film. Luppo Cramer, however,[6] expresses doubts both as to any specific corrective action and on the theory propounded. As far as other chemicals are concerned, there has been a marked tendency towards a reduction in prices, more particularly perhaps in the case of bromides. Of the base materials, paper of suitable quality has been more and more difficult to procure. The quality of that most readily procurable leaves much to be desired. Even when well isolated from the emulsion in the process of manufacture, considerable deterioration of the emulsion has been frequently met with. The materials used in the wrapping and the method of packing usually employed, in which the face and back of alternate sheets are in contact, are frequently responsible for the failure to "keep" on storing. The deterioration is most apparent when sulphide-toned prints are produced, although in many cases even two or three months' storage effects deterioration which can be observed in ordinary black-and-white developed prints—a state of affairs which only resulted after prolonged storage of pre-war material under indifferent conditions. The recovery of the silver from exhausted fixing baths has been the subject of some discussion in the photographic press,[7] but no suggestion of the use of a salt other than "hypo" as the fixing agent has been forthcoming in order to facilitate the electrolytic recovery of silver in the metallic state. F. F. Renwick[8] has called attention to the practicability of a solution of potassium cyanide for the fixing of gelatine emulsions, and it should be worth while investigating the electrical recovery of the silver from exhausted baths of this salt. As was to be anticipated, the abnormally high price of silver was not long maintained, and no work on its replacement by less expensive metals has appeared. The process of photography devised by K. Wilcke,[9] although it employs no light-sensitive silver compound, can scarcely be considered of practical importance. It is of theoretical interest, however, as affording another instance of the application of the characteristic property of selenium of decreasing in its electrical resistance when illuminated. Attempts have been made in the past to utilise this property in the construction of photometers, but without much success. Recent improvements in the manufacture of light-sensitive cells indicate that experimentation with the new materials would give interesting and probably successful results, leading to the construction of an instrument which would entirely eliminate the personal factor.

Negative Processes.

The properties of gelatine are receiving the attention which the importance of this product demands, and, as a result, the chemical rôle of this amphoteric colloid is becoming more and more apparent. D. J. Lloyd,[10] in publishing experimental evidence of the amphoteric nature of gelatine, expresses the opinion that gelatine consists of a solid framework of neutral gelatine (only stable at its iso-electric point, p_H=4.6 at 20 deg. C) which is insoluble in cold water, containing some combined water, and an interstitial fluid which is a solution of a gelatine salt.

T. R. Briggs and E. M. C. Hieber[11] have studied the phenomenon of the liquefaction and gelatinisation of gelatine by salts, and conclude that the processes are strictly reversible. Luppo-Cramer[12] offers a satisfactory explanation of some hitherto obscure features of development by reference also to the chemical department of gelatine. The idea that gelatine acts only as a protective colloid, allowing of the formation of relatively large and sensitive grains or crystals in the preparation of emulsions, and physically inhibiting the action of developing solutions on the unexposed areas of the film, will have to be abandoned in view of the work which has been pub-

lished during the past year.[13] The physical properties of gelatine cannot be disregarded with impunity, however, and the turbidimeter described by S. E. Sheppard[14] should prove useful in any photographic laboratory.

Development.

The action of developers on the latent image has been the subject of some considerable amount of study. B. Homolka,[15] continuing his work on the isomerism of developers (in this instance, the polyhydroxybenzoic acids), and taking into consideration the dissociation constants of the hydroxybenzoic acids, concludes that the failure of gallic and protocatechuic acids to function as developers is attributable to anhydride condensation between the OH group of the carboxylic radicle and the H of the OH situated in the para position. It is pointed out that the anhydride of the former acid can be regarded as a derivative of resorcinol and the latter as a derivative of phenol, neither of which substances functions as a developer. If the disposition of the side-chains or their constitution is such that anhydride condensation yields a derivative of an *o*-dihydroxy compound, or is prevented, developing properties are exhibited. Thus, pyrogallolcarboxylic acid (COOH : OH : OH : OH = 1 : 2 : 3 : 4) and the ethyl esters of gallic acid and of protocatechuic acid, will all develop the latent image. The reactivity of the sodium salt of cyclohexane-1.4-diol-1.2.4-trisulphonic acid as a developer[16] is of interest, since it necessitates a re-statement of the theory enunciated by Homolka and already referred to.[17]. A general survey of the mechanism of development is given in a communication by S. S. Sheppard and G. Meer,[18] who, reasoning by analogy from the proved adsorption of dyes by freshly precipitated silver bromide, conclude that the Lainer effect, *i.e.*, the acceleration of development resulting from the treatment of an exposed plate with dilute potassium iodide solution, and which is chiefly noticed when organic developers of low eduction potential (*e.g.*, quinol) are used, is due to increased adsorption and complex formation as between silver halide and developer. A fogging action of dilute potassium iodide solution on silver bromide emulsions is recorded in the same communication, and is ascribed to nucleus infection of the grains.

A. H. Nietz[19] has conducted an inquiry into the development potentials of the organic developers. A new and valuable method of determining these potentials was worked out and the following conclusions were arrived at:—"The effect of bromide on a developer depends upon its reduction potential. If a developer is of low potential, a given amount of bromide will have a larger effect in lowering the density than it will if the developer has a high potential. . . . . Maximum contrast . . . . . is not correlated with reduction potential. No definite relation can be shown to exist between the time of appearance and the reduction potential, neither does the fogging power of a developer depend upon its potential." Figures are given which show that the aminophenols are the most energetic, the hydroxyphenols next, and the amines the least. Both nuclear and side-chain (in the amino group) methylation increases the energy. Introduction of a second amino group greatly increases the energy, whilst change to a glycine and the introdnetion of a $-CH_2OH$ group lower the energy. Evidence was found that fog is practically absent from the high densities and increased as the image density decreased.

Lüppo-Cramer is responsible for the publication of much valuable matter relative to development reactions. In addition to the explanation of the developing power of aqueous solutions of amidol and similar compounds already referred to[12]—an explanation which assumes reaction of the gelatine with the salt-forming acid of the developing compound, with consequent liberation of the active free base—he has thrown light on the phenomena of "depth" development, and the desensitising action of developing solutions[20]; the study of the latter action has led to the discovery of a practical method of developing even highly colour-sensitive plates by inspection, in bright yellow light.[21] It is only necessary to treat the exposed plate for one minute in the dark with a 1:2000 solution of phenosafranine. The desensitisation effected by such treatment is of such an order that thereafter the plate can be handled without any risk of fog in light sufficiently actinic to fog rapidly wet "slow" bromide paper. The action of the phenosafranine appears to be entirely chemical, since a film of gelatine dyed under the same conditions transmits the entire visible spectrum; any colour-screening action of the dye is thus precluded. Moreover, Lüppo-Cramer has been able to demonstrate that the free amino groups contained in the dye play an important part in the reaction.[22] The marked acceleration of the action of the slower developers resulting from the desensitisation treatment affords further evidence of the chemical nature of the process, as does also the fact that the printing-out sensitiveness is enhanced as the desensitisation to latent image formation becomes more pronounced. Altogether the subject appears to be of great importance, both practically and theoretically, and promises to lead to a clearer understanding of the mechanism of sensitisation. The accelerative effect of increasing amounts of sodium sulphite in amidol developing solutions is attributed by Abribat[23] to reciprocal catalytic action of the sulphite in the oxidation of amidol, other oxidation catalysts producing a similar effect. Exactly what proportion of the acceleration caused by the sodium sulphite is attributable to this catalysis is difficult to judge, in view of the fact that increase in the sodium sulphite concentration leads to increase in the basicity of the amidol, a fact which would alone account for most of the observed acceleration. A general review of the organic developers is given by A. Seyewetz,[24] who repeats the statement that the developing properties are raised to a maximum by the introduction of a nuclear methyl group in the ortho position to the hydroxyl group, a statement which does not agree with the results obtained by Nietz,[19] who quotes a reduction potential of 7 (quinol=1) for *p*-amino-*o*-cresol and 9 for p-amino-*m*-cresol. The tendency of repeatedly used developing solutions to produce dichroic fog has been found by L. Lobel[25] to be due to the accumulation of colloidal silver in the solution. The conditions of low carbonate concentration with high sulphite concentration favour the formation of colloidal silver, and it was found that an addition of 20 per cent. sodium sulphate causes flocculation of the silver, which can be readily filtered off. Simultaneous development and fixation of photographic images has been further investigated by A. and L. Lumière and A. Seyewetz.[26] These workers confirm the previous conclusions of C. Otsuki and T. Sudzuki, and suggest a combination of chloranol and caustic alkali, or of metoquinone and tribasic sodium phosphate as practical formulæ. The process is particularly recommended for the treatment of over-exposed images. Identification of the products resulting from development reactions appears to be receiving no attention. Workers in this branch of research will be interested in the results of W. Eller and K. Koch,[27] who find that the dark brown substances formed by the action of air on phenols, *e.g.*, catechol and quinol, are identical with the humic acids, which are found amongst the decomposition products of vegetable organisms and of certain sugars.

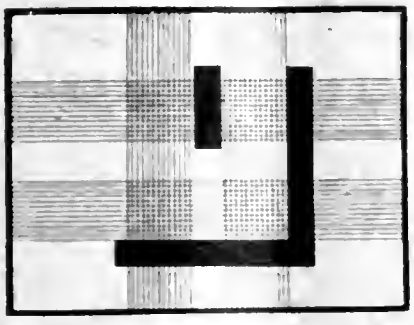
MASKING LANTERN-SLIDES.

Many devices have been introduced with the object of avoiding the use of stock masks and of treating each subject individually. The little piece of apparatus illustrated was made to assist in this, and is employed in connection with "masking strips" of plain black paper cut to a variety of widths, but of a uniform length of three and one-eighth inches. Such strips are marketed already gummed as one of the "Specialist" series of lantern-slide accessories, but whether these are used, or whether the operator prefers to cut his own, I recommend that the adhesive should be wetted or applied, as the case may be, only on the extreme margin of the slide where the binding will subsequently cover it. Such little points as these may not make any difference from the exhibitor's point of view, but do assist in creating a "finished" or "professional" appearance to one's products when examined in the hand.

The purpose of the device shown in the cut is to make the application of the black strips an easy and rapid process, and to get the finished subject masked squarely with just the same ease as though one were trimming it as a print. It consists of a couple



of waste whole-plate negatives, one of which is first soaked in iodine or other bleaching solution till white, and then rinsed and fixed out in hypo. The other may be treated either in the same way or may be cleaned off, as it is merely to act as a cover-glass. The first one, when washed and dried, is ruled on with drawing ink in the manner shown. To ensure the maximum accuracy of the lines the plate is pinned down to a drawing board with one long edge against a fixed ruler, and the lines drawn in with the aid of set-square and parallel ruler. When dry the cover-glass is bound on with gummed strips, and then two strips of thin card are glued on the outside of the glass to act as registration stops or carrier for the slides to be masked. These strips are shown in solid black in the illustration. The black patch in the centre represents merely a bit of paper stuck on the glass. The reason for putting this on is that there is a tendency when a slide has been masked on this device to find that it shows a slight reluctance to be lifted off owing to suction between the two glass surfaces. This is a hindrance to rapid work when one is busy, and only a very thin bit of paper will prevent any trouble of this sort.

The method of using the masking guide requires only the briefest, if any, description. It is supported in a retouching-desk or on the top of a printing-box, and the slides are slipped one at a time against the cardboard strips. Two or three spots of fish-glue are applied to one edge of the slide (or water in the case of the ready-gummed variety), and a strip is laid on to suit that side of the subject, immediately adjusting it on or parallel to one of the black lines on the guide underneath. Naturally, one cannot trouble to find a strip of the exact width for each side, so one uses pieces a little too wide in every case. All four sides are masked in the same way in rapid succession, and then the slide is laid aside to dry. As soon as the pile of slides is finished the superfluous paper is trimmed off, preferably by the use of a long pair of scissors, such as paper hangers use. The slides are then fed into plate-racks and placed in a hot place, say over a gas-stove for thorough dessication of both slide and mask, and while still warm each slide is dusted with a brush and is laid flat with a previously cleaned and dusted cover-glass upon it. This procedure prevents the re-absorption of moisture before the final binding up.

D. Charles

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

A Makeshift Acid-Fixer.

A passably good acid-fixer, particularly suitable for negatives, may be made according to the following formula:—Water, 20 ozs.: hypo, 4 ozs.; soda sulphite, ½ oz.; citric or tartaric acid, 150 grs. The proper method of mixing the above is to dissolve the sulphite in 2 ozs. of water, the citric or tartaric acid in 1 oz. of water, and mix the two solutions. Next dissolve the hypo in water to make 17 ozs., and when quite dissolved add to it the acid sulphite mixture slowly and with constant stirring. Made in this way, the bath keeps and acts well, and has, I believe, no harmful chemical action, negatives being clear and good and keeping well.—L. T. W.

Improving the Developing Sink.

Earthenware and lead-lined developing sinks are not very kind to porcelain dishes, glass measures, and negatives, when the latter are accidentally dropped or brought too suddenly in contact with them. False bottoms of wooden laths are commonly used in such sinks, but an old, or even a new, india-rubber mat is very much better and much more safe. Rubber mats with small holes, such as are commonly used in motor cars, are the things to use, and the more completely such a mat covers the hard bottom of the sink the better. The holes are small enough to prevent measures of an average size slipping through, and the rubber forms an excellent cushion-like base for dishes on which they may be rocked with little or no "clatter," while the holes in the mat permit of easy removal of dishes. The rubber is also soft enough to prevent breakages should a negative be dropped upon it. The rubber mat will last for a generation and will not be affected by most chemicals. Another useful dodge is to fit rubber heels—old or new, revolving or otherwise—to the four corners of the bottom of large wooden dishes used on an earthenware sink.—L. T. W.

Renovating Studio Stands.

It is said that all trades have their closely-guarded secrets, and I cannot help thinking that the use of Vandyke brown ground in water is a secret of painters and decorators, for there is nothing like it, nor anything so cheap, for the renovation or redecoration of wooden studio camera stands, doors, and other things needing a walnut finish. No cleaning off of old paint is required. The article is simply wiped down with weak soda water, say one eggcupful to ½ gal. of warm water. Then procure two- or three-penny worth of Vandyke brown ground in water from any paint store and mix with water—or, better still, stale beer or stout—to form a very thin paint, and apply to the wood work with a brush or sponge in the usual way, brushing straight, stippling or dabbing, as may be required to get a desired effect. When quite dry varnish with copal varnish. Should the Vandyke not yield the exact tone desired other colours may be blended with it—burnt umber to darken or raw sienna to lighten. These colours, however, like the Vandyke, must be purchased ground in water, colours in dry powder form not serving. The cost of the Vandyke need hardly be considered because of its cheapness—less than threepenny worth serving for a large door—but the varnish is at the moment rather expensive. The work must be varnished in order to set and make perfect the colour, the unvarnished Vandyke rubbing off easily.—P. R. S.

Cork Lino in the Workroom

Some odd pieces of rather good quality cork lino, left over from covering the floors of some of the more important offices in a certain establishment, found their way (by means that need not be made public) into the photographic department, where they were promptly made use of.

The largest pieces were fastened on to the fronts of the copying and enlarging cases by coating the latter with thin glue well worked up to a froth and rolling the lino well and finally tacking round the edge with lino-brads. After a year's use pins are just as easily stuck in and pulled out, and there are no signs of per-

manent holes; a new coat of white paint on the enlarging easel saves the cost of many sheets of white paper for focusing upon.

Smaller pieces of the linoleum were used for cleaning backs of negatives and lantern-slides. The surface affords just enough grip to prevent the film slipping and becoming scratched, while the absorbent nature of the cork soaks up any superfluous moisture and so prevents the cleaning mixture running underneath and getting on the film. The smooth level surface allows plates to be laid face down and cleaned with a proper amount of pressure, and is a far easier and safer method than doing it while holding the plate in the hand.

One piece found its way into the mounting-room. Primarily it is used as a pad for stroking prints and to lay them upon while attaching the adhesive tissue. On occasion its resilient nature affords a means of securing adhesion when portions of a multiple mount have not been properly stuck. It is merely placed under the mounted print in the press and a long pressure given. In the case of a print or tints of rather unusual thickness the whole is laid face downwards, and the surface of the soft lino forms a temporary counterpart, as it were, to the projections of the various papers, and permits of pressure being exerted on each surface.—X.N.

Studio Feminities.

It is often a difficult problem to screen off a corrider, reception room, or dressing room window having an ugly view (as so many windows on photographic premises have in industrial centres) without a loss of light. Many of the new rippled or wavy, or even starred and frosted glasses may, of course, be used, but it is not always convenient to re-glaze a window, and interior work of some kind is called for. I have covered my employer's small windows very successfully by putting a light curtain of finest sheer white linen, held by narrow brass rods at top and bottom. At the lower end of the linen screen are inserted some large motifs of fillet lace placed in an artistic pattern. The fine white linen excludes a sight of the ugly roofs and chimney pots and allows plenty of light to enter, and its whiteness seems to enliven the whole place, while the arrangement of the lace takes away any effect of severity plain white linen may have.—A Lady Operator.

FORTHCOMING EXHIBITIONS.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

Sooty Studio Lights.—Photographers who have studios in London, and who complain of falling soot obstructing their light, will be interested to know that London is far from being the sootiest place in England, and the records of the Meteorological Office place the distinction on Liverpool, where during January alone there were 26.03 tons of dirt deposited on every square kilometre. Kingston-upon-Hull came next with 20.24, and Newcastle-upon-Tyne showed a deposit of 18.35 tons. The dirtiest neighbourhood in London is Southwark Park, which totalled 16.91 tons a square kilometre. Some parts of the metropolis were astonishingly clean; Finsbury Park, for example, was only one-third as dirty as Southwark. Golden Lane and Wandsworth Common showed 14 and 12 tons deposit respectively. It should be understood that these were only totals for one month, but in the following months the statistics bear approximately relative proportions. Glasgow is a much cleaner place above ground than London, but Birmingham is distinctly bad, and, with the exception of Southwark, showed a much higher percentage of "sootiness" than London.

Photo-Mechanical Notes.

Chromo-Litho Screen Negatives.

According to a patent specification, No. 146,143 (open to inspection before acceptance), of M. L. Bassani, Neuilly-sur-Seine, France, the following method is used for making the screen negatives for chromo-litho or similar printing processes: In making one of the negatives, the screen is shifted along the lens axis, and in making the second negative the screen is displaced both axially and transversely, the two movements being preferably made simultaneously.

Bitumen Printing.

A recent patent specification, No. 139,472, granted to F. Hausleiter, 5, Lefèvre Strasse, Friedenau, Berlin, describes a process of bitumen printing in which a coating of bitumen is applied to a dyed negative gelatine image.

A picture is produced by printing or exposure in the camera, for example on a glass plate coated with gelatine sensitised by a haloid silver salt. For a half-tone picture a screen is used. The negative is developed with a developer which enables the gelatine of the undeveloped parts to be washed off with hot water. When this has been done the gelatine is coloured with a substance opaque to all light-rays acting on bitumen. This is essential if the silver deposit is not very dense, inasmuch as, according to Eder, bitumen is sensitive to the whole of the visible spectrum. The plate is then coated on the image side by pouring bitumen over it, and is exposed from the back. The bitumen is thus rendered insoluble at the parts not screened by the gelatine. The bitumen picture is developed in the ordinary way, and the gelatine is removed by a solvent. A positive bitumen picture is thus produced, well adapted to be etched. The free access of air to the bitumen during the exposure renders the same very uniform, even with pictures of large size.

The following patents have been applied for :—

Colour Photogravure.—No. 12,178. Rotary multi-colour photogravure printing machines. W. Pickup.

Printing.—No. 12,387. Photo-mechanical printing. A. R. Trist.

Lithographic Transfer.—No. 12,616. Preparation and treatment of photographic ferric films for lithographic transfer purposes. H. L. Shawcross.

Rotary Photogravure.—No. 15,299. Rotary intaglio or photogravure printing machines. T. R. Johnston.

Printing Screens.—No. 16,008. Methods for production of screens for photo-mechanical printing. A. R. Trist.

Process Screen.—No. 18,346. Photo process screen and method of preparing same. J. A. H. Hatt.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 18 to 23 :—

View Finders.—No. 19,641. Photographic view finders. C. W. Beevor and A. E. Cooke.

Photographs.—No. 19,842. Taking photographs. O. von Bronk.

Daylight Development.—No. 19,364. Daylight development apparatus for flat films. J. Worms.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Lenses for Reflex Cameras.—No. 162,829 (February 13, 1920). In the use of a reflex camera it is usual to open the lens aperture to the full during focussing, and watching the ground glass

before taking the photograph, and then to close the iris diaphragm immediately before taking the picture. This necessitates a considerable delay between the time at which the camera is focussed, and the time at which the actual exposure is made, because it is necessary to examine the graduations in order to see that the aperture is reduced by the correct amount. The invention is designed to provide rapid setting of the working aperture.

Upon the revolving portion of the lens mount which actuates the diaphragm is placed an adjustable handle, and on the fixed

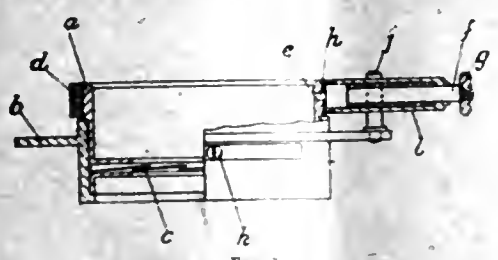


Fig. 1.

portion of the lens is placed a stop which limits the motion of this handle in one direction. The method of use is then as follows:—

Having determined the aperture at which the photograph will be taken, the diaphragm is set to that aperture. The adjustable handle is then moved until it is in contact with the stop on the fixed portion of the lens mount. The table handle is then clamped so that it is no longer adjustable as regards that portion of the lens mount which actuates the iris diaphragm, but is attached to it. The diaphragm can now be operated by means of this handle, but only within limits such that one end of the travel is when the aperture of the lens is fully opened, and the other end is when it is closed to the pre-determined aperture for exposure. The diaphragm can then be set to give either of these two positions by feel without examining the graduations, and the photographer having focussed and arranged his picture with the full aperture of the lens, can close it down without shifting the position of the camera to the aperture at which he requires to take the photograph.

In the drawings, the ring *a* revolving in the main flange portion of the mount *b* actuates the iris diaphragm *c*. The method employed for fitting *a* and *b* together is a fine screw thread, on

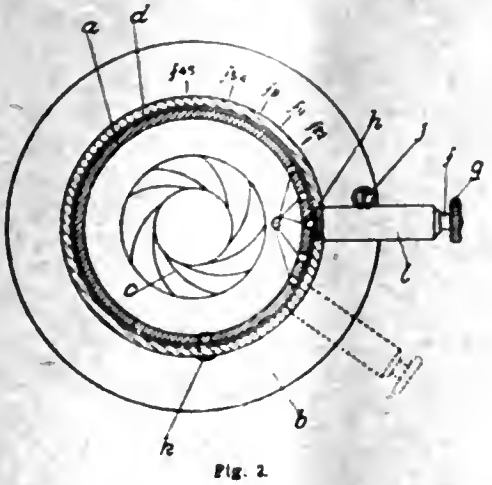

Fig. 2.

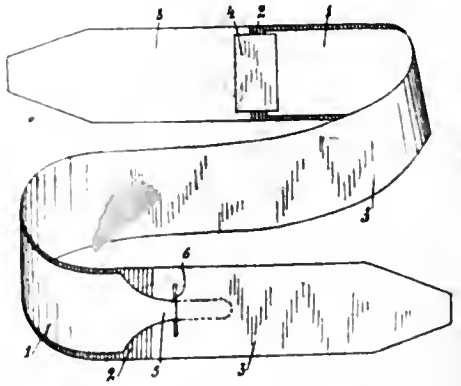
which *a* will turn with reference to *b*. Revolving on the ring *a* is a ring *d*, to which is attached a handle *l*. Within the handle *l* is a spring plunger *f*, at one end of which is a milled knob *y*, and at the other end of which is a stud *h*, which engages in holes *e* in the ring *a*, and fixes ring *d* to the ring *a* in various positions according to the positions of the hole *e*.

On the outside of the ring *d* an indicator or arrow is engraved which reads against a scale on the flange portion of the mount *b*, which is so arranged that when it is set to any of the divisions on the flange *b* the spring plunger *f* will drop into a hole in the ring *a* and fix the ring *d* with its handle to the ring *a* in a series of different positions corresponding to the divisions on the flange *b*.

On the flange *b* is fixed a stud *j* against which the handle *l* is stopped in its travel in one direction. It is stopped in its travel in the other direction by a permanent stop *k*, in such a position that the aperture of the lens is fully open. The result of this arrangement is that by pushing the handle in one direction the iris diaphragm of the lens is always open to its full aperture, but by pushing it in the other direction the diaphragm is closed to differing amounts, according to which of the holes *e* the handle (by means of the spring stud *h*) is in engagement with.—Conrad Beck, 68, Cornhill, London, E.C.

Roll-film Spools.—No. 163,913 (May 21, 1920). The end of the film is removably attached to its protective wrapper by a tongue on it passing through a lateral slot in the wrapper. This tongue is permitted to slide freely in the slot to allow of the displacement of the film relatively to its wrapper whilst at the same time securing sufficient relative fixity between the film and the wrapper to prevent the film being drawn with the paper when they are wound on the reel of the developing apparatus. The adherence of the tongue to the paper is also increased by the



tendency which the material of the film has to wind up on itself.

The tongue may also take the form of a label, on which particulars of the exposure may be written.

The film 1 is shown wrapped with its back against the black surface 2 of its protective wrapper, which is coated with a sheet of red paper 3. The ends of the wrapper extend beyond the film to enable them to be fixed to the reels or bobbins. The end of the film 1 is stuck to the protective wrapper by means of a gummed label 4 whilst the final extremity forms a tongue 5 which is inserted freely in a slot 6 in the protective wrapper.

After the film has been exposed, inscriptions for the identification of the film may be made on the back of the tongue 5, by unwinding, with precaution, the film until the back of the tongue appears.—W. P. Thompson, 12 Church Street, Liverpool, for L. Gevaert & Co., Vieux Dieux, Antwerp.

Reflex Cameras. — No. 161,736 (January 29, 1920). The invention aims to permit of the use of a wide angle lens with the least possible disturbance as far as the ordinary parts are concerned, and with minimum change in the shape, size and appearance of the camera.

The casing of the camera, 10, is provided at one side with a vertically slotted opening, 12. This partition is slotted similarly to the camera casing at its side next to the camera slot, 12, and is grooved internally around its other three sides, so as to provide for the reception of a ground-glass, in a frame or a plate-holder.

In this way the lens may be brought into close proximity with the sensitive plate, and a wide angle lens may thereby be effectively utilised.

The casing of the camera, 10, carries a hinged cover, 19, which normally closes the slot, 12, and it is thus obvious that the invention will not interfere with the ordinary use of the camera, but will simply supplement its action and increase its range of use.

The image is focussed on the ground-glass through the open rear end of the casing with the mirror raised and therefore a

lens shutter as distinguished from a focal plane shutter is required for the wide angle lens.- Kung-Cho Chen, 75, Baikal Road, Shanghai, China.

The following specifications are open to inspection before acceptance.

REPRODUCTIONS.—No. 166,513. Methods and devices for the photographic reproduction of pictures represented on curved surfaces. G. von Lücken.

APPARATUS. — No. 166,524. Photographic apparatus. W. Feuerzeug.

CROYDON CAMERA CLUB.

LAST week Mr. E. A. Salt brought the new developer D 50 to the attention of members. It is, he said, one of the many products of the Cooper Laboratory, established in 1904, and originally used by the founder, Mr. W. F. Cooper, for technical research, but since the war the manufacture of fine chemicals, among other things, has been undertaken.

D 50 is a two-solution developer, the A solution being supplied in concentrated form. The B solution contains the usual sulphite and soda carbonate (to which ¼ grain of potass. bromide per ounce of mixed developer is added), and is made up by the user, but the ingredients will shortly be on the market in tablet form.

Personally he never mixed the sulphite with the carbonate, as the preservative often deteriorates rapidly in alkaline solution, but dissolved each separately in half the quantity of water prescribed for the B solution, neutralising the sulphite with one-eighth its weight of potass. metabisulphite, as first suggested by their late member, Mr. C. Welborne Piper. Stored in well-stoppered bottles, the sulphite keeps for a very long time, and, when required for use, the solutions are mixed in equal parts, and form the B solution.

D 50 is considered to hold a medium position between high and low reduction developers, and it is alleged that, compared with other developers, less exposure can be given. Its lasting properties in concentrated solution appear to be remarkable, the makers stating that the developer will keep indefinitely without losing its developing power. They also mention that some solution made up in March, 1920, is still perfectly good. The origin of the rather distinctive name arose out of the fact that a number of developers had been tested in the laboratory and studio, and the developer, numbered 50 for identification, was finally selected. The big "D" stands for "Developer," and not the "other thing," despite a strong sulphurous smell when the bottle is opened.

It is, he said, claimed for D 50 that it presents the most universal developer ever placed on the market, and "owes its unique properties not alone to the careful blending of certain standard forms of reducing agents, but principally to the incorporation of agents *new to science*," a wording which a vendor of a hair-restorer might well envy. Considering that a 4-oz. bottle, making 160 ozs. of mixed developer, is priced at 4s. retail, it may seem somewhat expensive when compared with pyro. To the worker who only develops a plate or two at long intervals, this, of couse, is so, but here the added cost is not worth mentioning. On the other hand, considering its universal application and undoubted capacity for developing plate after plate, or print after print, D 50 may prove to be very economical to the busy operator.

In a eulogistic article in a recent number of the "B.J.," Mr. John H. Gear recorded that six whole-plate negatives had been developed with only 5 ozs. of the developer, the last negative being equal to the first in every respect. He also stated that tests extending over months had demonstrated the developer to be first-rate for bromide and gaslight papers. The same article also recorded a distinct difference of opinion between the author and Dr. Adolphe Abrahams as to whether a strong or weak developer was best for under-exposed plates. In his, the speaker's opinion, the matter might well be settled between them one evening at the R.P.S. with 8-oz. gloves. It would undoubtedly be the fixture of the session.

A test made in the short time at his disposal certainly illustrated the remarkable staying-power of the latest comer. Twelve half-plate bromide prints were developed at irregular intervals over a period of five days with 3 ozs. of developer, the last print 45 hours after the one preceding it. The former showed a deposit inclining to olive-green (quite suitable for some subjects), but the remainder were of a good black tone, which warmed a trifle towards the end. Each print was immersed in water till limp, drained, developed, washed for half-a-minute, and fixed in hypo solution, to which a little neutralised sulphite had been added. It remained water-white throughout. If a batch of prints is developed one after the other in a relatively small amount of solution, a shade more exposure seems desirable for the last, to compensate, in some measure, for the waning power of the developer. With correctly exposed prints the period of "full development" is clearly indicated by the growth of the picture ceasing.

Mr. Gear had stated that "the negative is free from colour, yet, if desired, the density of that given by pyro can be easily produced," a statement which throws little light on the printing value of the deposit. As all photographers know, the deposit of a non-stained pyro-developed negative affords by inspection a good idea of its printing value, whilst the blue-black and transparent deposit of a metol-developed negative prints far flatter than it looks. He had only developed one dry-plate with D 50—a "fine grain ordinary," exposed in the camera to a contrasty negative, but of good quality. The exposure was very full, the developer diluted to half-strength, when the colour of the resulting positive proved to be a fine olive-black, closely resembling a pyro-developed plate, but, perhaps, more transparent. The gradation was all that could be desired, but this, he thought, was more a function of subject, plate, exposure, and period of development, than any inherent quality in the developer.

In the discussion, the president, Mr. J. Keane, said he had given D 50 a good trial, and was very pleased with it; the negatives were admirably adapted for enlarging. Mr. Harpur spoke on many things, lapsing occasionally into the subject of the evening. D 50, in his opinion, scored chiefly by the ability to use it over and over again. Others expressed a similar view. Mr. H. W. Berry said no other developer was capable of the feat illustrated by Mr. Salt's set of bromide prints. The question arose whether the last of the batch would sulphide as well as the first, a most important point for a professional.

SURGERY ON THE FILM.—Much interest is reported by the "Times" Berlin correspondent in a new type of cinematograph apparatus exhibited privately to medical men in Berlin yesterday. Dr. Forch, in introducing the new invention, claimed that it would prove of especial value to surgeons and surgical students. It is a ball-shaped apparatus, which can be fitted to the ceiling of the operating theatre and set in motion from below. While an operation is being performed it enables films to be taken showing the minutest details of the operation. At yesterday's exhibition films were displayed showing the course of various amputations, the removal of an appendix, the sewing up of a broken kneecap, the breaking open of abscesses, and, finally, an operation on a child for wryneck. After the exhibition, it was announced that the Government was considering establishing a technical cinematograph institute in Berlin, and a special lectureship in cinematography at the Charlottenburg High School.

News and Notes.

HURTER-DRIFFIELD MEMORIAL LECTURE.—On the invitation of the Hurter and Driffield Memorial Committee, Dr. The Svedberg will deliver the memorial lecture in 1922.

"TAKE A KODAK WITH YOU'"—Asked at Bow County Court whether defendant had been spiteful to her lately, a woman plaintiff replied: "Yes, she even photographed my new costome and got one like it the following week."

OBLIGING THE PHOTOGRAPHERS.—At the test match played at Manchester last week, the captains of the English and Australian teams tossed twice for choice of innings. The first toss was official, the second one was to oblige the Press photographers, who were not ready with their cameras for the first spinning of the coin.

BARGAINS IN FRAMES, ETC.—Consequent upon rebuilding and extension of their works, and to avoid expense of removing stock to temporary premises, Messrs. J. Epstein & Co., Rupert Street, Bristol, are offering some exceptional bargains in frames and mouldings, cardboards, etc. Application to the above address will bring particulars.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—In consequence of the recent industrial trouble, the annual meeting of the Society cannot be held just yet, since many members are on holiday, and those in the seaside resorts are kept busy. The President has decided to postpone the holding of the annual meeting until the month of September, when members in Blackpool will be free to make arrangements for the holding of this meeting.

HIGH ART—AND JINKS—IN SYDNEY.—The Australian papers just to hand contain particulars and programme of a "Soft Focus Evening," arranged by the Sydney Camera Circle. There was "song, music, laughter, eats, drinks, and smokes," the whole affair being run on the lines of the "Salon Smokers" of pre-war days. A very happy evening was spent, and, at the end, an "extra turn" was suggested, namely, "Has anybody here seen Tilney?" by Messrs. Paton and Wakeford. "What on earth has dear old Tilney been doing?" asks a correspondent, who sends us particulars of the social evening.

IDEAL HOMES EXHIBITION.—An interesting feature of the Ideal Homes Exhibition, to be held in Glasgow from September 19 to October 8, will be the Photographic Section. The arrangements have now been made for the classification of the different competitions. There will be five sections in all. The first will deal with landscape and seascape, the second portraiture and figure studies, the third architecture, the fourth any subject, and the fifth will be devoted entirely to amateurs. With the exception of class 5, the prizes will be: 1st £10 10s., 2nd £5 5s., and the 3rd £3 3s. For classes 1, 2, and 3, one print in each mount will be asked for, while in class 4 three prints on each mount, ½-plate and under are desired. In class 5, which is for amateurs only, this has been divided into three sections, A, B, and C. A is for six contact prints illustrating a happy holiday, B for any subject, C for landscape or seascape. Valuable prizes will be offered for the amateur competition. The Photographic section is under the auspices of the Scottish Photographic Federation.

Correspondence.

PHOTOGRAPHY FOR THE NEWSPAPERS.

To the Editors.

Gentlemen,—By way of minor comment on the very excellent articles by Mr. Vining, may I mention one feature of my experience in press photography for the possible encouragement of some tyros.

Many photographers who send photographs to newspapers, and who are unfortunate enough not to have them used in the next issue of the paper, usually grumble and write letters asking for their immediate return. This is excusable enough when the submitted prints are of current interest, but when they are not of the latter variety it is a mistake to ask for their return.

Most of the pictures I have had reproduced in the Press have been of the genre type, or, say, of the "pretty-pretty" and "Kiss Mamma" school, and it is my usual custom not to ask for their return. Editors like to have a few things "up their sleeve," and I like to know that their files or "In Abeyance" drawers contain a fair number of my prints.

One never knows what may turn up, and I have had several strokes of luck by working on this plan. For instance, seven or eight years ago there was a big fire in a pretty country village I once photographed, and I at once sent pictures of the village, but missed the market. Last year, however, to my surprise, three of the pictures were used simply to illustrate pretty corners of England, but had I worried or asked for their return they would never have been published.

Your readers must have many pictures that editors would be glad to file, pictures that might be used at any time, either as "fill ups," or when something happens to make them of particular interest. Such pictures, however, need careful selection, and some knowledge of a paper's requirements, as no editor will fill his files with pictures that will never be of the slightest use. The point I wish to make perfectly clear is that no one need worry the editor of a well-known paper to return his submitted prints unless they are of current interest. The fact that pictures are being kept proves—in the majority of cases at any rate—that there is something of interest in the prints, and that there is a chance of them being used—some day.—Yours faithfully,

FREE LANCE.

REPOLISHING OF LENSES.

To the Editors.

Gentlemen,—We have noticed with interest the editorial note in your issue of July 15, and also Mr. Lyulph Lumley's letter in the July 22 issue.

We would like to say that we have, during the past few years, undertaken the repolishing of several hundreds of high-class anastigmats of various makes, and our experience has shown us that if work of this kind is done properly, the performance of the lens is considerably improved. The rust or tarnish, which is inevitable sooner or later with all modern anastigmat lenses, if they are exposed to the influence of moisture, sudden changes of temperature, or fingered, as so many people do, always has the effect of slowing the lens, and generally gives flat, foggy negatives. In fact, a good deal of the flatness one very often sees in professional negatives is due entirely to this cause.

In repolishing lenses it is necessary to make a tool for each individual lens, so as to repolish it evenly and retain exactly the original curves. Further, no attempt must be made to remove deep scratches, as the original curves will be altered thereby, with the result that the focus, and even the definition, will be impaired.

We have occasionally had lenses brought to us with the complaint that the definition has been degraded. In several cases we have found, in the endeavour to remove the tarnish, that the lens has simply been rubbed with a polishing agent, which method has altered the curves, and consequently spoilt the definition.

Rusting and tarnishing can, of course, almost be entirely prevented by keeping the lenses clean, and not touching them with the fingers. In this connection it has often been a matter of surprise to us that more care is not taken with valuable lenses by the average professional.

All modern anastigmats are made of glass which is softer, and consequently more susceptible to bad treatment, than that of the old type of R.R. or portrait lens, and for this reason anastigmats should be treated with greater respect than was accorded to the older type of instruments.

May we say that we carried out the work for Mr. Lumley, and his experience is similar to that of many other customers for whom we have done similar work.—We are, dear Sirs, yours faithfully,

PEELING AND VAN NECK, LTD.

4 to 6 Holborn Circus, London, E.C.1.

Commercial & Legal Intelligence.

LEGAL NOTICE.—Since July 30 last H. Scott Orr, The Studio, Woodford Green, will have no further interest in the business carried on there. Any communications addressed to his agent, W. Geo. Snell, Trewithian, Westbury Lane, Buckhurst Hill, will receive attention.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. W. E.—A bromide print can be toned to yellow by a modification of the lead intensifier. Bleach the print in a mixture of lead nitrate and potassium ferricyanide as for lead intensification, but instead of darkening with sulphide, use a solution of potassium chromate, which gives a pale yellow image consisting of lead chromate. This is a very old process in making three-colour prints.

R. S.—It can be done, but it is not the satisfactory process that it is with the thin coating of emulsion on an Autochrome plate. Unless you are prepared to make the exposures on a thinly-coated plate, such as a lantern plate or one or other of the special process plates, we are quite sure that you will not find the process economical of labour. In any case it would want quite a little experience to get it into working order.

C. E. M.—If the plates have been stored in a fairly dry and cool place they may very likely be in good condition, but the bromide paper is scarcely likely to be. There is no way of remedying the defective results which the materials may give by adding anything to the developer. As regards the only possible means, namely, bathing the plates or paper in weak bichromate solutions, etc., the game is really not worth the candle.

M. W.—Unless you are soliciting business by canvassing from house to house no permit or licence is necessary, and it is not always necessary if you canvass for business in this way. In some districts the police certainly do require photographers who solicit business at people's houses to have a hawker's licence, but the practice of the police authorities in this respect varies greatly in different parts of the country. We think you can afford to ignore it unless you are pulled up by the police.

J. N. M.—It is an old idea, which you will find embodied in a device illustrated in a past Almanac. It consists of a galvanised iron pipe about 2 ft long and 8 ins. diameter, with a metal disc about 10 in. diameter soldered to each end to form a flange. The drier is screwed to the wall by one flange and an electric lamp arranged within the pipe. The heat from the lamp serves to warm about a 12-in. length of the towel, so that by moving the towel round from time to time it is kept continuously dry.

W. E. W.—Postcards or prints on double-weight paper are conveniently flattened by putting through the hot dry-mounting press, but the secret of making them *remain* flat is to first press face up (assuming the press is heated from above), then to remove from the press and at once lay face down on the still hot zinc plate. The print instantly begins to curl the reverse way, *i.e.*, the face becomes the convex side. If removed as soon as this tendency becomes evident, it will remain indefinitely in this flat condition. With a good size press, several prints can be done at once, and it takes less time than the ordinary dry-mounting.

F. N.—Pyro-metol developer is very liable to give strong negatives owing to the amount of stain occurring in the image. This developer is very little used for portraits on this account. We think you would do much better to use the ordinary pyro-soda developer given by the makers of the plates which you may be using. Generally speaking, if you mix the ordinary dish developer with three or four times its bulk of water, it will give negatives of about the right degree of strength in from 15 to 20 minutes at 60 deg. F. The development of one or two plates will show you whether you need to develop for a shorter or longer time.

F. F. E.—Some years ago at the Royal Photographic Society, Mr. R. Malby insisted on the necessity of using a panchromatic plate and suitable screen when making negatives from which slides were to be prepared and to be coloured. As compared with slides from negatives on ordinary plates, such positives were exceedingly transparent in the right places and, therefore, were susceptible of being coloured by tinting dyes to yield slides of extreme clearness and brilliancy of colour. Mr. Malby employed the aniline tinting solutions of Messrs. Johnson, applying them on the dry gelatine slide with small sable brushes and allowing one portion to dry before proceeding to colour adjacent parts.

Chas. N. Heff.—An old method of protecting carbon prints to a degree which renders them as durable as japanned goods and practically as permanent as fired enamels is as follows:—The carbon print is first mounted with glue upon a wooden panel or transferred directly to the surface of the wood. It is treated with a thin coating of chrome alum gelatine to fill any breaks in the surface. When dry it is taken into a warm room and given a coat of the best pale copal varnish. When quite dry and hard a second and third coating are given, each taking quite three days to dry. When thoroughly hard, the surface is rubbed down until quite even and free from brush marks, etc., with wet pumice powder applied with a cork rubber. Two more coats of varnish, followed by another rubbing down, should leave a perfectly even surface, which has to be polished to a mirror-like surface with rotten-stone and oil.

M. N. E.—A solution worked out some year or two ago by Messrs. Ilford, Limited, for the removal of even heavy pyro stain from negatives is the following:—

Potassium permanganate	50 grs.
Common salt	¼ oz.
Acetic acid (glacial)	1 oz.
Water to	20 ozs.

The stained negative should preferably be hardened first in a weak chrome alum solution containing one grain per ounce, unless it has been dried before the treatment is applied, as the film tends to become a little more tender in the process. The negative should then be soaked for ten minutes in the solution given above, and after a brief wash transferred to a solution of potass. metabisulphite 1 oz. in 20 ozs. of water, where it remains until the bleached image is quite white everywhere to the back of the film.

The image is then re-developed in any non-staining developer, such as hydroquinone, when a good neutral black deposit with clean shadows is produced. All the processes are performed in daylight.

SUMMARY.

In a contributed article, Mr D. Charles details the advantageous uses which can be made of gaslight paper in the copying of certain descriptions of original, and in the production of borders and masks for the addition of titles to photographs. The gaslight type of paper further serves for addition of key-letters to photographs of machines, and also for making of photographic copies which, as regards certain parts, require to be variations of the original. (P. 471.)

Mr. P. King describes the customary procedure and appliances in the development of cinematograph film, both positive and negative, and the printing of positive film by the continuous or step-by-step type of printer. (P. 474.)

In a further portion of his review of recent advancements in photographic processes, Mr. Raymond E. Crowther deals with colour sensitising and systems of colour photography, and with certain modifications in methods of producing positive prints. (P. 478.)

The value of aerial photography in making sea charts, particularly of shallow waters, has recently been emphasised in a paper by M. Volmat. (P. 483.)

The combination of two panoramic cameras with an ordinary aerial camera is described in a recent patent specification. (P. 480.)

A psychological cause of inferior output of prints is mental fag on the part of assistants regularly employed in one particular operation. We refer to this and to similar instances of mental fatigue in the printing room in an article on page 470.

A studio follow-up system for obtaining orders for portraits of children is recommended by an American professional photographer. (P. 477.)

Precautions in the use of a white background in the studio, when making either sketch or ordinary negatives, are the subject of a paragraph on page 469.

Enlarging retouched negatives, keeping flowers fresh, ferrotype developer, renewing focussing scales, and copyright in negatives are the subjects of brief replies to correspondents. (P. 484.)

Messrs. Amalgamated Photographic Manufacturers, Ltd., have announced the composition of their travelling staff in the various districts of the United Kingdom. (P. 483.)

When employing a flat-iron in the dry-mounting of prints, for example, in ordinary albums, continued cold pressure is often necessary for securing permanent adhesion. (P. 470.)

The effects, upon the permanence of the print, of using Farmer's reducer came up for discussion at the Croydon Camera Club. (P. 482.)

The advantage of dividing up the focussing screen by a series of cross-lines is experienced not only in the arrangement of landscapes, but when making copies of originals. (P. 470.)

EX CATHEDRA.

White Backgrounds. There are few studios in which a white background is not to be found, but it is not always that it is used intelligently. Many photographers find it difficult to prevent more or less veiling of their "sketch" negatives, and this can usually be traced to the flood of useless white light which is allowed to enter the camera, illuminating the bellows and woodwork, from which it is reflected upon the sensitive film. This trouble may be overcome by either of two methods. One is to have dark curtains which will cover up all parts of the background which are not to appear upon the negative; the other is to have a black cardboard mask fixed in the camera vignetter, so as to frame the subject to the desired size upon the ground glass. The latter device is the simplest, and has the additional advantage of being usable to cut off surplus light when making Rembrandt negatives. Care should be taken to keep a white background out of the way when not being used, as it acts as a powerful reflector, and causes flat results, if placed at the side or further end of the studio. It is hardly necessary to say that for sketch work the inside of the camera should have a perfectly dead-black surface.

* * *

Quality in Enlargements. It is not so very long ago that the photographer who contemplated enlarging had to pay due attention to the making of negatives exactly suited to the requirements of this particular process. Though we should be among the last to deny that for the production of perfect enlarged prints a negative of a certain character should be produced, this is the exception rather than the rule with most workers, since a negative may have to serve for several processes differing as widely in their requirements as enlarging and carbon printing. When an unsuitable negative has to be enlarged much may be done towards bringing about a passable result by a judicious selection from among the grades and varieties of bromide paper now available. In fact, if this point is given due attention, the making of perfect enlargements from negatives differing widely in character is more or less a simple matter. For an enlargement of medium size from a thin negative slow gaslight or "extra hard" bromide paper may be employed. Again, if a negative is made contrasty for P.O.P. or carbon printing, quite as satisfactory enlargement may often be obtained from it, if one of the most rapid bromide papers is chosen, a full exposure given, and the developer employed at double its usual strength. In this case, a stop bath or acid fixer is essential. Many workers do not realise what a power the different varieties of bromide papers place in their hands when enlarging from a batch of negatives of other than enlarging quality. Indeed, the excuse that used to be offered for poor enlargements by photographers, namely, that the negative was "not right for enlarging," no longer holds good.

Dry Mounting with a Flat Iron. Quite a large number of amateur photographers and not a few professional workers utilise the dry-mounting process for small prints, and in place of the ordinary dry-mounting press a domestic flat iron is employed. This is inclined to be rather too small, unless the prints are not larger than $3\frac{1}{2} \times 2\frac{1}{2}$, and it will be found worth while to obtain one of the larger heavier irons, such as are used by tailors. Another important point not often observed, is that the prints must be placed under heavy pressure immediately after being taken from under the heated iron; if this is not done the tissue may set out of perfect contact with either mount or print, in which case the print will lift within a few hours. In our experience this is the most common cause of trouble when dry-mounting in this manner. It is a good plan, after taking the print from under the iron, to place it under a heavy pile of books for an hour or two; or better still, it may be placed between the leaves of a book and pressed in an office copying press.

* * *

Ruling the Focussing Screen. Time was when nearly every photographer ruled off his focussing screen into a series of rectangles as a means of assisting the correct composition of his pictures ensuring that the principal lines and masses of the picture were placed where they make the strongest appeal. Though this plan is looked upon by some as a rather mechanical means of composing the picture, the idea is a good one, and tends to counteract the lack of balance that is often evident in out-of-door photographs, due to some principal object being placed too near the centre. The rectangular lines upon the screen entirely avoid this possibility. Some workers rule the focussing screen from corner to corner, the lines crossing at the centre. It is sometimes a great advantage to know the exact centre of the lens field, especially when very small objects are being photographed upon an enlarged scale, or when copying is being done with one of the older R.R. lenses, the definition of these instruments falling off very rapidly from the centre of the field. The centre lines allow the picture being composed so that the sharpest possible image is obtained. Of course, the lens itself must also be central.

* * *

Handling Small Film Negatives. Many professional photographers who undertake amateur work are often not aware how very delicate a film negative is even after it is dry, until some accident has occurred to its surface that might have been avoided had a little care been bestowed as the result of a warning previously given. The trade worker will certainly take care to see that no scraps of broken film from the edges are adhering to the negatives when they are pinned up to dry, and he will as far as possible try to dry celluloid films away from dust which will readily adhere to either side. But the amateur who develops his own films is not often as careful as he might be in ensuring that his negatives are free from imperfections of this kind. When these are brought in to be enlarged, no attempt should be made to get rid of dust particles, since the film is so delicate. As far as may be, such defects should be permitted in the negative and carefully worked out in the enlargement. Some workers advocate cleaning dirty films with a tuft of cotton wool moistened with methylated spirit, but we have found that with this there is serious risk of damaging or abrading the surface. Perhaps the most difficult among defects of this kind is the hard dry scum (formed by the washing water, imperfectly removed) that is often in evidence upon amateur films. If this is treated with spirit, as above suggested, there is a risk of the hard gritty particles comprising the defect abrading the film. In this case, the best way is to soak the film for an hour or so in clean water, gently rub off the scum with a piece of old chamois leather and pin up to dry.

MENTALITY IN THE PRINTING ROOM.

The best of printers will now and again turn out a batch of prints whose quality is very far removed from his usual standard. It is a curious feature of these occasional lapses that the producer will stoutly maintain that they *are* good prints, and no amount of argument will persuade him to the contrary. Experience teaches that this state of affairs is due to a kind of "staleness," which results from keeping people of certain temperaments too long at one particular kind of work. The bromide printer knows that the print he is developing will undergo a change when it passes to the hypo, and will further alter in depth on drying, according to whether it is a glossy or a matt paper. He may have also in mind that the print is for subsequent toning and may be developing accordingly. After a time the experienced printer makes the necessary allowances for these changes of appearance automatically, and without conscious effort. The action is there, however, and if the worker is of a sensitive or quick-brained disposition, and allows other matters to crowd his mind while he prints, relying on his subconscious mind for accuracy in his work, he must come to a stage when the consequent fatigue of mind interferes with co-ordination between eye and brain. When that stage is reached, the man cannot tell whether the print is a good or a bad one, and a worker who is of the nature described should not confine himself to one branch of work. The stolid type of person, on the other hand, may be relied upon to produce the same standard of work at an even rate indefinitely, and usually is found actually to prefer long runs of the same style or size, or even of the same subject. Such workers as these, however, rarely rise to emergencies, such as the production of large quantities in an unprecedented time, or the extraction of quality from negatives that appear to contain none.

There is another disease that frequently affects the worker who is kept, for whatever reason, at one particular branch, and is not confined to printers. There is a famous firm who advertise that they employ only specialists in each branch, and while the growth of their business is evidence of the commercial soundness of keeping each person at the work that he appears best suited for, yet it would be interesting to know whether they do not encounter the complaint referred to, and if so, how they deal with it.

The mental trouble in question has no definite name that we know of, nor has it been recognised as a disease by mental experts, although it has spread alarmingly in this country among the large army of civil servants which the war and its results have produced in our midst. Its symptoms are exemplified daily in newspaper descriptions of extraordinarily obtuse acts of bureaucratic red-tape. In photographic workshops it is found in all branches. It may be the retoucher who cannot understand why his work does not print so nicely as it looks, and cannot adapt methods of finishing negatives to suit subsequent operations. Or it may be that the gelatine of a plate presents some idiosyncrasy that makes opaque difficult of application, and the latter may have "gone wrong." At last, repeated efforts have succeeded in blocking out the subject, but the printer complains that

the extreme thickness of colour prevents sharp contact, and fine detail is blurred in the print. The retoucher puts the blame on the man who developed the plate and omitted to wash out the hypo. The printer blames the retoucher. They all forget that the prints are useless and the job must be done again.

In such a difficulty as that described, how much easier it would be if the workers would hob-nob and for the nonce sink their individual "dignity," to see if there is not a way out. They might even go so far as to consult the head of their firm or department, as there is always the possibility that he may have encountered such a "snag" before. In any case, he is almost sure to detect the fault and to know how the trouble could have been prevented. In the case in point he would decide whether if bad washing were the original cause it would not save time in the long run to wash and dry the plate again. If the "developer" were above taking such a suggestion, even in the form of a request from the retoucher, he could not well refuse the chief. The latter might point out that a more rapid cure might have been effected by varnishing the negative, or by the application of ox-gall, a supply of which would be obtainable (as a special favour, of course) from the finishing artist or from the print-glazing department. If none of these suggestions proved effective, he might direct the printer to make the prints through the enlarging lantern, and obtain sharp detail by that method.

The point of the argument is that it would be very much better for assistants in every branch to be mutually helpful, and not, in a case where difficulty occurs, merely carry out their individual part of the work in a hide-bound, quasi-conscientious manner, knowing that the results will be unsatisfactory, but prepared with an excuse which will seem to throw the responsibility on someone else; ignoring the fact that it is the photographs, and not the excuses, on which in the last resort their bread-and-butter depends.

SOME COMMERCIAL APPLICATIONS OF GASLIGHT PAPER.

THERE are two characteristics of the slow contrasty varieties of gaslight paper which hitherto appear to have escaped general notice, but which happen to be a combination of virtues of which I have been able to make considerable use in directions other than the making of ordinary prints from negatives. The properties referred to are, first, that a well-developed black upon a gaslight paper is a deposit that is actually opaque or sufficiently so to serve as a mask in printing on bromide paper, whereas a black on bromide paper is a very poor thing by transmitted light; and, secondly, that such blacks do not irradiate on to the adjacent white portions to the very slightest degree.

It becomes an easy matter, therefore, to obtain a very satisfactory line negative by contact from a tracing or similar translucent original, of sufficient brilliance to give with ease a bromide print that will very often surpass the original in quality. Unless the original has lines of absolute opacity, printing the negative requires care in getting reasonably correct exposure, in order that the gaslight paper may be developed long enough to get density without getting image over the lines. It is surprising what a slight amount of tint on the lines is enough to degrade them in the final prints; but then, again, with under-exposure a good solid black is not obtainable. It is better to make sure when working from a weak original that the lines remain clear, and trust to using a contrasty bromide paper to obtain brilliant prints. It is also essential to use plenty of fresh strong developer, and to avoid a suspicion of yellow stain. I do not think it is necessary to dwell any further on the technical procedure, and I will therefore proceed to describe some examples of the ways in which these paper negatives have proved useful in my work.

On more than one occasion a letter or other document has been brought to me on which the holder has set an extraordinary value, and has desired the negative to be made so that he may regain possession of the original while he waited. It has not required much experience to be able to decide quickly whether the paper of the original is sufficiently even in texture and translucent to permit of the method being used. Obviously, only originals having matter on one side are suitable, but it is quite surprising how some apparently rough papers will allow of satisfactory reproduction. The one thing that will prevent success is patchiness of density, especially if the irregularity inclines to yellowness, that colour being non-actinic in the extreme to gaslight paper. With a half-watt lamp in the printing-box, or a number of tungsten lamps, the exposures will average about a minute, so that it becomes easy to make a trial strip and then a full-size negative in the printing room in considerably less time than a glass negative can be made in the copying camera, and the annoyance often expressed as the result of putting pins through the corners will be avoided.

A letter in ordinary purple typewriting is rarely suitable for reproduction by this method, but black will turn out well

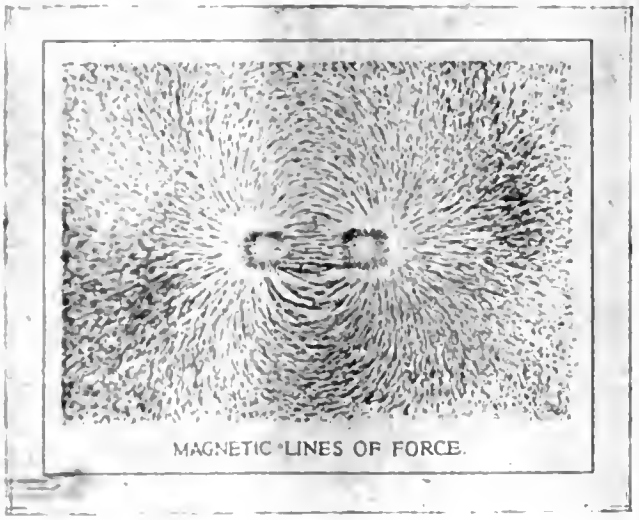

Fig. 1.

if the writing has been done with a fairly new ribbon and the paper is of good quality. Once a satisfactory negative has been obtained any number of bromide prints can be quickly and easily made from it. Using a light in the printing-box of a strength that normally would be employed for printing upon gaslight paper, the exposures from these paper negatives on bromide paper will be in the neighbourhood of five or six seconds.

Another occasion on which the method came in very handily was when I was asked to make a series of photographs of the "lines of force" produced by magnets of various kinds with

iron filings. The ordinary illustrations in books are from drawings, but it was desired to produce the "real thing." To do this it would have been necessary to arrange for vertical copying in the camera, but the use of gaslight paper produced a set of half a dozen different photographs in less than half an hour. They were made as follows:—The magnet (or magnets) was laid flat on the table or held between two blocks of wood, according to the result desired, and a waste negative rested upon it. A sheet of gaslight paper would then be laid upon the glass, and a sifting of iron filings be made over it as evenly as possible. On then giving the glass a slight tap the filings would spring into the lines desired, and a light was turned on to the paper. The characteristic properties of gaslight paper referred to at the beginning of this article resulted in the negative recording every detail of the filings to the very finest particles, and a bromide print from it needed holding only a very short distance away to present a perfect illusion of actual filings. One example is shown as an illustration, and the border line and title are introduced to show another application of the gaslight negative process.

I was asked at one time to make a considerable number of prints from whole-plate negatives masked out on to larger paper, and at the same time to introduce a simple border and title. About a dozen or two prints were required from each of a large number of negatives, and each border was to be of proportions to suit each individual subject, as was also the mask opening, so that each negative had to be treated individually. After some experimenting, the method was worked down to absolute simplicity; that is to say, that it was rendered so for any competent bromide printer, so long as each point of the procedure was carefully done. If, however, a less experienced person was given part of the work to do the results were unsatisfactory. It was found necessary to carry out the preliminary work by skilled and conscientious labour, although each operation is simple in the extreme, in order, first, that the paper negative should give a clean black line without the ground printing through and still permit of reasonable latitude in exposures; and, second, so that the registration of the title negative with the mask for the tone negative should be accurate, for nothing looks worse than a border which is neither square nor equi-distant with the edges of the subject. The pains taken in working out the method and in resolving it into a series of operations which were simple if carefully done, resulted in an enormous saving of

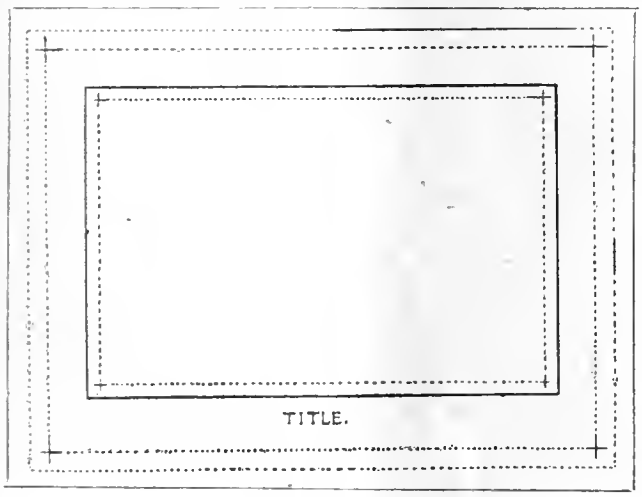

Fig. 2.

time and absence of trouble and waste in the final results, and permitted the titled prints to be produced with a very high-class appearance on "mass-production" lines.

The actual writing of the titles was done by a draughtsman, of course, who followed my instructions, as follows: Proof prints, trimmed to the dimensions in each case that should show on the finished result, were handed to him in batches, each one bearing on its back the wording of the title as well as the negative number. It was found that although various tracing papers gave excellent results, tracing-cloth resulted in cleaner lines, and the work was set out on sheets of this cut a little larger than the prints were to be. The negatives (mostly whole- and half-plate) were to be masked on to 10×8 paper, and the tracing cloth was cut to about 12×10. Figure 2 shows how the work was set out

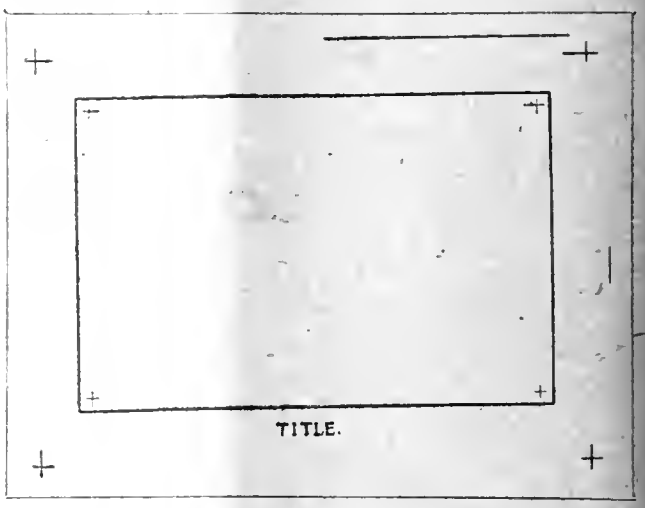

Fig. 3.

on each sheet, the dotted lines representing pencil, which was, of course, used first, and the essential lines inked in afterwards, when the remaining pencil lines were removed with a wad of cotton-wool and benzine. This was found to be another point where the cloth was better than most papers. The work was done with drawing ink, and when dry the tracing was placed in a retouching-desk with a strong light behind and weak places touched up with opaque. The outside line was drawn first, exactly 10×8, and inside that a line representing the size of the final print after trimming. The print was laid in correct position within this line, and the line drawn which obviously was to be the mask opening. Around this, at a suitable distance, was drawn the border line, and then the title was inserted. The pencil work finished, the tracing was *turned over*, and the negative number written on it *outside the* 10×8 *line*.

It will be understood that each batch was first done right through in pencil, then the ink work, after which the cleaning off, when the tracing appeared as in fig. 3, and finally the touching up with paint, and the other processes of negative-making, etc., were similarly done in batches on the "one operation-at-a-time" principle. There are several points in connection with the inking in that require mention, and the diagrams (which, in fact, are actual prints and negatives made in the manner described) will help to explain them. On the outside 10×8 line two ink lines are made, in the positions shown, a long one at the top right-hand and a quite short one in the right-hand centre. These are the registration lines. The next line has the corners inked in as shown, and these will show on the finished prints as "trimming guides" (see also fig. 1), which, if just cut off, will ensure that the print will be trimmed with equal and square margins, even if done by the most inexperienced. The mask also has its corners crossed, and all these lines should be made the very finest that a drawing pen will give (they are drawn coarsely here to ensure reproduction), but that end is not to be achieved by thinning the ink, or a translucent line will result, which is useless. If difficulty is experienced, a little burnt sienna water-colour, mixed in without any added water, will assist in making the line non-actinic. The border line itself, as well as the title, may be drawn any thickness desired, but for the rest the finer the better. The pencilled negative number is drawn in with less meticulous care than the other work, but it is essential that it should be of a bold character, and reasonably opaque also. The object of this is that the final

negative, which is a perfect black all over, will bear on it the corresponding negative number to which that particular title and border belong (see fig. 4). These negatives are therefore easily stored in files in numerical order, and can be got out just as easily as the subject negative when reprints are required. By reversing the number on the tracing, as described, it will read correctly on the negative.

Supposing, then, a batch of title-tracings is finished and cleaned off, it may be supposed that the next process is to print the negatives on gaslight paper as described before.

Fig. 4.

It isn't. The first thing the printer must do is to place each tracing on his printing-box and examine it carefully for weak places as regards density of ink and either correct these himself (soft pencil often is sufficient added density if done on the back of the tracing) or return them to the draughtsman. The most careful of the latter has sufficient of the artistic temperament in him to render him unreliable on this point unless kept up to scratch by more or less peaceful persuasion. Besides this one has the feeling when handing over a batch of fifty or so prints to have these tracings made that one would have less hesitation in asking a fellow-mortal to pick a quantity of oakum, so that one must expect human nature to show itself towards the end of a batch. However, having got our tracings done the negatives are made on gaslight paper of a size somewhat larger than the final prints, in the big order described 12 × 10 was used.

A trial or two will find an exposure that will permit the paper to be developed for a full minute, to obtain density, without clogging the lines. The old hand at gaslight will know, though the man who is used only to bromide paper will not, that the developer should in any case be not lower in temperature than 60 deg. F. It should be fresh and strong, and it will be found that these all-blacks take out the strength of the developer rapidly, so that it should not be stinted. By making sure of dense blacks and clear lines, which can be judged after very little practice as well on the surface as by transmitted light, not only will every negative require the same exposure in printing, but there will always be ample latitude, so that it will always be a matter of certainty that a black line will be on the final print without any fear of the ground showing, and whatever sort of development has to be given to suit the tone negative. Printing is done to suit the latter entirely, and the line stuff always comes up "merry and bright."

A number of tracings then, have had paper negatives made from them, the latter being well fixed, washed and dried in the usual way as though they were prints. They are preferably well "stroked," and then placed face to face under pressure, so as to get them nice and flat. The next thing is to make the masks, which is the part of the business that calls for most accuracy and conscientiousness. An equal number of sheets of paper, black or ruby, are required, which may be advantageously a little larger one way than the paper negative. The object of this extra inch or so is that the spare edge of the mask may be afterwards gummed to the negative so as to form a hinge, and allow of the two being kept together both in printing and in store, and thus avoid confusion and worry. The first thing to do is to place the masking paper on a sheet of cardboard, and to lay the paper negative face up upon it. A suitable masking paper, by the way, can be got in ruby from Messrs. Butcher and in black from Messrs. Kettle (fancy box manufacturers), of New Oxford Street, W.C. It is absolutely essential that during the next operation the two papers be not shifted in relation to one another, and if any fear be felt on that score it is advisable to fasten them together with a spot of adhesive in the centre, and in separating them afterwards it does not matter if a bit of the masking paper sticks to the negative.

All that is done while the papers are together is to pierce them in the following places with a fine, sharp needle:—Three pricks along the top registration line, well apart, but taking care to keep them in alignment: that is to say, if one does not quite hit the middle of the line the first time to keep the other holes on the same side of the line; then two near together on the short registration line, and one on each corner of the central mask line, that is to say, the absolute centre of each of the four little crosses. All that remains to be done after separating the two sheets again and gumming the two edges, so that they are now side by side instead of one on the other, is to cut out the mask by means of the four pin-pricks as guides, and to spot the negative by covering the small crosses now with bits of slide binder and with opaque for any dust spots, etc., and then to stick on a strip of stout light-coloured paper against the pin-pricks on the registration lines, on both negative and mask (figs. 4 and 5). It will be recognised that any inaccuracy in making these pricks or in sticking on the strips will be shown on the finished pictures by want of centralisation of the picture within the border line, but there is no real difficulty, only care is needed. If it is decided to dry-mount the registration-strips on, it is advisable to press both the masking paper and the negative in the hot-press before pricking the two points, as the amount of shrinkage in each may not coincide.

The procedure of printing from these borders is as follows: The standard exposure for the paper negative is first found,

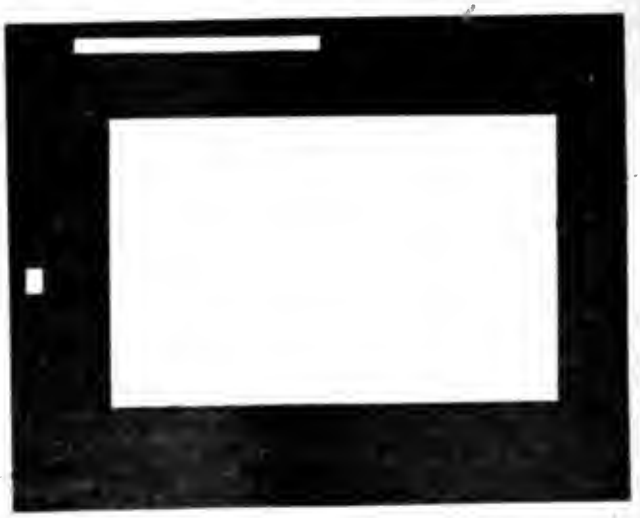

Fig. 5.

using preferably a powerful light for speed, and remembering to give plenty rather than to skimp the exposure. The tone negative is then laid in a cardboard carrier, so that it will not slip about on the printing-box, and the mask adjusted over it. Having determined the correct exposure, preferably *not* by guess, the requisite number of sheets are exposed, feeding each one against the registration strips. It will be seen that having one long one and the other being only a narrow stop piece, paper which happens to be cut not perfectly square will be just as correctly and easily fed. Having

exposed the required number of sheets on the masked negative, this is removed, and the sheets are fed and exposed to the line negative.

Probably many will consider it superfluous if I add that it is advisable to mark each sheet, so that there is no chance of reversing the prints between the two printings, but experience teaches that it is very necessary. A very good way is to cut off a very small corner of the whole pile of paper before printing each subject, and always keeping the cut corner at the top right hand in working. In practice also it will be found helpful to make a full-size trial in the following way of each subject. First of all, a full sheet is exposed on the line paper negative, and is laid on one side while the mask is arranged over the tone subject negative, which is then shaded if required, and the best exposure found by trial strips. This done, the previously printed sheet is exposed for the centre and is developed. This will not only act as a check on the accuracy of the masking work, but is rather desirable when first taking up this style of thing to give confidence. The description of the process, owing to the detail with which each operation has been described, may seem rather complicated and difficult, but, except for the fact that it is rarely worth while doing for a very small number and shows its advantages best when large quantities are required, it will yet be found very practical. For cases where one usually has letterpress printing done on mounts, with the alternatives of having more printed than one needs or being unable to supply reprints, this method will be found to have great advantages, because one can produce the actual number ordered without waste, and still be in a position to reprint at any time.

The same method of working is useful again when intricate machines are photographed and a display is required of lettering, describing the various parts with long arrows to each. Instead of setting out the wording on a large sheet of paper, in the centre of which is a print mounted, and subsequently copying the whole, one can produce a blocked out print with the matter inserted by double-printing without any loss of gradation in either the lettering or the subject, and can just as easily reprint at any time.

One more example of the utility of the gaslight-paper negative which has on several occasions saved time and money will conclude this article. A number of line blocks were required of diagrams of which the majority of the details were identical, but others, again, were to be different in each, and in some of them the wording was to be changed in part, and, again, was to be in one case in a totally different language. To draw the required number of copies of the complicated diagrams would have entailed many days' draughtsmanship. On being consulted I had the first one executed completely on a sheet of tracing cloth, and made a gaslight negative from it, the size being about 12×10. Then, with a bottle of mahogany varnish stain from the oilshop, the details that were required to be altered on the second block were painted over on the film side. As soon as dry a print was made on bromide paper on which the now missing details could be drawn in. The varnish stain dries very rapidly, so that it did not take long to make the whole series of prints, and in cases where a part that had been deleted was required in a subsequent copy the varnish came off with methylated spirit. The resulting bromide prints make admirable originals for the block-maker, and are easy to draw upon. Except in the case of glossy bromides which may not have been very well washed and have been dried off with spirit, there may be a little reluctance to take the drawing ink, and any trouble taken to overcome this does not cause less delay than blotting off the print as it comes from the washing-water and drying it as near a source of heat as may be safe. Matt prints, on the other hand, are better for taking colour if dried off, but will then take on a more obstinate curl, with the liability to crack on any attempt being made to straighten it out.

Many more instances could be given, but I think sufficient has been said to enable anyone to decide whether the process will prove useful to him, and, if so, how to carry it out to the best advantage.

D. CHARLES.

DEVELOPING AND PRINTING OF CINEMATOGRAPH FILMS.

To the photographer who has not had the good fortune to witness this part of the preparation of a film before it is shown on the screen, it has always seemed a huge and almost impossible proposition.

I should like to show my professional brethren the similarity to the preparing of the finished glass negative and prints to which they have so long been accustomed.

The length of film to be developed is usually anything up to 200 ft. and $1\frac{3}{8}$ in. wide. This, after having passed through the gate of the camera is now, we will assume, in the bottom box, or as is more generally known in the trade, the "take up" box, this being the one into which the film is wound after exposure.

The film is then conveyed to the dark room and there developed in either of the two ways which are in general use to-day. One is by means of what is known as the "pin frame" (fig. 1).

As one can see by fig. 1, this frame, diagonally and across the centre, has pins rivetted through the tubes. The size of a frame to take 100 ft. is 20 in. square; or 28 in. for taking 200 ft. of film.

To wind on to a pin frame of this description, one takes the roll of film and folding back a portion, viz., 1 in., a pin is inserted through both, thereby forming a loop which is put over one of the four centre pins, taking great care that the film is emulsion side outwards. The rest is then wound spirally and outwards, not missing any of the pins nor winding over the same pin twice and keeping the film moderately tight.

Having reached the other end of our film, we now make another loop as at first, and placing this over also, it is now ready for the developing dish or flat trough whichever

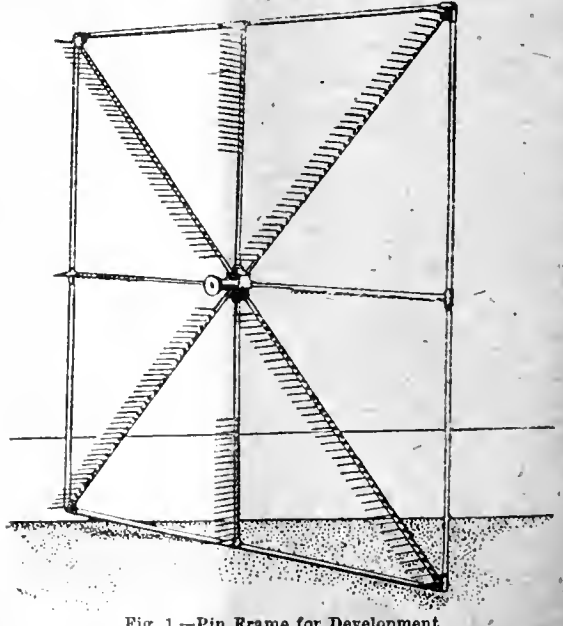

Fig. 1.—Pin Frame for Development.

is most suitable. The size of a pin frame dish holding 200 ft. is approximately 31 in. square and 3 in. deep. The

second method is by means of a flat wooden frame (fig. 2) over which the film is wound over and over up one side and down the other slightly on the slant. Pins placed top and bottom serve to keep the film from over-lapping.

Again the film is looped and pinned over the top edge, and assuming the wooden frame is on its winding stand, as the frame is rotated one can guide the roll into the grooves made by the staples fixed on the top and bottom. The size of a flat wooden frame to hold 100 ft. is 32½ in. square and 1½ in. wide.

Using a flat frame is simple and quick, but I would here utter a note of warning not to commence with a new film but to gain experience first with some old stock film which, if damaged, will not matter.

We are now ready for the developing and we can either use the flat trough or upright tank. For pin frames,

Fig. 2.—Frame for Winding Film for Development.

flat troughs are nearly always used. For flat frames, we can use both.

As regards developer, any good metol-hydroquinone formula suitable for Kodak film will do. An all-round developer for topicals, both negative and positive, is:—

Metol	3	ozs.
Hydroquinone	1	lb.
Potass metabisulphite	½	oz.
Citric acid	½	ozs.
Potass bromide	½	oz.
Soda sulphite, cryst	1	lbs.
Soda carbonate cryst	2	lbs.
Water	1,300	ozs.
	(8 gallons Imp. approx.)	

Sixty pints will be sufficient for a 200-ft. frame; for 100 ft. allow 25 pints. Be sure to take the temperature accurately

Fig. 3.—Wooden Developing Frame on its Winding Stand.

before placing the frame in the developer, the correct and best being 70 deg. F. Normally-exposed film will then develop fully in 5 to 7 mins. As to the raising of the temperature in winter, my reader will no doubt be in a position to supply the necessary appliances, but a good method is by means of a non-luminous electric radiator with variable resistance.

Two methods can be used for the development of film. It can be plunged into the trough and judged by inspection,

Fig. 4.—Frame in Developing Dish.

or by cutting off a portion of, say, six inches previous to winding on the frame and developing separately. By the latter method we can judge the best time to allow the remainder to secure the best result, especially if we have cut that six inches again into four and allowed each piece to remain in the developer for a longer time.

After the film has been developed it will be subjected to the same treatment as an ordinary plate—that is well washed

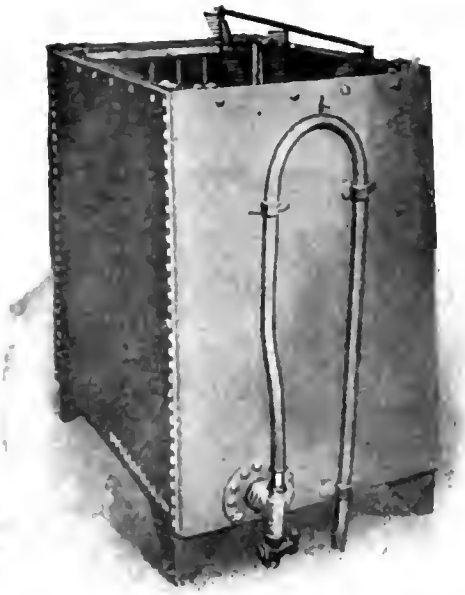

Fig. 5. Upright Developing Tank for Several Wooden Frames.

and transferred to the acid hypo bath. The Kodak formula for this latter is:

Hypo	20	lbs.
Hot water	57	pts.

When dissolved add the following solution:—

Crystallised soda sulphite	8	ozs.
Powdered alum	8	ozs.
Acetic acid	8	ozs.
Water	2½	pts.

B

It remains in this bath with occasional movement to prevent oxidation for 15 to 20 minutes, when it should be completely fixed, provided the bath is at full strength.

The film is then transferred to the washing tank and washed in running water for one hour. From this, the film can be then transferred back to the holder of the flat wooden frame and used for drying by keeping it spinning by hand, taking care that no damage results from the water thrown off; and care must be exercised to avoid dust.

This would not be much use commercially, so a motor-driven circular drum upon which the film is wound, emulsion side outwards, is arranged. It is a light cylindrical wooden cage revolving on a central shafting. To place the film upon it, one end is detached from the frame and securely pinned to one of the laths; again I must mention that caution—*emulsion side outwards*. Then, pushing the drum slowly away from you, guide the film which unwinds from the frame so that it spaces itself properly upon the drum slats without either undue tightness or slackness, and fasten the other end as at the beginning.

A drying drum capable of holding 500 ft., turned by an electric motor at 150 r.p.m., will dry in 25 minutes in a room of 80 degrees. After the film is dry it is then rewound by a re-winder and is ready for printing.

Printing.

The beginner in cinematography need not fear this part of the process any more than the taking and preparing of the negative.

Printing the cinematograph negative film is much the same as taking a print from an ordinary photographic negative, in that the emulsions of both must be in contact; but what we require is a series of continuous set of prints or positive films each showing or reproducing that difference of

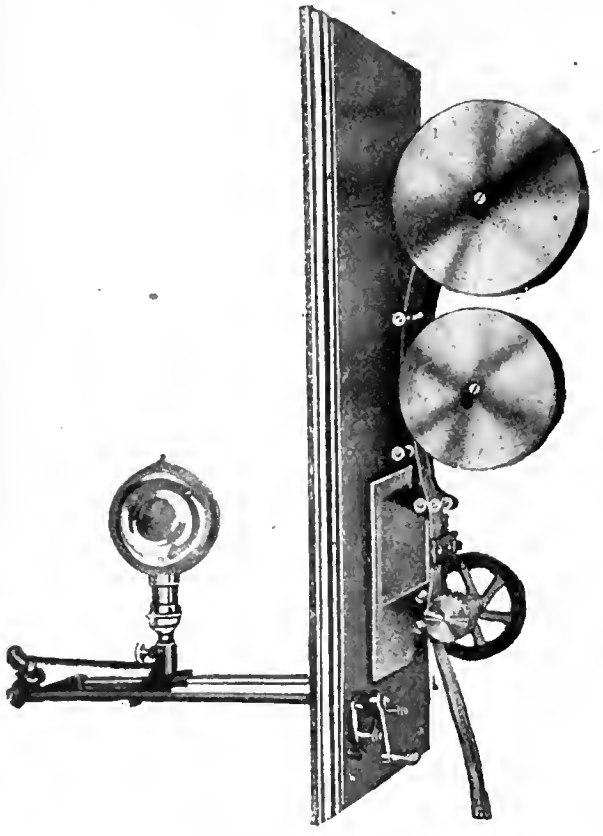

Fig. 6.—Continuous Printer.

action which we secured with the camera. There are two methods in use for this, one being by means of a continuous and the other by a step-by-step printer.

The continuous printer carries (fig. 6) a double arm for the negative and positive film, both of which pass in front of the exposure aperture to which is fastened a pressure gate keeping the two films in contact, and from there over a continuous moving sprocket and into a suitable receptacle such as a film bin. This machine is usually screwed to a partition wall or box in front of an aperture behind which a light

Fig. 7.—Step-by-Step Printer.

is placed. The light is adjustable as regards its distance from the film.

Need it be mentioned that the only bright light that should reach the film must be through the aperture gate, with the exception of the orange light used in front to work with. This is the most suitable form and preferable to ruby.

Cheap continuous printers are usually operated by hand, but for serious work a 1-16th h.p motor can be attached. Exposure can then be altered in three ways, viz., by the speed of motor, altering the candle power of lamp and shifting the distance of light-source from the film or gate aperture. Commercially the practice usually adopted is to keep the running rate and light the same, and adjust the exposure by shifting the light backwards and forwards only.

The step-by-step machine (fig. 7) is very similar in working to the cinematograph camera. The rolls of negative and positive are placed upon their respective rollers on the top. Then, threading them over the top sprocket with the perforations engaging the teeth of the same, we pass both with their emulsion sides in contact down through the gate, leaving a loop above and below the bottom sprocket and finally thread on to their respective rollers on the bottom for rewinding.

The printer is divided into two compartments. The lower contains the motor and a system of pulleys by which the different speeds may be obtained and also further controlled by another regulating switch. The upper compartment contains the lamp and is lined with asbestos. The latter is fitted on a slide controlled by a lever on a quadrant fixed in the front of the machine, and allows the lamp to be moved any distance from 2 in. to 10 in. from the printing window. This is further controlled by a regulating switch giving six variations of the light from 16 c.p. to 50 c.p. When the door is closed the compartment is light-tight and

perfectly ventilated. The gate aperture is of full size, viz., 1 in. and ¾ in., and the actual printing of each picture takes place while the film is stationary in the gate, as a rotating shutter placed between the lamp and film covers the aperture through which the light reaches the films at the time they are drawn downwards by the claw movement which is operating similar to that in the camera and uncovers again immediately the new section is in position.

This system is considered to be quicker, as by the combination of cone pulleys and regulating resistance, the speed of the film at the printing aperture may be varied from 80 to 500 pictures per minute. The machine may be run with perfect safety at this speed, at which the output of one machine is over 1,750 ft. per hour.

There is also a means for altering the masking of the picture, a necessity where one is printing different films that have been taken by several models of cameras. Having secured the print, the development of it is now the same as for the original negative.

P. KING.

USING BIRTH RECORDS TO HELP BUSINESS.

[In the following note, published in a recent issue of "American Photography" an American professional worker gives some hints on what we believe to be a novel plan of increasing business. All the ideas formulated in the note may not meet with the entire approval of workers on this side of the "herring pond," but there are some that may, nevertheless, the article is most interesting, showing as it does the way "boosting" is carried out by our brethren in the United States.—EDS. "B.J."]

EVERYBODY, very nearly, is interested in babies and in baby pictures, and there's nothing like a youngster or the photograph of one to arouse women and men, too, for that matter. Babies are the one big, universal, continuous interest of people in cities and in the country everywhere.

Because of this deep and abiding interest in the infants it generally needs merely a suggestion on the part of some person to induce the fond parents to take their offspring to a studio to have his picture taken. But, lacking this suggestion, the propitious time is passed by and some photographer loses trade that he should have, and also loses the opportunity of lining up the parents and relatives of the child for any future photographic business they may be in the market for. Now why shouldn't the photographer himself suggest to the parents that they secure photographs of their children? And why can't the photographer make such suggestions in a way that will inevitably secure the trade of a very large percentage of the people to whom the suggestions are made?

This sounds reasonable enough, but how is the photographer to go about making such suggestions? And, more important still, how can he so limit the suggestions made that he will not waste his time talking to a lot of folks who are not interested, because they have no children? If he uses newspaper advertising as the medium for suggesting to parents that they let him take photographs of their children, then the photographer will be spending money to reach a lot of folks who aren't in the market. Is there any way by which the photographer's efforts can be concentrated so that he will get at only interested people? There certainly is, and it is the purpose of this article to call attention to a method by which this can be done.

In every city and in every county vital statistics are kept by the proper city and county officers. Included in these statistics are complete birth records for the city and county. Generally it is the city or county health officer who keeps these statistics. Now suppose that the photographer goes to the proper office and looks over the birth records for one, two, three and four years previous. These records, of course, are public property and may be referred to by any person who desires to do so. Suppose that the photographer secures lists, from day to day, of the first, second, third and fourth birthdays of local children. Suppose that he has one of his employees find out by telephoning neighbours of the parents whether or not the children are still living. And then suppose that the photographer sends out to the parents some two or three weeks ahead of each child's birthday a circular letter, nicely spaced out and paragraphed, and reading something like this:—

"Congratulations on your son's second birthday! It will be an auspicious occasion when your son reaches the second milestone in his career on next Tuesday. And from then on, of course, it will seem as though his birthdays come faster and faster. Soon, all too soon, he will be in long trousers—will reach his majority. When your son is twenty-one, will you be able to remember the way he looks now? Children so quickly grow up! Mother's baby so soon becomes a full-grown man! Why not catch and retain for ever his present cuteness, winsomeness and sweetness? Why not celebrate your son's second birthday by having his picture taken at this studio now? Certainly there is no time like the present for taking the picture of a baby. Do it now! We are specialising in photographs of babies, and our friends tell us that we are securing splendid results. We're sure you will like the pictures we take of your son. Step round to our studio any time and look over our interesting collection of baby pictures, among whom you'll probably find the offspring of some of your friends or relatives. Or better, call us up and make an appointment. There isn't the slightest doubt in the world that if you have your baby's picture taken now you will be immensely glad of it in the years to come.—J. L. Smith, Blank Studio, etc."

Suppose that the photographer varies the letter appropriately if the child happens to be a girl, and suppose that every day he posts from twenty to fifty letters of this character. Would not the use of such an interesting, novel and attention riveting direct mail advertising stunt as this be calculated to make all parents sit up and take notice? And wouldn't such a stunt be certain to bring in a lot of additional business to the enterprising photographer who is engineering the proposition? As has been stated before, folks are always interested in babies, and, naturally, they are much more interested in their own children than in the children of other people. Consequently, when a letter of such a character as the foregoing is received by any parents, the natural thing for them to do would be to preserve the letter and to talk the matter over seriously.

One can imagine the sort of conversation that might occur between father and mother:—Father (with a pleased smile): "Well, our son must be getting to be pretty well known when a stranger knows all about the time when his birthday occurs." Mother: "I'm curious to learn how they found out about his birthday. Do you suppose some friend told them?" Father: "I haven't the slightest idea. But I tell you what I'll do—I'll drop in there and ask them." Mother (smiling): I know just exactly what you mean by that—you mean you'll go down there and talk about baby to the photographer, and end up by making an appointment to have baby's picture taken!" Father (unabashed): "Of course, that's what I intend to do! We surely ought to have a picture taken of him on his birthday." Mother: "But you know that when we talked about having the photograph taken we spoke of going to Brown,

who took our wedding picture.' Father: "We should fret about Brown. I like this man Smith's enterprise. He deserves something for reminding us that we ought to have the baby's picture taken. So we'll go there."

Wouldn't this be just about the sort of conversation occurring in the families of people receiving the letters? And wouldn't it be certain that many of the folks receiving the letters would make it a point to act on the suggestion conveyed to them and have their infants' pictures taken at once?

It wouldn't be a hard proposition, nor an expensive matter to put a promotion plan of this sort into effect. It would take only a small space of time each day to look up the right birth records for that day and to ascertain the present condition of the family by telephoning. As the letters would all be of the same form the actual work of mailing out the letters would be very small indeed. And whatever amount of time or work was involved in putting the scheme into work, wouldn't it all be very much worth while, in view of the increased business, the increased prestige and the great amount of word-of-mouth advertising which the photographer would secure through the operation of the plan? Try it and see.

FRANK H. WILLIAMS.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[The fifth annual volume of reports upon progress in the various branches of chemical manufacture, issued by the Society of Chemical Industry, includes, as did the preceding issues, a report on photographic materials and processes. This is again by Mr. R. E. Crowther, A.I.C., who (writing early in the present year) reviews the literature, published during the year 1920, representing original contributions to the technical improvement of processes of making negatives and positive prints, orthochromatics and colour photography, cinematography and photo-mechanical processes, and also the methods of research and measurement which are generally described as "sensitometry." Inasmuch as these reports are, so to speak, a series of annual stocktakings of what has been done during the twelve months preceding the issue of the volume, we have naturally wished to give them a place in our pages, since no other publication of the year so well reviews what has been done in reference to the current state of knowledge. As regards the references to original sources of publication, it should be explained that the contraction "J" denotes the fortnightly "Journal" of the Society of Chemical Industry in which are published abstracts of the chief papers relating to photography from the chemical standpoint.—EDS. "B.J."]

(*Continued from page* 462.)

Panchromatic and Colour Photography.

THE theoretical considerations which affect the orthochromatism of the results obtained on "self-screened" orthochromatic plates have been enumerated by Lüppo-Cramer.[28] It is pointed out that by suitable variation of the exposure and development of such plates, it is possible completely to reverse the photographic effects of blues and yellows. Inasmuch as "depth" development give the truest orthochromatic renderings on these plates, efficient anti-halation backing is a *sine quâ non* of correct technique. A fair amount of material has been published on the application of the isocyanines and allied dysetuffs as colour-sensitisers, and it is interesting to note that the property of conferring extra sensitiveness on an emulsion has been cited as evidence of chemical constitution.[29] W. J. Pope and W. H. Mills have given an account of their researches on the isocyanines,[30] which result from the alkali hydroxide condensation of quinoline alkiodides with quinaldine alkiodides, and on the carbocyanines,[31] prepared by the condensation of two molecules of a quinaldine alkiodide with one molecule of formaldehyde under the influence of alkalis. The original papers should be consulted for details as to the methods of preparation and examination of the dyes investigated. As far as the sensitising properties of the isocyanines are concerned, the following conclusions may be recorded:—1.1′-dimethylisocyanine iodide possesses powerful sensitising properties, and the maxima for the extra-sensitiveness conferred lie at 5850 and 5350; the positions of these maxima are only slightly affected by the introduction of other methyl groups. The whole spectrograph curve is rendered more uniform by the introduction of a methyl group in the 6-position and the maxima are depressed by introducing a third methyl group in the 6′-position or three methyl groups in the 2′.6.6′-positions. The total induced sensitiveness diminishes steadily as the molecular weight of the dye increases. The substitution of methyl by ethyl leads to a notable diminution in the sensitiveness for red and green light. The diethyl compound (1.1′) is affected similarly to the 1.1′-dimethyl derivative by the introduction of a methyl group into the 6-position or into the 2′-position, indicating a definite relation between the sensitising action and the chemical constitution. The introduction of a cyano or a phenyl radicle into the 2′-position practically annuls the strong sensitising action of the 1.1′-dialkylisocyanine iodide, a fact which, taken in conjunction with the modern views on the interaction of light waves with compounds consisting of two basis groups—one saturated and the other unsaturated—connected by a chain of conjugated ethylenic linkages, leads to the conclusion that all the 2′, 3′, and 4′-substituted isocyanines will prove to be feeble sensitisers.

In the carbocyanine series, the most important member of which is Sensitol Red (Pinacyanol), the derivatives generally exhibit a decrease in sensitising action as the size of the substituent group increases. It is suggested that the type distinction between the isocyanines and the carbocyanines lies in the coupling of two quinoline residues by the link :CH— in the former case, and by the conjugate chain :CH.CH:CH— in the latter. The multiplication of the number of units of the constitution :CH—, which occurs in the carbocyanine is accompanied by an extension of the extra-sensitisation far into the red region of the spectrum. Although for obvious reasons no variations in the method of applying the dyes to the plate were tried, it would no doubt greatly increase our knowledge of sensitisation mechanism if the opportunity afforded by the possession of what must constitute a unique range of homologous substances, were taken, and an investigation in such media as collodion, etc., carried out.

H. Barbier[32] has described the methods of preparation of dimethyl- and diethyl-amino derivatives of the condensation products of quinolines, quinaldines, and lepidines, all of which are stated to be of interest as photographic colour-sensitisers, and L. E. Wise and E. Q. Adams have been granted patents covering Pinaverdol[33] and the 1.1′.2′.6.6′-pentamethyl derivative of isocyanine.[34] The latter compound, however, does not appear to be of outstanding value (*vide* [35]).

The addition of Auramine to the dyes which are generally used for colour-sensitising has been found by F. F. Renwick and O. Bloch[35] to yield improved results by enhancing the

sensitiveness in regions not sensitised by the Auramine alone, and by the suppression of the well-known tendency of the isocyanines to produce fog. The action of the Auramine may conceivably be chemically related to that of ammonia, which latter has been studied by S. M. Burka,[35] whose work has demonstrated that the so-called "hypersensitising" does not of necessity lead to the production of fog or to pronounced loss of keeping qualities.

The keeping qualities of even pre-war panchromatic plates have been found by L. T. Woods[36] to be of a very high order, and with the purer dyes which are now available, all modern panchromatic plates should show but very slight deterioration after prolonged storage.

Two hitherto unknown methods of imparting colour-sensitiveness to gelatino-bromide emulsions have been referred to during the past year. J. G. Capstaff and E. R. Bullock[37] have found that treatment of a plate with dilute sodium bisulphite or bicarbonate solution, followed by washing in distilled water, confers marked sensitiveness in regions of the spectrum to which the original emulsion was insensitive, and F. F. Renwick[38] has noticed a similar action of dilute solutions of potassium iodide and cyanide. He suggests that the fogging effect of the former salt, noticed by Sheppard and Meyer, and attributed by them to nuclear infection, was the result of such sensitisation and subsequent exposure to the red light of the dark-room. No theoretical explanation of this sensitisation by inorganic salts has been so far offered by Capstaff and Bullock; Renwick[38] on the other hand, suggests that the treatment with the sensitiser causes an alteration in the dispersive state of the solid solution of colloidal silver which he has previously referred to as the sensitive entity in ripened emulsions (*vide* [1]). It is perhaps noteworthy in this connection that whereas a dilute solution of potassium iodide (1:5000-1:50000) induces red-sensitiveness in an unexposed emulsion, stronger solutions (1:100) induce a sensitiveness in the latent image which is confined to the blue end of the spectrum.

Before passing to the year's work in colour photography it may be noted that A. Miethe and E. Stenger[39] have examined spectroscopically several dyes which can be used for the preparation of filters transparent to ultraviolet light, and K. S. Gibson, E. P. T. Tyndall, and H. J. McNicholas[40] have published curves showing the properties of the filters which have been found most useful in the detection of camouflage.

In colour photography the outstanding novelties are perhaps the processes of Katsujiro Kamei and W. V. D. Kelley, both of which are particularly applicable to cinematography. In the former process[41] a suitable arrangement of colour filters and prisms allows of each projected picture being a composite image of two simultaneously recorded colour images and successive pictures exhibit different regions of the spectrum. The sequence of colours is so chosen that not only is the combined effect truer to nature than is generally the case, but also eye irritation is largely eliminated. No attempt is made apparently to adjust the contrast of the colour-sensation negatives to compensate for the variation due to the wave-length of the light recorded on the negative. The variation of gradation due to wave-length differences has been investigated by A. Hnatek,[42] who finds that the curves obtained by plotting gradation against wave-length show in all cases an S-formation, rising from short wave-length up to a maximum for ordinary plates at about 4,500$\mu\mu$, falling to a minimum, and then rising again at about 4,900$\mu\mu$. Chromatic plates show some variation both as to position and height of the maximum. These results explain many of the seemingly contradictory statements which have been published on this subject. W. V. D. Kelley[43] has been granted a patent for a process of colour cinematography in which a double coated positive film is "ruled" by exposure under a symmetrical grating, so that the lines on one side correspond with the spaces on the other. By printing on this film from colour-sensation negatives and then toning the images (and rulings) to the complementary colours, a natural coloured additive picture is obtained when the film is viewed by transmission (projection). Provided that in successive pictures the screen pattern does not always occupy identical areas, the process should give excellent results.

The substitution of a blue filter for the green one during a portion of the exposure of the green sensation negative in two-colour cinematography—the more distant the object being photographed the greater is the proportion of the exposure through such blue filter—has been patented by L. F. Douglass[44]; whilst W. V. D. Kelley[45] has patented the expedient of giving an unscreened partial exposure when taking colour-sensation cinematograph negatives. Both these modifications, to carry out which will entail, unfortunately, complications in the apparatus, should lead to more harmonious renderings of the projected images. In additive colour work not primarily intended for cinematography, phenol-formaldehyde condensation products have been recommended as components of the "screen" by M. Wieland[46]; the ability to withstand somewhat rough usage, coupled with their insolubility, renders such products eminently suitable for the purpose. The use of fine transparent grains of magnesium carbonate as proposed by T. Silbermann,[47] does not appear so promising, as very efficient waterproofing protection would have to be applied over the grains in order to prevent their being attacked by the solutions which are used for reversal of the image in non-symmetrical screen-plate colour photography.

It is pointed out by P. R. Kögel[48] that many of the benzopyrilium (anthocyan) compounds occurring in flowers are sufficiently light sensitive for use in the bleach-out process. *o*-Anethol was found to sensitise several otherwise unsuitable colours of this class, and by reason of its sensitisation to light by thiosinamine it is concluded that Rhodamine S is constitutionally related to cyanidine chloride—a further instance of the application of photo-sensitiveness in the study of chemical constitution. The same worker[49] has detailed the conditions which it is necessary to observe in order to obtain prints in colour by the use of coloured enolic compounds. As the mordant dye process of producing coloured images is likely to become of increasing importance in natural colour positive work, it is of interest to note that F. E. Ives[50] has improved his method of bleach-mordanting the silver image so that a translucent or transparent result may be obtained at will.

Positive Processes and After-Treatments.

A method of measuring the gloss of photographic printing papers which depends upon the polarisation of reflected light has been described by K. Kieser,[51] and F. Formstecher[52] has modified the well-known crossed-wedge process in such a way as to make it of relatively easy application to the determination of the characteristic curve of printing-out papers. The last-named worker has also published[53] the results of his researches on the colour of the images given by printing-out papers. He confirms Chapman-Jones' contention that the colour is a function of the size of the precipitated silver particles, and finds that emulsions having a low citric acid content give blue images, whilst redder and softer results are obtained as the proportion of this acid increases. G. Staess[54] proposes to increase the steepness of gradation of the print when using printing-out paper by interposing between the negative and the paper a thin film of gelatino or collodion

stained with ferric thiocyanate, the colour of which is bleached inversely in proportion to the opacities of the negative being printed. R. Namias[58] recommends the addition of small amounts of alkali to the sensitising bath used in the carbon process with the object of obtaining papers which exhibit enhanced keeping qualities. Before printing, the alkali is neutralised by fuming the paper in the vapour of a volatile acid, *e.g.*, acetic acid.

A prussiate paper which also exhibits pronounced resistance to deterioration on being stored in the dark, can be prepared, according to E. Bertsch,[59] by the addition of 10-20 per cent. of an alkali oxalate to an alkali ferric oxalate before treatment with ferricyanide. The colour of the image changes during printing through various shades of green and blue to a yellowish grey, and on washing it is claimed that pure white lines on an intense blue ground are obtained. The preparation of a duplicating stencil by photographic means has been patented by S. J. Walters.[60] The process, which is likely to find a fairly wide application provided a composition is used capable of withstanding the "handling" which the inking imposes, is virtually the transference of a carbon print to a support of fine texture through which the duplicating ink will pass when rolled up in the ordinary way.

A most important step in the sphere of practical photography has been made by the introduction of the so-called "dye impression process,"[60] which is the outcome of several years' experimental work by F. W. Donisthorpe. Briefly, the process consists in making a negative on any suitable base—either rigid, pliable, opaque, or transparent—treating this negative with a solution which induces selective absorption of dye, immersing thereafter in a suitable dye solution, and after a brief rinse, transferring the dye image to a gelatine- or baryta-coated support by a short time contact under slight pressure. The transferred print is then rapidly dried to prevent diffusion of the dye, with consequent loss of definition in the finer details. Apart from the obvious economy and convenience of such a process, it is evident that since only surface images are necessary, only the under-exposure portion of the characteristic curve of the sensitive negative material need be used, and thus an emulsion of ordinary speed (in the H. and D. sense) becomes one of extreme rapidity; the development process is shortened, and the positive results exhibit sufficient accuracy of tonal rendering to allow of the process being applied for most work. In addition, the range of colours of the positives is practically unlimited, being dependent only on the availability of suitable dyes.

Very little has been published relative to the toning of photographic images, but the papers of R. Namais[61] on combined selenium and sulphur toning, of J. Durbreton[62] on the combination of nickel and cobalt ferricyanide, and of J. M. Blaney,[63] who converts the silver image to a tin salt which acts as a mordant for dyes, are worthy of note.

J. W. Pilkington[64] advocates the use of barium sulphide in lieu of "liver" of sulphur in the so-called cold-toning process, which still finds much favour amongst professional photographers. It is claimed by C. Schleussner A.-G.[65] that the brown tones obtained by bleaching a developed print, either before or after fixing, with a solution containing mercuric chloride and potassium bromide and subsequently treating with a hypo bath containing a lead salt, are fast to light. The fastness to other influences is not stated, but previous experience of lead toning processes does not encourage one to place much reliance on the all-round permanence of the toned images.

FOX TALBOT MEMORIAL FUND.

As recently announced in our columns, in a letter from the president, Dr. G. H. Rodman, the Royal Photographic Society is establishing a fund for the purpose of providing a memorial to William Henry Fox Talbot, from whose researches in the early part of the last century the present-day processes of photography have originated. It is proposed that the memorial should take the shape of a stained glass window, to be placed in the church of Lacock, Wiltshire. Lacock has been the home of the Talbots for many generations, and it was there that Fox Talbot carried out his work. The following donations have been received :—Alex. R. Hogg, Belfast, 10s. 6d.; A. E. Mayhew Chatham, 2s. 6d.

FORTHCOMING EXHIBITIONS.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 25 to 30 :—

EMULSION COATING.—No. 19,955. Coating photographic films, paper, etc. Kino-Film Co. and C. Munch.

COLOUR PHOTOGRAPHY.—No. 20,436. Colour photography. Colour Photography, Ltd., and J. F. Shepherd.

COLOUR PHOTOGRAPHY.—No. 19,945. Colour photography. Sir C. S. Forbes.

STEREOSCOPY.—No. 20,175. Optical device to obtain stereoscopic images. A. J. Tonpillier.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AERIAL CAMERAS.—No. 165,181 (March 19, 1920).—The invention comprises the combination with an ordinary aerial camera of

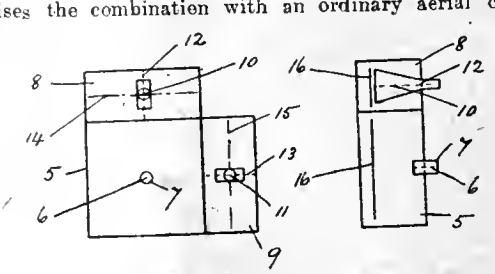

Fig. 2. Fig. 3.

two panoramic cameras having circular focal plnes and mounted so that their lenses swing in planes parallel to the optical axis of the aerial camera, and at right angles or other suitable angle

to one another, across the field which is being photographed, all the three cameras being exposed simultaneously.

If the aerial camera deviates from the vertical when the exposures are made distortion can be detected in the panoramic camera photographs by comparing them with the aerial camera photograph.

In the drawings, the numeral 5 indicates the aerial camera; 6 its optical axis; and 7 its lens. 8, 9 represent the panoramic

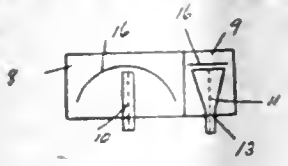

Fig. 2.

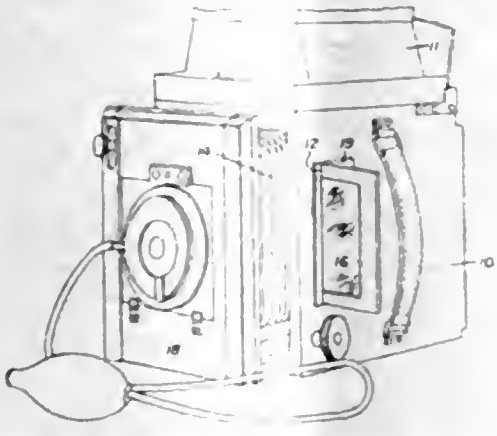
cameras; 10, 11 their respective optical axes; 12, 13 the pivots about which their axes swing; and 14, 15, the planes or paths of movement.

It will be seen that the pivots 12, 13, cross the optical axes, 10, 11, and that the planes 14, 15, are parallel to the optical axes, 6. 16 is the photographic film.—Arthur John Elliott, Instrument Design Establishment, Royal Air Force, Biggin Hill, Kent.

REFLEX CAMERAS.—No. 161,730 (January 29, 1920). By an oversight in the imposition of the pages of last week's issue the



accompanying illustration of the reflex camera patented by Kung-Che Chen, Shanghai, was omitted.

The following complete specifications are open to public inspection before acceptance.

DEVELOPING APPARATUS.—No. 166,697. Film-developing apparatus. H. C. F. Morant.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

S.X. (DEVICE).—No. 403,726. Photographic films and photographic plates, included in Class 1, and made in Essex. Samuel William Copley, Grange Works, The Broadway, Leigh-on-Sea, Essex, manufacturer of photographic appliances.

S.X. (DEVICE).—No. 403,727. Photographic cameras, lenses, and other photographic apparatus, included in Class 8, and all made in Essex. Samuel William Copley, Grange Works, The Broadway, Leigh-on-Sea, Essex, manufacturer of photographic appliances.

S.X. (DEVICE).—No. 401,479. Photographic paper made in Essex. Samuel William Copley, Grange Works, The Broadway, Leigh-on-Sea, Essex, manufacturer of photographic appliances.

STEREOPLASTIC.—No. 401,044. Cinematograph and lantern projection apparatus (included in Class 8), films for exhibition and lantern slides. George Anderson William Hepburn, 44, Chippenham Road, Maida Hill, London, W.9, cinematograph apparatus manufacturer.

NEVILLE AND NEVILLE (DEVICE).—No. 392,025. Photographic paper, photographs, photographic mounts, portraits, postcards and paintings, all being goods included in Class 39. Neville and Neville, 1, Tilley's Chambers, 22, Blackett Street, Newcastle-on-Tyne, art photographers and miniature painters.

SUNIC.—No. 403,331. Chemical substances used in manufactures, photography, or philosophical research. Watson and Sons (Electro-Medical), Ltd., Sunic House, 43, Parker Street, Kingsway, London, W.C.2, manufacturers.

LUMEX.—No. 404,987. Photographic plates, photographic films, and photographic chemicals. Lumex, Ltd., 31, Dame Street, Dublin, Ireland, manufacturers of and dealers in photographic, optical and scientific apparatus.

LUMEX.—No. 404,989. Photographic paper, photographic albums, and photographic mounts included in Class 39. Lumex, Ltd., 31, Dame Street, Dublin, Ireland, manufacturers of and dealers in photographic, optical and scientific apparatus.

ECLIPSE.—No. 413,815. Photographic plates and photographic films. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W.2, manufacturers of photographic materials.

APPLICATIONS FOR REGISTRATION.

TREFOIL DESIGN ("AS DE TRÈFLE").—No. 415,911. Photographic chemicals, plates and films. Grieshaber Frères & Cie., also trading as Société des Produits Photographiques "As de Trefle," 27, Rue du Quatre-Septembre, Paris, France, manufacturers. June 3, 1921.

TEDDY.—No. 415,931. Photographic cameras. Edmond Francis Stratton, 1, Cedar Street, South Norwalk, State of Connecticut, United States of America, manufacturer. June 8, 1921.

Commercial & Legal Intelligence.

LEGAL NOTICE.—Notice is given of the dissolution of the partnership between Charles Stuart, deceased, and Archie Stuart, carrying on business as photographers, at 47-49, Brompton Road, Kensington and 159, High Road, Balham, S.W., under the style of Stuart; at 191, Brompton Road, Kensington, under the style of Searle; and at 169, High Street, Kensington, under the style of Nandin. All debts due to and owing by the late firm will be received and paid by Archie Stuart, who will continue to carry on the business under the same names.

NEW COMPANIES.

CLUB PHOTOGRAPHER, LTD.—This private company was registered on July 30, with a capital of £500 in 500 "A" and 2,000 "B" shares of 1s. each and 1,500 "C" shares of 5s. each. Objects: To acquire the business of proprietors and publishers of the magazine known as the "Club Photographer," carried on at 9, Eberle Street, Liverpool. The first directors are:—G. E. Peachey (chairman and managing director), Beau Desert, Hightown; J. Rowatt, Clifton, Formby; W. H. Gleave, no address given; W. H. Marques, Highground, Heswall; W. G. Reed, 5, Falkland Road, Wallasey. No person is eligible as director unless he is a member of the Liverpool Amateur Photographic Association. Qualification, 100 shares. Remuneration as fixed by the company. Secretary: W. H. Gleave. Registered Office: 9, Eberle Street, Liverpool.

[We understand that the above company has been formed in order to put the business of publishing the "Club Photographer" on an independent basis. The Liverpool Amateur Photographic Association is, through its trustees, a shareholder in the company. —EDS., "B.J."]

MR. W. LANCELOT VINING, the writer of the series of articles, "Photography for the Newspapers," which have just appeared in our issues from July 8 to 29, recently resigned his position as art editor of the "Sunday Pictorial" to take up his residence in the United States, and has now been appointed art editor for the well-known newspaper proprietor, Mr. W. R. Hearst.

New Books.

STUDIO CONSTRUCTION.—In devoting an issue to the design, construction and equipment of photographic studios, the editor of the "Photo-Miniature" has had the good fortune to enlist the services of Mr. Drinkwater Butt, who, as a professional architect as well as a photographer, writes with an authority on this subject such as few may claim to possess. It is inevitable that the ground traversed by Mr. Butt should be much the same as that of the little manual, "The Portrait Studio," issued by our own publishers. The difference in treatment between the two, is, however, quite sufficient to justify the purchase of one manual by these who already have the other. The issue, which is No. 182, is published in this country by Messrs. Houghtons, price 1s. 8d.; in the United States by Messrs. Tennant and Ward, 103, Park Avenue, New York, price 40 cents.

PHOTOGRAPHIC ABSTRACTS.—The second issue of this quarterly publication of the Scientific and Technical Group of the Royal Photographic Society shows the compilers getting into their stride. The issue contains 260 abstracts (as compared with 97 in the first issue) of articles, communications, patent specifications, etc., relating to the various branches of photography, cinematography, radiography and photo-mechanical processes. A great deal more than painstaking industry is displayed in the preparation of this *résumé* of current progress in these widely scattered fields of work. Mr. B. V. Storr, M.Sc. F.I.C., who has been appointed editor, shows a refined sense of proportion in the space which he allots to the abridgments of the various items, and makes excellent use of variations of type-setting in pursuing this policy. Although the publication lays itself out to record the more recondite papers dealing with sensitometric methods and with the theory of photographic process, it must not be ignored that new devices and methods of practical photography occupy a considerable proportion of its pages. For example, the current issue traces, in a series of abstracts, the stages of the process of desensitising plates for development in white or bright light, from its initiation by Dr. Lüppo-Cramer during the course of last year. Other "practical" items relate to the toning of prints, and we are interested in noticing that a French patent has been taken out for the use of sulphoxy-phosphates as odourless substitutes for sulphide in the sepia toning process. It is scarcely too much to claim for the publication that it puts before the student in a compact form the subject matter of the photographic and scientific Press of the entire world which comes within the scope of "photography," employing that term in the widest possible sense. Moreover, the exact bibliographical form of the abstracts enables the student to consult the original sources of publication. The Scientific and Technical Group of the Royal Photographic Society need not point to any other work than that which it has accomplished in this publication in order to justify its formation, or to claim a still larger measure of support by members of the Society. Members of the Group receive "Photographic Abstracts" as one of their privileges of membership. Those who are not within its membership may obtain "Photographic Abstracts" post free for 10s. per annum, or for 2s. 8d., post free, per single issue.

PHOTO-ANALYSIS IN THE COMMERCIAL WORLD.—Employers advertising in the "situations vacant" columns of the daily Press appear now to be making it a rule to ask applicants to send their photographs. Years ago "Please send photo., which will be returned," was a request somewhat rare, but it is common enough to-day, as undoubtedly a photographic portrait gives an impression of personality which a letter alone cannot always give. A writer in the "Daily Chronicle," who calls attention to the growing demand for portraits, states that in the United States the alert business man has gone a step farther. He has a photograph filed with the correspondence of all members of his staff with whom he is in regular touch only by letter. So when the chief in New York writes to his traveller Smith in Arkansas he calls for Smith's photograph as well as Smith's last letter. From the photograph he sees again what manner of man Smith is, and tunes his communication according to Smith's enthusiastic features or—if it be Jones—in a sergeant-major vein.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, AUGUST 16.

Hackney P.S. "Snow Photography." W. Selfe.
Scottish C.W.S.C.C. (Glasgow). Lecturette.

WEDNESDAY, AUGUST 17.

Bradford Phot. Soc. Evening Excursion to Calverley or Rawdon Woods.

THURSDAY, AUGUST 18.

Manchester Amateur Phot. Soc. Ramble to Mobberley.
North Middlesex P.S. Outing—Wimbledon Common.
Scottish C.W.S.C.C. (Glasgow). Outing to Carmunnock and District.

CROYDON CAMERA CLUB.

MR. H. P. C. HARPUR trod the boards last week, the event being notified by a secretarial illustrated announcement in colours on the notice board. It is reproduced on a greatly reduced scale as a

typical example of Mr. Sellors' way of intimating future events, and also as an excellent likeness of the wizard depicted, albeit somewhat dwarfed as regards portions of his pictorial person.

Mr. Harpur chatted on several subjects, not consecutively in hackneyed fashion, but in interwoven manner, rendering it difficult at times to unravel the threads of coherence. One learnt at the start that he habitually uses tabloids to assist operations, and they certainly seemed to give uniformly good results. The word "tabloid," he was careful to point out, is the "patented" trademark of Messrs. Burroughs and Wellcome, and denotes a compressed preparation, which may be handed down as an heirloom without fear of deterioration.

He had recently tried their new sepia toner and found it very good, one tabloid being sufficient for at least six 10 by 8 prints, and possibly many more. The action is slow, enabling toning to be stopped at any required stage, and with subjects not presenting much contrast (when "double-tones" may be pronounced), very effective cold tones are possible, in addition to warm ones secured by full toning. The smell of the sulphide solution, he said, is but little apparent, provided the nose is not used as a stirring rod. He then toned some prints which were much admired, though the non-production of sample tabloid-toners damped appreciation somewhat.

He next showed the local reduction of bromide prints with ferricyanide, clearing away the background of a portrait taken by him. It was much admired by one person in the room.

In the discussion, referring to an observation of Mr. Harpur's that most professionals do not care a naughty word whether their prints last or not, Mr. Berry buried the allegation with a shovelful of indignant disclaimer. Mr. Walker had found that bromide prints, reduced with ferricyanide, had miserably perished. Disaster is invariably associated closely with Mr. Walker, who ever preserves a cheerful deportment under adversity. Mr. Salt had found prints locally reduced eventually yellow at the parts treated. In

all cases after reduction, it is, he said, a wise precaution to pass the prints through a clean fixing bath without preliminary washing. Mr. Purkis agreed. A most hearty vote of thanks was accorded Mr. Harpur for one of his inimitable expositions. Never does he afford a dull evening.

News and Notes.

MULTUM IN PARVO ADVERTISING. We clip the following advertisement from an American newspaper: "Want a camera? Then I've got it. You've got one? Then I want it." Then follows the name and address of the camera store.

STUDIO ARC LAMPS.—The General Electric Company is issuing a semi-enclosed type of arc lamp designed for studio portraiture. A circular containing a full specification of the lamp and accessories is obtainable from the company, 92-4, Queen Victoria Street, London, E.C.4.

VERASCOPE CAMERAS.—The City Sale and Exchange, 81, Aldersgate Street, London, E.C.1, inform us that they have made a 20 per cent. reduction in the prices of Verascope cameras, that is to say, in the goods listed on pages 4 to 8 of their 32-page price list of Richard manufactures.

STOLEN CAMERAS.—A well-dressed youth, described as a clerk, was remanded at the Guildhall last Saturday upon a charge of being a suspected person. It was stated that when searched at the police station there were found on him a Kodak camera, a gold and a silver wristlet watch, gold-rimmed eyeglasses, a gold albert, silver match-box, and a gold cigarette-box. Asked where he got them accused replied "Stole them." A detective stated that there was also a reflex camera among some other property accused had stolen.

THE CLUB PHOTOGRAPHER.—The August number of our Liverpool contemporary derives its literary and pictorial contents from members of the Leicester and Leicestershire Photographic Society. Mr. A. E. Baker writes on photographic record and survey; Mr. W. Bailey on elementary photographic optics; Mr. Frank W. Beck on the photography of stained glass; and Mr. H. R. Dickens on composition in landscape. Our contemporary is published at the headquarters of the Liverpool Amateur Photographic Association, 9, Eberle Street, Liverpool, price 3d. monthly.

HELPING THE MALE FORM.—It is now so long since we had any radical change in man's dress that efforts are being made by fashion moogers to revive the cloak, one of the reasons given being that it "photographs so well." Another writer says: "It (the cloak) is a most elegant garment, as all who go to that wonderful film play, "Dr. Jekyll and Mr. Hyde" can see. Notice how attractive Dr. Jekyll looks in his swinging cape. What a graceful swagger it gives him. Few men carry themselves as well as they did in the old days, and I believe the cape was responsible for much."

AERIAL PHOTOGRAPHY IN HYDROGRAPHY.—Attention is called to the importance of the paper submitted to the French Academy of Science by M. Volmat, in which he gives particulars of aerial photographic experiments carried out from a hydro-airplane, and emphasises the importance of such a method in drawing up sea charts, so as to obtain quickly and exactly particulars relating to the lay of the coast, the conformity of shoals discovered at low water, etc. In the tests carried out, 17 metres below zero on the chart was the greatest depth at which the bottom could be clearly seen. Great depths produce a characteristic surface movement of the waves. From the impression on a photographic plate of wave action it has been possible to discover a point of rock 8 metres below zero.

MISTAKES IN HAND CAMERA WORK.—The difference in the results obtained with a hand camera by a skilled user and those which commonly fall to the lot of the tyro is exceedingly well illustrated in a lengthy article in the current issue of "Conquest," by Mr. D. Charles. Selecting the subjects to be encountered on the Thames Embankment between Charing Cross and Westminster, he is at pains to show the difference in effects obtainable by correct observance of the ordinary elementary precautions in focussing, setting the shutter, choosing the view point and lighting, etc. In the notes which accompany the many reproductions of photographs, Mr. Charles has a good deal of useful advice to give to the tyro in hand-camera work. Beginners in photography will study this issue of "Conquest" (Wireless Press, Ltd., 12-13, Henrietta Street, price 1s. monthly) with a great deal of interest on account of this item alone, and will at the same time make the acquaintance of a magazine which deals in a popular but accurate way with many aspects of science and industry.

A.P.M. TRAVELLERS.—Messrs. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, announce that from August 1 last the three component companies of Marion and Co., Paget Prize Plate Co., and the Rajar Co., will be represented by the following nineteen travellers allocated to the districts named. Those calling on professional photographers are:—London: A. Smith and G. E. Perry. South-East and East Coast and Channel Isles: F. E. Jones. South, South-West, and South Wales: H. Freckleton. Midlands and Lincs.: J. M. Dickinson. North-East, North-West, and Yorkshire: A. C. Freckleton; Lancs., North Wales, and Isle of Man: J. W. Freckleton. Scotland: R. Whaley. Ireland: O. C. Hackett. Those calling on photographic dealers are:—London: G. A. Heed, B. F. Crane, A. R. Shea, and J. H. Beavan. S.E. and E. Coast: A. D. Hunt. S. and S.W. and S. Wales: W. A. Lewis. Midlands and Lincs.: E. D. Jones. N.E., N.W. and Yorks., E. S. Rowbotham. Lancs. and N. Wales: A. W. Muncaster. Scotland: T. E. North. Ireland: O. C. Hackett.

AERIAL PHOTOGRAPHS FROM CRANE BUCKETS.—A correspondent, who a few days ago was asked (but refused) to ascend in one of the buckets attached to one of the largest cranes now working in London, was shown a cutting from an American magazine in which, he says, was an illustrated account of how New York photographers work from a crane hoist. Aerial photographs of ship's decks, and bird's-eye views of the whole construction plant, are, it appears, taken without the aid of airplanes or balloons. A board seat slung from the hooks of a big crane constitutes the photographer's base of operations, and in this small cockpit, armed with a camera, he is swung aloft to any altitudinous viewpoint he may select. In further resemblance to a flier, he is fastened in, the function of the stout rope around his body being not so much to increase his security as to afford him full and free use of his hands in focussing and making the exposure. Because the location may be studied, or changed on signal to the engineer, views are obtained this way that could not be taken even from a plane, and in the American magazine were reproduced many fine examples of "crane tripod" work.

Correspondence.

*** *Correspondents should never write on both sides of the paper.*

No notice is taken of communications unless the names and addresses of the writers are given.

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

MR. TILNEY.

To the Editors.

Gentlemen,—Thank you for your "Notes and News" paragraph of August 5. May I say to your kind correspondent that I have "been doing" nothing in Sydney. (How I should have enjoyed myself amongst the music, laughter, eats, drinks, and smokes of the soft folkers' evening!) My explanation of the inquiries of Messrs. Paton and Wakeford is that someone wanted to hand me conscience-money as bonus—*extra* fee for my course.—Yours faithfully,

F. C. TILNEY.

Art of Life Movement, 28, John Street, Bedford Row, London, W.C.1. August 5.

D-50 DEVELOPER.

To the Editors.

Gentlemen,—We have read with interest the report of the meeting of the Croydon Camera Club, at which Mr. E. A. Salt brought to the notice of the members our new developer D 50 (see page 466 of your issue of August 5).

Much as we should like to touch upon the many interesting points raised at the meeting, we feel a diffidence in encroaching on your valuable space.

Will you allow us, however, to refer to Mr. Salt's comment on our claim that D 50 "owes its unique properties not alone to the

careful blending of certain standard forms of reducing agents, but principally to the incorporation of agents *new to science.*"

We are much amused at Mr. Salt's suggestion that this wording would excite the envy of the vendor of a hair-restorer. We have not, so far, launched a new hair-restorer, but, if and when we do, we shall not scruple to emphasise the fact that it contains agents "now to science," if such be the case.

Strange as it may seem, it is nevertheless true that D 50 does contain such components.

Is not this fact substantiated by Mr. H. W. Berry's statements, mentioned in the last paragraph of your report, that "no other developer was capable of the feat illustrated by Mr. Salt's set of bromide prints"?—Yours faithfully,

For and on behalf of
THE COOPER LABORATORY
(Chemicals and By-Products, Ltd.).
H. E. LAWS, Managing Director.

Watford, August 9.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. P.—Usually it is not thought necessary to lead-line a teak tank; the wood itself is practically impermeable, and if the tank is well made it will keep watertight for as long as if lead-lined

R. H.—So far as we know there is no method which is really satisfactory in practice of using bromide or gaslight postcards in the same way that ferrotype cards or buttons are employed.

H. S.—The best way for the quick drying of negatives is by one or other of the methods mentioned in the Almanac, p. 433. Bromide paper requires to be handled by a deep orange or bright red light. It is not safe to handle it by white light like gaslight paper, nor even by very bright yellow light.

E. W.—If the room is of moderate size a single 1,000 c.p. lamp will suffice for head and shoulders or three-quarter length portraits, although we would sooner have 2,000 or 3,000 c.p. for greater ease of working. Yes, the light should be diffused. Usually a moveable head screen of muslin mounted on a hoop, and capable of being adjusted in position between the lamp and the sitter, is sufficient for single figures.

W. B.—We have little doubt that the severity of the speckled markings on the prints is due to the exceptionally hot weather. For avoidance of these markings it is advisable to wash the prints for the minimum of time after the hypo bath, or if this cannot be done on account of the size of the batches, to let prints dry and give them a soak in water only just long enough to make them limp before squegeeing on the glasses.

H. E. R.—If you wish the most effective means for minimising retouching marks in the enlargements you should discard the condenser and illuminate the negative entirely by reflected light. For this purpose a box of, say, semi-circular shape can be fitted up behind the negative and illuminated by, say, four 500 c.p lamps. The interior of the box should be painted matt white, and this coating renewed as it becomes discoloured.

M. E. T. W.—According to the "Pharmaceutical Journal," a method of keeping cut flowers fresh is as follows:—The flowers are first well sprinkled with fresh water and then placed in a vase filled with the following solution:—Hard white soap, 1 oz.: sodium chloride, 50 grs.; water, 34 ozs. The soap is shaved and dissolved in water, and the salt is then added, this causing a slight gelatinisation of the solution. Finally, a very little boric acid is dissolved in the liquid. The flowers are taken out every morning, the foliage washed, and then put back in the vase. The solution is renewed every three days. Flowers thus treated will keep in good condition for two weeks.

E. M.—A formula for a combined developer-fixer for ferrotype plates is as follows:—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs.
Liq. ammonia, .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo.

C. E. B.—For filling the marks of scales, such as those used on hand-cameras, etc., a very suitable material is a mixture of lamp-black and tallow. A little tallow is melted in a small tin or pot and, while fluid, thoroughly mixed with enough lamp-black to make a thick paste. This will set quite stiff, and will keep indefinitely. When required for restoring engraved scales, a little of the mixture is taken on a knife blade or small spatula and spread over the engraving, pressing it well into the cuts. It is then rubbed off with a piece of smooth rag, and the last of the grease finally cleaned off with a wet rag rubbed on a piece of soap. If the engraving is on metal or celluloid no other precaution is required, and if on wood there is no fear of smearing the surface unless the wood is rough and unpolished.

F. W.—(1) The sitter having accepted your invitation, the copyright in all negatives taken at the sitting belongs to you. (2) In the absence of any undertaking in writing, or in a verbal manner, which can be confirmed, the sitter cannot demand a fee for sitting in the event of Press reproduction. (3) Yes, it is a free sitting, and therefore the copyright is your property, and you are not deprived of it by afterwards supplying copies to the sitter for which she pays. (4) The sitter and the other photographer are equally liable in respect to infringement of your copyright. You can take action in a County Court for delivery of infringing copies and also for damages in respect to the infringement. We suggest that you would derive a good deal of information on these questions of copyright from the manual on "Photographic Copyright," which we issue.

H. R.—With a 4¾ f/4.8 lens you certainly ought to get sharp definition of a subject receding from the foreground into the distance at a much larger aperture than f/22, say, f/6 to f/11. We shouldn't expect sufficient depth at anything larger than f/6, and that is rather large for a subject of the particular kind you mention. Are you sure that it is diffused definition due to insufficient depth of focus? Your second question suggests that it may be due to shake of the camera. For such subjects we should focus at a distance of about 50 ft. away. No means of gauging such a distance, except by practice in "pacing it out." We are sorry we cannot think of any remedy for prevention of vibration in holding the camera. Small pinholes can be temporarily stopped out by applying rubber solution mixed with lamp black, but in the long run it is best to have a new blind fitted.

Contents.

SUMMARY

Mr. A. H. Hall, in a contributed article, shows the good use which can be made of a small camera for at-home domestic portraits of a kind which are secured only with great difficulty in any other way. (P. 487.)

An American worker has described a combined flash and electric lamp, which he has found of special value in the making of portraits of young children. (P. 488.)

In a leading article we refer to the means for avoiding sharply cut-out outlines in portraiture. In consequence of optical exigencies, such means will usually involve a certain amount of diffused definition. (P. 486.)

Thermit discusses the facts requiring to be faced as regards amateur competition in portraiture. (P. 489.)

A method of economising frames, used for the display of specimens, is described by a contributor to "Assistants' Notes." (P. 492.)

The young professional is cautioned against starting a portraiture business on a cut-price basis. (P. 486.)

A portable outfit ready for use at a moment's notice is a piece of photographic equipment of which profitable employment can be made. (P. 486.)

For the copying of sepia prints an orthochromatic or panchromatic plate and a large-aperture lens will go far towards securing satisfactory results. (P. 486.)

In the concluding part of his review of recent progress in photographic manufacture, Mr. Raymond E. Crowther deals with cinematography, and with methods of sensitometric measurement. (P. 490.)

A correspondent suggests a system of rating bromide paper for contrast which might be applied commercially. (P. 499.)

Mr. Julius Rheinberg has patented a sensitive collodion mixture containing an iron salt and employing methyl alcohol as the solvent of the pyroxyline. (P. 493.)

Mr. E. J. Wall quotes references to the early literature of photography with magnesium light, showing the English priority in this invention. (P. 497.)

The Eastman Kodak Company have declared 7½ per cent. on the common stock, in addition to the usual quarterly dividend of 2½ per cent. (P. 495.)

A canvasser, who took money for colouring photographs but did not supply the goods, was sentenced to hard labour at Canterbury Police Court last week. (P. 495.)

Methods of making screens for cinematograph projection in daylight have recently engaged the attention of several inventors. (P. 493.)

A new type of anastigmat lens is the subject of a recent patent specification. (P. 492.)

Looseness of the lens elements in their cells may be a cause of defective definition in hand-cameras fitted with large-aperture objectives. (P. 485.)

EX CATHEDRA.

Small Stand Cameras. Considering the excellent results that are obtained with cameras of the "snapshot" variety, it is rather surprising that comparatively few skilled workers employ small cameras for architectural and other work which calls for the use of adequate rising front and swing-back adjustments, together with a great range of focal lengths. A few years ago it was difficult to obtain either very short or very long focus lenses, of good quality, in sizes which could be adapted to quarter-plate cameras, but it is now possible to procure such lenses for even smaller-sized plates. One of the most celebrated explorers has pinned his faith on a quarter-plate long-extension camera, fitted with lenses ranging from three to thirteen inches focal length, with the addition of a telephoto attachment, and has secured, with the minimum of weight and expense, many hundreds of almost priceless negatives. Most small-stand cameras of the Una or Sanderson type are equally available for use in the hand, and if a film-pack adapter be carried, all classes of work can be dealt with. It is, of course, very necessary that a firm tripod be used, as the best of cameras and lenses are worthless if used upon a flimsy metal stand.

* * *

Cause of Unsharp Negatives. Those photographers who use hand cameras fitted with large-aperture anastigmat lenses should always make sure that the lens components are screwed well home into the mount or shutter casing after they have been taken out for cleaning. If this point is not attended to, negatives may be produced that are not quite as sharp as the lens is capable of producing. An instance of the necessity for care in this direction was brought under our notice recently. The trouble was one of unsharp negatives taken with a hand camera fitted with one of the best known unsymmetric anastigmats. The lack of sharpness was not very pronounced, and only detected after enlargements had been made, or the small negatives carefully compared with others taken previously, that were entirely satisfactory as regards sharpness. This pointed to inaccurate register, but a careful test showed that this was not the case. It was then noticed that the lens components fitted very loosely in their mount, and it was eventually shown that after the camera had been carried for some distance the components altered their positions slightly, which accounted for the loss of definition in the resulting negatives. Another point that needs to be kept in mind, when removing and replacing lenses of this type, is that the instrument, as a whole, is intended to be employed with its components inserted in a certain manner, and this should be rigidly adhered to. We have an unsymmetric anastigmat in our possession that is an example of this. Changing over the back combination to the front, the instrument requires

the front to be at least two inches further away from the ground glass than when the lens is assembled in the correct manner.

* * *

Fatal Cheapness. One of the most insidious pitfalls which beset the path of the young photographer is the idea that a successful business can be built up by charging prices which are lower than those of his established rivals. It should always be borne in mind that it is much more difficult to obtain decent prices after working for low ones than it is to do so from the beginning. We have had many opportunities of watching the starting and progress of young professionals, and can say with confidence that those who have adopted the highest scale prevalent in their neighbourhood have been more successful than those who have begun by "cutting." The reason is obvious. The established man has a larger clientele, and therefore his running expenses are not so heavy in proportion as those of the beginner, who is therefore tempted to economise in materials and labour to the detriment of his work. Naturally, the work offered must be worth the price asked for it, and therefore our beginner must choose a locality in which his productions will be up to the standard of the neighbourhood. In our experience, given a good class of work, customers do not take notice of even a substantial difference in price.

* * *

Copying Sepia Prints. It is much more difficult to copy sepia-toned bromide prints than black and white or P.O.P., there being usually much loss of detail in the shadows. This is due to the non-actinic colour of the image, which at a certain depth of deposit practically ceases to have any effect on the slow ordinary plates which are usually employed for copying. For this reason, orthochromatic or, if to hand, panchromatic plates should always be used for such subjects. As there are no colour contrasts, a light-filter is not usually needed, although it will minimise the effect of surface reflection. It is always desirable to use as large a lens-aperture as will give the desired definition, as a small stop always tends to give a more contrasty result. For the same reason, a strong light should be used to illuminate the original, even direct sunlight being suitable for very dark prints. Those who have had little experience in copying will find it instructive to make a strip exposure pulling out the slide an inch at the time, so as to give exposures in the ratio of 1, 2, 4, 8, and so on. A first-class result is then ensured upon a second plate exposed for a time equal to that given to the correctly-exposed strip.

* * *

Be Prepared. A common failing of many photographers who are mainly occupied with portrait work is a lack of readiness to undertake a "rush job" as a moment's notice. It sometimes happens that a record is required of an accident or, perhaps, a crime, when every moment is precious, and if there is any delay caused by having to collect the various items of an outfit, or by reason of the apparatus being too heavy or bulky to be transported with ease, the opportunity is lost, to the annoyance of the would-be customer and the pecuniary disadvantage of the photographer. To avoid such contingencies it is well to have a small camera, say, postcard of half-plate size, ready to pick up and carry out. Even the filling of slides causes needless delay, so that roll film or a film pack is to be preferred to plates, as film does not deteriorate so rapidly as plates do in many slides. A postcard-sized film camera is very suitable for this class of work, and it should be provided with a light tripod. Snapshotting should be avoided, the lens being well stopped down, and time exposures given, so as to get negatives which are well exposed and full of detail. The absence of a swing-back is a disadvantage, but it will be found that it is rarely required in this class of work.

DEPTH OF DEFINITION IN PORTRAITURE.

At first sight it may not appear that "depth" in portraiture differs in any way from that required by any other class of subject, and when sharply-defined negatives, printed upon glossy paper, were almost universally used, this idea would be fairly correct. But now that the technique of portraiture is so widely different from that of ordinary commercial work, any methods of obtaining soft, yet even, definition over several planes are worthy of consideration.

In the ordinary way, depth is obtained either by manipulation of the swing-back or by reducing the working aperture of the lens. By the first of these expedients there is, of course, no real gain in depth of definition. All that has been done, is to have accommodated the plane of the plate to the plane of the subject when this is not normal to the axis of the lens. It is usually employed upon sitting figures, where the knees or feet are much closer to the lens than is the head. It has the defect of introducing violent perspective; that is to say, the hands or feet, usually large enough in nature, are reproduced on a larger scale than the head. As a rule, the best results are obtained by using the old type of portrait lens, which has a curved field, as this will help to give good definition of the waist and bust. With a flat-field anastigmat of the same focal length and aperture, the knees or hands and the face will be well defined, but the intervening portions will lack definition. With large heads, where the neck or collar is unsharp when the eyes are focussed for, the swing-back is practically useless.

If we reduce the aperture of the lens we can obtain any required depth at the cost of prolonging the exposure, and that without interfering with the correct perspective from any given distance, but we now find that the definition of certain portions of the subject is too sharp for modern tastes. We must therefore seek a means by which it is possible to secure depth and softness at the same time. Probably the best way of doing this is to employ a lens which at full aperture will give very soft or even "fuzzy" definition, and to reduce the size of the diaphragm until a satisfactory result is obtained.

There is quite a variety of suitable lenses, some of which produce soft images, in consequence of the presence of spherical aberration alone, while others introduce chromatic aberration, as the well-known Bergheim lens and the French anachromats. Most photographers will probably choose one of the adjustable soft focus lenses, of which the Aldis *f*/3, the Cooke portrait lens, and the Dallmeyer "patent" portrait lenses, all of which have the advantage of being adaptable to sharp as well as to soft-focus work. One important point must not be overlooked; it is that by reducing the lens aperture the softness due to spherical aberration is also reduced, absolute sharpness being usually obtained at an aperture of *f*/16. So small an aperture is not likely to be used for portraiture except with very large heads, but care should be taken that the initial amount of spherical aberration should be large enough to leave a serviceable residue at *f*/11.

Simple uncorrected lenses, *e.g.*, the "spectacle" lens of the artistic landscape worker, are worth consideration

now that plates with a speed of 500 H and D are in daily use. As they are already of small diameter they will usually give the desired effect without a diaphragm, but it is necessary in most cases to make an allowance when focussing to eliminate some of the chromatic aberration.

Mechanical methods for softening the definition of a lens which gives uniformly sharp negative have received considerable attention when applied to enlarging, but have been neglected as far as the making of portrait negatives is concerned. It would be interesting to test the applicability of the diffusing discs, as supplied with the Eastman vertical enlarger, to portrait work, and even to use chiffon or bolting silk near the lens or in front of the plate. Many years ago we experimented with a black gauze screen midway between the lens and sitter, but the results were not satisfactory, doubtless owing to the choice of position.

We have lately seen some excellent results produced by the use of a cross-lined process screen, used in close proximity to the lens, and further experiments in this direction are being made by one of our most skilled technical workers. The texture of the screen has a considerable effect upon the degree of definition, and various rulings are being tried.

It may seem as if this article were devoted to obtaining soft focus effects, but that is not its object, which is to overcome the unpleasant "cut-out" appearance which results from stopping down to obtain sufficient depth throughout the whole composition.

THE POCKET CAMERA IN AT-HOME PHOTOGRAPHY.

In a recent issue reference was made to the possibilities of photography inside and out of a private dwelling as a means for increased business. The proposal made was for the production of a simple album of the customer's surroundings, and it is equally likely that intimate pictures of the inhabitants would be as acceptable.

If it is not considered presumptuous on the part of an amateur, who has specialised in his own home, it is thought that some of his experiences may be useful. Amongst other subjects, a series of prints, taken at intervals of roughly a fortnight, of a baby has given much pleasure, and many mothers, seeing prints of this nature, could not resist the suggestion that a series of her baby be taken, say, once a month. The baby is, perhaps, the most difficult subject likely to be encountered, and it may be well, therefore, to deal with the details.

A very young baby will permit of a time exposure, but after about three months the difficulties increase, and some of the portraits were taken out of doors. Latterly, however, it was decided to try what could be done with a hand camera in the house. It may be mentioned that none of the rooms had light surroundings, with the exception of a small bath room, which faces north. As in no case were any elaborate steps taken, the conditions described may be considered as representing about the average which would be likely to be encountered.

It was found with the extremely fast plates now available that with a lens working at *f* 4.5 in an ordinary room with one window, dark floor covering, and yellow wallpaper, an exposure of one-eighth of a second gave a fully exposed negative at mid-day in March, the subject being about 4 ft. from the window. At this exposure it was found that the number of failures due to movement were very few. Subjects which were particularly admired were taken in the evening when the ceremony of bathing the baby was in progress. The room faces north, but with the reflected light of an enamelled bath and light wallpaper, if the subject were facing the light, an exposure of one-eighth of a second, or one-quarter of a second against the light, gave good results at six in the evening in the early part of April, the full aperture *f*/4.5 of the lens being used.

The space in which to operate is extremely restricted in the average bathroom, and may be in other rooms, so that the advantages of a pocket camera with a good lens and a reliable shutter, are apparent, and all exposures of a quarter of a second or less were made with the camera held in the hand. Even if longer exposures are required for some subjects, a pocket camera permits of an easily devised support; and in the case of a baby in his bath speed of working is essential; even if the space permitted of a stand, it is likely that it would be in the way.

It will often be necessary to take the child within 4 ft. of the camera—more is not possible in the bath, and at such a distance accurate focussing is essential. The writer is not above the use of a knotted string to indicate distances in feet in these circumstances. It is unnecessary to enlarge on the possibilities of distortion with a camera as near the subject as this, unless due care is taken.

A further advantage of the small pocket camera is, of course, the depth of focus of the lens, and sharp negatives are obtained with ease in restricted corners of the house or garden, where, with a larger camera, this result would be obtained with difficulty.

In the writer's experience, much interest is taken in photographs of specimen plants in the garden, and the small camera permits of sufficient depth of focus with a stop of *f*/8 for near objects. This will, of course, permit a hand camera exposure in a good light with a fairly deep screen and a panchromatic plate.

It is advisable to carry a supplementary lens (often called a portrait attachment), so that small objects at about 2½ ft. distance can be taken.

Special reference has been made to the baby as possibly the most difficult subject. It is obvious, however, that the other inmates should provide further work.

It is suggested that proofs might be submitted on postcards, and if the writer's experience as an amateur is any criterion, many of the successful prints will not only be used for the portfolio or album, but a dozen copies on postcards for friends and relatives will be required; in fact, the popularity of some of the more intimate subjects has caused considerable embarrassment to a photographer with very limited time at his command.

Even where it is proposed to use a half-plate camera, a duplicate taken with the pocket camera may save a failure, and it is not uncommon to discard the larger negative in favour of an enlargement from the small one. In these days of high prices the saving in material is not unimportant.

As the small negatives will invariably be required for enlargements and a total absence of fog is most desirable, the writer uses Desensitol, which enables full examination of the tiny negative with safety. The possibilities of this work have only been broadly indicated, but many subjects will present themselves which are well worth the exposure of a tiny plate where some hesitation would be evinced in using larger plates.

A. H. Hall.

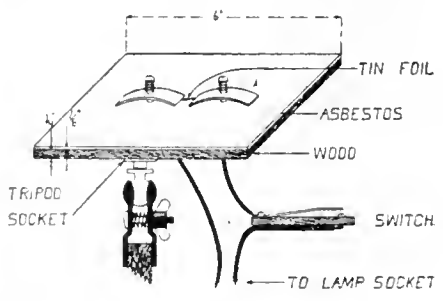
A COMBINED ARC AND FLASH LIGHT.

[In the current issue of "American Photography" a contributor, Mr. Perley H. Fuller, describes the construction of a portable artificial light outfit, in the use of which an electric flash is obtained simultaneously with the ignition of a charge of flash powder. The author appears to be satisfied with the safety of this appliance—at any rate, he makes no mention of danger attaching to its use—but it certainly seems as though the employment of ordinary house current for this purpose involves very great risk of blowing out the fuses, if nothing worse.—EDS. "B.J."]

ANYONE who has tried to get a set of good pictures, having as the principal subject a small baby, say, from a few months to two years old, will agree that it is not an easy thing to do. The professional photographer, using a fast lens and expensive equipment, may get a good picture at every exposure. But for the amateur, with a roll film camera and lens working at *f*/8, the average of good pictures would be nearer one in ten. Perhaps the picture is attempted in the house. It would probably be found that to give exposure enough to the negative, with the lens wide open, would require from 3 to 4 seconds, even near a window. An exposure of this length, on such an active subject as a baby, can have but one result, viz., movement in the picture nearly every time. If we take the baby out of doors, where the light is stronger, in order to shorten the exposure, indifferent results are secured because of the strong lighting on the face, which cannot be controlled.

The writer of this article, using a piece of home-built apparatus, costing less than $2 is able to take a baby picture in any room in a house, with a certainty of getting a picture ninety-nine out of one hundred times.

The apparatus to be described uses a light which is a combination of electric arc and magnesium flash. It is free from the troubles occasioned by using an ordinary flash, and will not scare the smallest child. The intense light of the arc, helped by the magnesium powder, gives in one one-



hundredth second the necessary light for full exposure. The subject can be caught in any pose, and the light is under perfect control.

The apparatus, as illustrated, consists of a piece of dry, hard wood board, 6 in. square and ¼ in. in thickness. The top of the board is covered with a piece of sheet asbestos ⅛ in. thick. This can be fastened to the board with narrow strips of sheet brass, drilled for screws and running around the edge of the sheet, held by small round head brass screws.

Two strips of springs, brass, ½ in. in width and 2 in. long, are drilled in the centre for the passage of a wood screw and curved as shown. The screws should be of brass, about 1½ in. long, and are used to attach the brass strips to the board. They come entirely through the board, and the wires leading to an ordinary lamp socket plug are soldered to them beneath the board. A short piece of coiled brass spring on each screw helps to hold the curved strips of brass firmly against the asbestos.

The under side of the board is fitted near one edge with a tripod socket, and into this socket is screwed a tripod attachment of the universal type. This allows for attaching the apparatus to almost anything, such as the back of a chair, edge of a shelf, etc.

A simple switch for firing the flash is built into one of the wires connecting with the electric light current of the house. This switch may be a piece of wood, some 3 in. in length; a small screw through one end serves as one contact and one wire is soldered to the point of the screw, where it comes through the wood. The whole thing is then wrapped with electrician's tape, exposing just the screw head, and binding the wire tightly to the wood.

A piece of spring brass is then fastened in place over the screw head, and the other terminal is soldered to it. A wrapping of tape applied loosely over the whole switch prevents the operator from getting a shock, and at the same time is flexible enough, so that the spring of the brass holds the circuit open, unless closed by the operator.

About 10 ft. of ordinary double lamp cord, such as is used in house wiring, for drop lights, is used to connect the flash to the 110 or 220-volt light circuit of the house, by means of the usual plug, to screw into a lamp socket. Any voltage works equally well. The switch should be wired in about midway of the lamp cord. In operation, a small strip of tin-foil, cut with the print trimmer from the foil used in wrapping roll films, is placed on the asbestos between the two curved brass strips, which clamp the foil under pressure to the asbestos. The separation of the strips is about ¾ of an inch. The foil should be a little less than ⅛ in. wide, and never more than a single thickness used.

In setting up the flash for an exposure, the plug attached to one end of the lamp cord is screwed into the nearest lamp socket, making sure that the current is turned on. The position of the subject is chosen, and the camera, which we will assume to be a roll film type, with *f*/8 lens, is placed about 8 ft. from the subject, focus set at 8 ft., stop between *f*/8 and *f*/11, and shutter at bulb. The flash apparatus, after being connected to the current, is clamped in position, perhaps to a stick tied to the back of a chair or any handy support. The tin-foil is put in place, and about half a teaspoonful of any good flash powder piled on the foil. Care should be used to tilt the flash board, so the light will not be shielded from the subject. (It should be mentioned here that the photographer admits full daylight to the room in which the picture is taken. This cuts down the apparent brightness of the flash, so that it is hardly noticeable, and prevents the staring look seen in some flash pictures). Taking the camera bulb in one hand and the flash switch in the other, the operator awaits a favourable time for the exposure. An assistant can place the baby, and as there is no hurry about making the exposure, the baby is allowed his time to fall into a pleasing and natural pose. At the proper instant the photographer presses the camera bulb with one hand, opening the shutter and holding it open, then presses the flash switch, held in his other hand. The flash fires instantly, and the shutter is then closed. Anyone used to the outfit would probably not have the shutter open over half a second in all, and for this reason—full daylight can be used in the room as mentioned.

The flash itself is caused by the current fusing the small strip of foil. An arc is formed where the foil breaks, and under its heat the foil is converted to a metallic vapour. This gives an intense light, and as the foil is consumed the arc blows itself out, the whole operation lasting perhaps 1-100

of a second. The flash powder piled on the foil is consumed by the arc, and furnishes the additional light necessary for the exposure. The writer has never seen a baby afraid of this flash when fired in a well-lighted room, and has on several occasions made eight or ten exposures of a subject in a few minutes.

Another thing should be mentioned. A screen of some sort should be used between the subject and the flash. Either muslin or a piece of draft-man's tracing cloth can be used. Tracing cloth is probably the best, and a piece about 3 ft. square should be suspended about 18 in. in front of the flash. A string stretched between two thumb tacks on opposite sides of the room will serve to suspend the screen in the proper position. This serves two purposes: the subject is protected from the glare of the light and the light is suitably diffused.

The catch light seen in the eye in all portraits is merely a reflection of the light-source. Where this is small, as in an unscreened flash, the light in the eye appears as a small and brilliant point of light, so that most flash pictures can be identified as such by this alone.

Again, an unscreened flash will often affect the eye so severely that reflex action will close the eye, so that it will show as closed in the picture. With the screen in place the light is toned down, so that one never gets a picture with the eyes closed.

PERLEY H. FULLER.

AMATEUR OPPOSITION.

THE ever-increasing practice of photography by amateur camera users is, in some parts at least, having a marked effect on studio business.

The time was when "amateur opposition" would have been taken to mean the backyard operations of quarter-plate enthusiasts who fancied themselves as spare-time professionals, and mention of it would have gained but little attention. It would never have been considered as a menace to business. To-day the situation is different.

The latest slump in portraiture synchronised with the coal strike, and was thought to be a natural result of the strike and its subsequent bad trade, but while professional portraiture slumped, amateur photography was on the increase; and this, combined with certain other facts, make it appear quite reasonable that the snapshot was as much responsible for the professionals' bad time as the coal strike.

That the above assertion is not readily acceptable I know. For years the average professional has been in the habit of pooh-poohing the photography of amateurs. It has been beneath his notice, and therefore quite out of the question as possible opposition. But the dimensins to which "amateur finishing" and "d. and p." have grown have convinced many that snapshotting is not such an insignificant thing after all; and thus it comes about that studio after studio has taken up amateur finishing as a sideline, and some have gone further and made it their main line, with portraiture a poor second.

Now for some facts on which I base the assumption that amateurs' actirities are worth consideration. A studio in a mining district recently took up amateur finishing, and towards the end of the strike the portrait business was practically *non est*. The side line, however, was going so well that there was no fear at all of having to close down or reduce the staff. Which tends to show that the trade slump did not prevent those most affected from spending money on photography, and also that amateur work is replacing professional.

In the course of a year I see many thousands, or probably millions, of snapshots. By far the greater number are atrocious; some bad; some good; a few really fine, and an odd one in a thousand retouched: from which it will probably be assumed that they are not to be compared with professional work. But they all mean money, and are undeniably popular.

Of course, much of the vast amount of snapping has momentary value only. The prints do not advertise anyone or bring re-orders. But this does not apply to the good work on which the amount of money spent with many a dealer would be acceptable as total income in a small studio.

And amateur work does not stop at portraits. That some amount of outdoor work which might otherwise fall to professionals is done by amateurs can be readily understood, but on this count I do not think it is generally realised what an enormous number of wedding groups are snapped instead of being taken by professionals. And beyond this, the amateur has penetrated even into the holy of holies of commercial photography. I have seen and handled vest-pocket negatives of interiors, home and architectural, machinery and furniture. Not in any quantity, but in each case meaning money. I have even been asked to block out such negatives and get professional results, and firms who have allowed such photographs to be taken, instead of sending for a professional, seem to be totally ignorant of the fact that it is unreasonable to expect such results.

If professionals are not going to "feel the draught" they must take measures to protect and popularise professional work. Professional and amateur photography differ, and it is this difference that gives us clues to the situation. Professional portraiture is conventional; amateur portraiture is real. The former may have suited our Victorian ancestors and is essential to theatrical artists, but the latter has the stronger hold on the masses of to-day. Studio portraits, natural in comparison with the plant-pot studies of the past, need even more naturalising, and it is quite possible that gardens would pay better than glass houses for modern studios. The ancient fetish of retouching needs proselytising. Panchromatic or non-filter emulsions with careful lighting, exposure and development, will not only minimise retouching, but give as natural and more pleasing results than the average "snappist" ever gets.

The "snappist" and the amateur proper should be cultivated instead of being scared away or belittled. When they can go to a professional for advice, they don't then proceed to attempt the impossible with furniture and machinery. The commercial specialist, if he is short of work, should advertise not only that he is a commercial specialist, but that his work cannot be very well done by anyone else. Factory owners, many of whom carry vest-pocket cameras, do not all know this.

Last, but most important, are truth and quality. It may be a matter of opinion whether these things are known and appreciated by mankind in general, but it is a fact that they will tell in the end, and the deliberate operations of a true artist can be neither excelled nor equalled in any eyes by haphazard snapshotting.

Professional work of truth and quality is not likely to interfere with or be interfered with by the quite legitimate practice of amateur photography or professional amateur finishing, and our first-class professionals should be the last to experience what I have termed "feeling the draught." But, perhaps, I ought to point out that by quality work I do not mean merely chin-cutting and waist-shaving. Such and more wonderful things can be done with the film negatives of "folding-pocket" sizes.

THERMIT.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[The fifth annual volume of reports upon progress in the various branches of chemical manufacture, issued by the Society of Chemical Industry, includes, as did the preceding issues, a report on photographic materials and processes. This is again by Mr. R. E. Crowther, A.I.C., who (writing early in the present year) reviews the literature, published during the year 1920, representing original contributions to the technical improvement of processes of making negatives and positive prints, orthochromatics and colour photography, cinematography and photo-mechanical processes, and also the methods of research and measurement which are generally described as "sensitometry." Inasmuch as these reports are, so to speak, a series of annual stocktakings of what has been done during the twelve months preceding the issue of the volume, we have naturally wished to give them a place in our pages, since no other publication of the year so well reviews what has been done in reference to the current state of knowledge. As regards the references to original sources of publication, it should be explained that the contraction "J" denotes the fortnightly "Journal" of the Society of Chemical Industry in which are published abstracts of the chief papers relating to photography from the chemical standpoint.—EDS. "B.J."]

(*Concluded from page* 480.)

Process Work.

On behalf of the British Photographic Research Association, R. E. Slade and G. I. Higson[66] have published the results of an investigation on the influence of grain size on the gradation which an emulsion is capable of giving. They conclude that the ideal process emulsion should contain grains of one size only, a fact which, although not unknown amongst emulsion makers, does not appear to have been published hitherto. The production of such an emulsion and its coating on a very thin film should place a power in the hands of some of our scientific workers who are using photography in the investigation of problems relating to the constitution of matter. It is conceivable, for example, that the work on the isotopes of the elements, which F. W. Aston[67] is conducting at Cambridge, might be made quantitative in character and afford valuable experimental evidence of the proportion of the isotopes present in the more complex elements.

J. H. Christensen[68] protects the use of anti-swelling agents similar to those patented by A. J. Agnew, F. F. Renwick, and Ilford, Ltd. (Ann. Repts., 1919, 515), for assisting the selective tanning induced by development. Coupled with suitable developing bases in dilute solution, their action has made possible such a degree of tanning in the developed areas that the undeveloped portions may be washed away and the remaining image used in transfer work. The substitution of dyes for the pigments usually added to the carbon tissue resists used in photogravure has been patented by A. C. Braham,[69] who claims that a finer, sharper screen image is secured as the result of such substitution. The blistering which occurs when transferring the carbon print to its metal support is avoided, according to the patent granted to Rotophot A.-G. für graphische Industrie,[70] by an electrolytic matte etching of the support before transferring the print, and a device for mounting the etched intaglio cylinders used in "Rotogravure," so that centring is automatic, and neither rocking nor longitudinal shift results from wear, is the subject of a patent granted to J. P. Bland.[71] The present very satisfactory state of affairs in the application of photography in connection with catalogue illustration and advertising generally is to be attributed in no small measure to the attention which has been given to the design of half-tone screens. The arrangement of the rulings has a considerable bearing on the quality of the finished illustration, and the complexity of suitable designs is exemplified in the patent granted to W. R. B. Larsen.[72]

Cinematography and X-Ray Work.

The efficiency of projection screens used in cinematography has been investigated by C. W. Gamble,[73] who, with a fixed condition of illumination, obtained the judgment of an audience on an experimental picture. Although no attempts seem to have been made to measure the reflecting power at different angles, the results are of practical value and uphold Nutting's recommendation of a face-etched (sand-blasted) back-silvered mirror. Hydrofluoric acid etching was found markedly to restrict the angle of high efficiency. For the projection of subjects exhibiting strong contrasts the placing of a neutral tinted glass screen of low optical density in front of the projection lens is advised as tending to give better tonal quality in the picture. Up to the present celluloid has not been displaced to any great extent as a cinematograph film base—a fact which is somewhat remarkable, for in spite of its general suitability by virtue of its flexibility, transparency, and durability, the fire risk with celluloid is objectionably high. The substitution of other esters of cellulose is being slowly effected, and the experience gained during the war in the manufacture of non-inflammable dopes should assist in the production of an efficient substitute for celluloid, although the qualifying properties are not the same for dope as for cinematograph film. Ability to withstand a relatively high temperature without disintegration is demanded for the latter purpose if the undesirable complication of apparatus which is at present necessary for the interposition of stationary pictures is to be avoided. It is to be regretted that but little attention is apparently being given to this matter, the only communication of any note bearing thereon during the past year being the patent of W. J. Stevenson,[74] which protects the addition to cellulose acetate of triacetin and triphenyl phosphate in about equal parts and in amount varying between 10 and 20 per cent. Benzyl chloride and tetrachloroethane are stated to be suitable solvents.

The Royal Photographic Society is to be congratulated upon its foresight in assisting in the formation of a technical and scientific section. Amongst its various activities, this section has arranged special meetings for the discussion of the latest advances in photographic science. At a joint meeting of this section and the Röntgen Society many matters of import in radiography were discussed.[75] The Presidential address to the Royal Photographic Society by G. H. Rodman[76] also constitutes a communication of importance to those interested in radiography, dealing, as it did, very fully with the evolution of the X-ray tube. As far as sensitive materials suitable for radiography are concerned, there seems to have been little attention paid to the actual increase of the sensitiveness to X-rays, the majority of workers concerning themselves in perfecting the process in which an intensifying screen is placed in contact with the sensitive surface during exposure. The success so far attained in this direction is gratifying; indeed, the results which it has been possible to produce by the use of two intensifying screens—one on either side of a film coated on both sides with emulsion—lead one to anticipate with confidence that perfect radiographs of any part of the human body will be readily secured by instantaneous exposures. The appearance of this so-called "duplitised" film marks the beginning of an epoch which will reveal in the near future a

process in which the X-ray sensitiveness of the emulsion will be entirely ignored and the screen excitation be exclusively used to produce the latent image.

The factors which enter into the practice of radiography with intensifying screens are considered in a communication by R. Wilsey," from which it appears that the form of cassette in which the film is enclosed during the exposure has a considerable influence on the rendering of fine detail. It will be evident that the use of two intensifying screens will in some measure reduce the objectionable grain which frequently mars the detail when one screen only is employed, but a device has been protected by Siemens und Halske A.-G." which should practically eliminate such grain. A continuous metal screen is employed, and it is claimed that the characteristic radiation of the metal excited by the X-rays is most efficient in the formation of a latent image.

Sensitometry, etc.

Perhaps the outstanding event in this section during the year was the publication of the collected papers of Hurter and Driffield, the most important of which were communicated orignally to this Society. The value of the publication is materially enhanced by the inclusion of a very complete bibliography of work which has any bearing on the matter dealt with by Hurter and Driffield, and photographic workers throughout the world will appreciate the large amount of painstaking labour which W. B. Ferguson has expended in compiling the volume.

The question whether in sensitometric work the light intensity factor should be a constant and the time factor a variable, or *vice versâ*, has been but little discussed in the past, it having been generally assumed that the results obtained by either method were reliable. The work of H. J. Channon" makes it clear, however, that under certain conditions of low light intensity the time factor is relatively insignificant.

The intermittence error introduced when instruments of the sector wheel type are used has long been recognised, and various attempts have been made to design practical non-intermittent sensitometers. L. A. Jones" has described an apparatus of this type which gives results of precision: the measurements made with its aid indicate that both the speed and gamma of a plate are independent of the absolute exposure, not variable with it as is the case when intermittent exposures are investigated. A non-intermittent apparatus of a simpler design, in use in the laboratories of the British Photographic Research Association, has also been described by G. I. Higson.". Of the varying density scale sensitometers the Chapman-Jones "test plate" has been perhaps the most generally useful for approximate work hitherto available. A somewhat similar piece of apparatus has been put on the market by J. M. Eder, who, in describing its characteristics and the method of applying it in sensitometry, photometry, etc.," compares it with other apparatus much favoured by Continental experimenters. Lüppo-Cramer," in reviewing the instrument, points out that the "threshold value" for the determination of which sensitometers of this type are specially designed, is liable to be very misleading as an indication of the usefulness of a sensitive emulsion.

A contribution to the theory of tone reproduction has been made by L. A. Jones," who brings together all previous work on this subject and, after compiling a vocabulary of suitable terms and units, suggests a graphical method of solving the problems connected with the reproduction of tones by photographic processes. The question of the relationship of grain size to sensitiveness has been carefully investigated by T Svedberg," who, working with very thinly coated plates, shows that the curve obtained by plotting exposure against the number of grains made developable thereby is similar to the usual characteristic curve, and that the curve which results from plotting grain size against the number of grains made developable, is an exponential. All his results support the view that the larger grains are the more sensitive. It remains now to be settled whether the sensitiveness of the grain is a function of its size as such or whether the higher sensitiveness of the larger grains arises primarily, if not exclusively, from some other modification of the grain induced by treatment which simultaneously causes growth of the crystals. It seems probable, in view of the very recent introduction of exceedingly fast plates exhibiting low "graininess" which are prepared by a new ripening process, that grain size *ipso facto* and sensitiveness are not necessarily interdependent. Whilst dealing with the subject of grain, reference should be made to the important piece of research which has been conducted by L. A. Jones and N. Deisch" on the "graininess" of photographic deposits. The term "graininess" is applied to the characteristic which the practical photographer has hitherto referred to as "grain," and since much confusion has arisen in the past from the application of the latter term to both the original crystals in an emulsion and the aggregates or clumps of reduced silver in a developed image, it is high time that distinctive terms be adopted. Many factors which were reputed to influence graininess were examined quantitatively by means of novel and carefully standardised methods, and the results, which are of too varied a character to detail in a report of this nature, are of supreme interest to the "process" worker and the scientist who employs photography in work where images exhibiting maximum resolution are desirable.

The Hurter Memorial Lecture delivered before the Liverpool Section of this Society by F. F. Renwick (*vide* ') constitutes one of the most important items in the year's progress, not only on account of the fact that a new unifying theory of the latent image was advanced. In addition, an account of the novel experiments, the results of which support this theory, was presented, and a very full bibliography of work on the latent image bears testimony to the large amount of work which has been carried out in the pursuit of this elusive entity.

The above communication, like that of H. J. Channon," in which several more or less uncommon properties of the latent image are dealt with, cannot profitably be dissected for detailed discussion in this report, but their importance will be realised immediately they are consulted in the originals.

It may be noted with satisfaction that the experience in aerial surveying which was gained in the late war is likely to be turned to good account not only in mapping out inaccessible land areas but also in the charting of shoals and hidden reefs under the sea. A communication by W. T. Lee" deals especially with this latter work, and indicates that valuable information has already been secured.

Before concluding this report—which by reason of the manifold applications of photography in the arts and sciences must of necessity appear somewhat disconnected—reference should be made to the activities of the British Photographic Research Association, which appears, judging from the matter which has been published under its ægis,", ", ", to be getting to grips with the important theoretical problems connected with photography. The breadth of outlook indicated in the above communications inspires confidence that the Association will fully justify its existence, and augurs well for the future of the photographic industry in this country.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Specimen Frame Economy.

Frames for exhibiting specimens in showcases and windows may be improved, renewed and altered in size and shape in a very simple manner, and at a small cost by the use of common moulding used by builders for chair and picture rails, etc. Such moulding is not, of course, intended for picture framing, it having no rebate for the glass and picture; it is also of plain wood, but it is obtainable in many artistic patterns at 2d. or 3d. per foot. The plan is to make an overlay of this builder's moulding and to tack it to old existing and shabby frames by means of fine brads. The corners of the moulding frames are mitred in the usual way, and afterwards stained. A common form of frame for small specimens is the ½-in. oak shown in section in fig 1, the black por-

Fig. 1.

tions representing the frame, with glass and picture in position. Using wider moulding as an overlay (shown dotted in fig. 2), one

Fig. 2.

may, if desired, lessen the picture portion, *i.e.*, the visible portion, and thus broaden the frame considerably without altering the outside size (wall covering power) of the frame. I frequently use a 3-in. wide moulding on a ½-in. oak moulding with good results; much, however, depends upon the size of the original frame, it not being advisable in some cases to use an ornamental (beaded) overlay much, if any, wider than the original flat and narrow oak. If the frame is to be made larger without altering the picture area, a broad overlay is fitted as shown, in section, fig. 3. In

Fig. 3.

this case the overlay is laid flush with the inner side of the frame and made to overlap the outer edge. Shapes of frames may also be altered by suitably adjusting the overlay on the original frame. —L. T. W.

Rusty Plate Sheaths and Separators.

The metal plate-separators and the sheaths used in changing-boxes and magazines often become shabby and develop rust, the latter particles finding their way to sensitive surfaces and causing pinholes and spots. Metal used for such purposes should be kept very clean and free from rust, and it is a good plan to give it a coating of celluloid varnish, the latter, if clean, causing no ill-effects. The ordinary celluloid varnish of commerce may be used, or that made at home by cleaning the gelatine from a spoilt celluloid film and dissolving the latter in amyl acetate. Correct proportions for a really good varnish are 15 grs. of celluloid film or cuttings of the same, in 2 ozs. of amyl-acetate.—L.T.W.

FORTHCOMING EXHIBITIONS.

September 10 to October 8.—London Salon of Photography. Latest day for entries August 31. Particulars and entry form from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Latest date for entries August 26 (carrier), August 27 (hand). Particulars and entry forms from the Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 2 to 6.

Apparatus.—No. 20,750. Photographic apparatus. A. J. Elliott and H. B. Stringer.

Cameras.—No. 20,698 Photographic cameras. F. A. Ellis.

COMPLETE SPECIFICATIONS ACCEPTED.

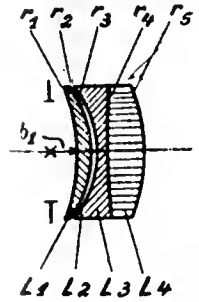
These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Triplet Anastigmat Lenses.—No. 158,902 (February 9, 1920). The invention relates to spherically, chromatically, and astigmatically corrected photographic lenses having the diaphragm in front, of the class comprising a collective meniscus and a cemented dispersive meniscus separated from the former by an air space having the shape of a collective meniscus, the cemented surface being collective and convex towards the incident light, and has for its object to produce specially favourable correction conditions, more particularly as regards the coma errors, in order to enable the objective to be used as an interchangeable element of a so-called "convertible" lens.

It has already been attempted in various ways to obtain the most favourable correction conditions in three-lens objectives with the diaphragm in front, and a collective meniscus next to the diaphragm, by making this meniscus uncemented, so that the air space situated between it and the cemented components could be utilised for correcting the errors. This was based on the assumption that it was desirable that the refractive index of the uncemented positive meniscus should be comparatively high—for instance, greater than the refractive index of the cemented single lens next to the air space on the other side thereof. Further investigation has, however, shown that the selection of such a comparatively high refractive index for the uncemented positive meniscus of the objective not only did not lead to the best possible correction conditions, but, on the contrary, precluded the possibility of satisfactory corrections.

According to the invention, a considerable improvement of the correction conditions is obtained by reducing the refractive index of the uncemented positive meniscus, for instance, by making this refractive index the same as that generally used for the



meniscus in the usual cemented three-lens systems of the well-known kind, the refractive index of the positive meniscus being smaller than that of the adjoining negative component.

The invention thus comprises a photographic lens of the above-mentioned class having a positive uncemented meniscus on the side towards the diaphragm, the refractive index of which is smaller than that of the next bi-concave lens.

An objective having these characteristics can be obtained which is distinguished by specially accurate correction of the coma with very small intermediate errors. Moreover, the zonal aberration, even when the relative aperture is very great, can be kept very small; there is also the possibility of a very thorough correction of the chromatic aberration.

Finally, a substantial manufacturing advantage, as well as an increase in the value in use of the new object-glass, results from

the fact that, owing to the reduction of the refractive index of the positive meniscus, the latter can be made of easily manufactured durable borosilicate crown glass, which is highly transparent.

The drawing illustrates diagrammatically a lens constructed according to the invention. L_1 indicates an uncemented collective meniscus, L_2 an air space in the form of a collective meniscus, L_3 is a dispersive lens cemented to a collective lens L_4.

In the following table of elements r_1 r_2—indicate the radii of curvature of the various surfaces from left to right in the drawing, d_1, d_2—indicate the thicknesses of the components L_1, L_2—, and n_D and nG^1 indicate the refractive indices for the D and G^1 lines of the spectrum respectively. b_1 is the distance between the plane of the diaphragm and the centre of the first surface. The dimensions are appropriate for an equivalent focal length of 100 units.

$$b_1 = -1.80$$

$r_1 = -15.00$	$d_1 = +1.17$
$r_2 = -9.00$	$d_2 = +0.33$
$r_3 = -8.38$	$d_3 = +0.73$
$r_4 = +63.33$	$d_4 = +3.00$
$r_5 = -14.42$	

L_1 — $n_D = 1.51220$, $nG^1 = 1.52221$
L_2 — (air)
L_3 — $n_D = 1.52320$, $nG^1 = 1.53083$
L_4 — $n_D = 1.62140$, $nG^1 = 1.63503$

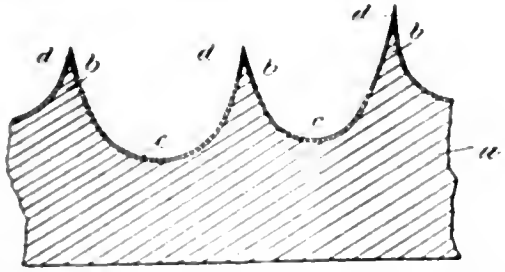
Diameter of full aperture = 8.00.

—Optische Anstalt C. P. Goerz Aktiengesellschaft, 45/46, Rheinstrasse, Friedenau, Berlin.

Lantern Screens.—No. 161,545 (April 10, 1920). According to the invention, dark coatings for the tips of the reflecting surface are formed. This results in that the projecting points or tips which are most liable to reflect the light (in projection in daylight) will be no longer able to reflect the same, but, on the contrary, absorb it, whilst the recesses, which are provided with a reflecting coating for the reflection of the projected image, remain effective.

Alternatively, the projecting screen itself may be made of a material which, on account of its colour or other reasons, is able to absorb the daylight, and in such a case a coating of the projecting tips with light-reflecting material need not be resorted to.

In the drawing, a is that part of the screen in which the surface is so shaped or roughened that projecting points to tips



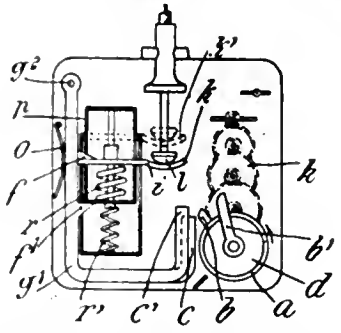
b and recesses c are formed. These tips, according to the invention, are provided with a dark coating d, whilst the recesses c have a covering of some highly light-reflecting material.—John Emlington-Darling, 5, Culmbacherstrasse, Wilmersdorf, Berlin, Germany, assignee of Carl Oskar Roehrich, 4, Augsburger Strasse, Charlottenburg, Berlin.

Self-Portrait Shutter Releases.—No. 141,331 (April 8, 1919). The invention relates to apparatus for operating photographic shutters in which the shutter trigger is actuated after a predetermined interval, and, after a further adjustable interval, is again actuated.

A uniformly rotating axis is provided with devices for successively operating, with an adjustable interval, spring-actuated members which respectively and in succession actuate and release the shutter trigger.

According to one design shown in the drawing, a drum a is driven by a clockwork movement provided with a barrel and also with a train of wheels, the rotation of which is regulated by a fly. This drum imparts a retarded rotary movement to a disc d, which carries two fingers a and b^1. The first finger b, by coming into contact with the upturned end c of an L-shaped lever causes the lever to turn on its pivot, and consequently releases a projection f on the lever from contact with a plate i provided with a support k for the release button l. The plate i and support k, under the action of a spring r, then rise to the position k^1, carrying along therewith the release button l, which movement produces the opening of the shutter.

The second finger b^1, which is adjustable at will relatively to the finger b, acts in its turn on the end c^1 of a second L-shaped lever g^1, causing the lever to turn on its pivot g^2 and liberate a projection f^1 on the lever g^1 from a casing p containing the spring r. The casing then descends under the action of a spring r^1 and that of the release button (and of the shutter), and



this second movement produces the closing of the shutter. The finger b^1 being adjustable with respect to the finger b, the interval between the two positions of fingers determines the duration of the time exposure. A small, flat spring o serves to maintain the two ends c and c^1 of the L-shaped levers in their normal position.—Société Anonyme pour l'Exploitation d' Inventions I.S.A., 53, Rue du Stand, Geneva, assignees of Jacques Bogopolsky, 53, Rue du Stand, Geneva.

Lantern Screens.—No. 166,893 (July 6, 1920). The invention relates to screens on which cinematograph pictures can be seen in daylight. It consists of a semi-opaque sheet or sheets of glass, celluloid, or other material, so roughened or indented upon one of its surfaces as to present protuberances, ridges, or nodules, which will cast shadows or will themselves be partly in shade when the rays of the sun are thrown obliquely or transversely upon them.

Thus a sheet of glass which is smooth on one side may be provided with parallel V-corrugations on the other, crossing one another at right angles so as to leave pyramidal nodules, formed by casting, moulding, or cutting the surface. The smooth face (or back) of the glass may be covered with white or light toned paper or fabric or coated with aluminium or other paint in order to render it semi-opaque, while white or light-tinted paint may be applied to the indented surface. Alternatively to the use of such covering and painting the glass may be of the kind known as opal or semi-opaque. When the daylight or sunlight falls upon such a screen at any angle except a right angle (which in practice would never be a probable angle), the high light will be broken up into lower lights or shadows by the evenly distributed nodules which are spread in close formation over the whole surface. Any picture projected from a lantern upon such a screen will be rendered visible because of its rays falling upon the innumerable shaded spots, which become illuminated by the picture instead of by the daylight.

In another form of the invention, the face of the screen may be ribbed in one direction only, and when this form is used, the daylight or sunlight may be caused to impinge upon it transversely on all occasions by providing means by which the screen can be adjusted to the most favourable angle. For instance, such a screen may be caused to revolve in its own plane upon an axis at right angles to itself, and for this purpose it may be mounted in a frame or upon a holder provided with the necessary gear by which the ribs on the screen will always be placed transverse to the rays of the sun, and such rays may be either direct or suitably deflected thereon by mirrors.—John Hill Coverdale, 128, Braybrook Road, Hastings, and Frederick Chetwynd Jessett, Bush Lane House, London, E.C.

Sensitive Collodion.—No. 166,063 (September 16, 1920). The patentee has discovered that collodion in which the solvent employed consists entirely or mainly of methyl alcohol enables him to introduce organic iron salts in the coating mixture or emulsion, whereby light-sensitive films which have distinctive properties are obtained. Moreover, such coating mixtures or emulsions have

other advantages, amongst which may be named that the mixtures flow more readily and easily than the ordinary collodion coating mixtures, and are far less liable to accumulate dust or specks than are water-soluble coating mixtures.

A collodion coating mixture or emulsion is prepared by making up collodion with methyl alcohol as the solvent, to which may, however, be added, either at the time of preparing the collodion or subsequently a proportion of some other solvent, for example, ethyl alcohol. The latter has the property of lessening the porosity and increasing the density and clearness of the collodion film, which can be controlled and regulated by the amount of ethyl alcohol in the coating mixture. The most useful results are obtained when the proportion of ethyl alcohol to methyl alcohol in the finished coating mixture is as 1:3 or 1:4. A trifling proportion, not exceeding 2 or 3 per cent. of water will, on the other hand, increase the porosity of the collodion film, and can be added to the collodion mixture, if desired.

A solution of the organic iron salt is made and added to the collodion. The salt preferred is ferric ammonium citrate, and the preferred solvent is methyl alcohol. If the salt, as in the case of ferric ammonium citrate, is not completely soluble in the methyl alcohol, then only the soluble portion is decanted and used in the mixture.

The mixture so prepared produces a light-sensitive film when coated on glass plates or other material, but in order to increase its sensitiveness the plates may be bathed in an alcoholic solution of other metallic salts, such as silver, gold, platinum or palladium salts, either singly or in combination. Some salts suitable for the purpose are silver nitrate, gold chloride, platinum chloride, or palladium chloride. It is preferred, however, in place of bathing the plates, to add the salts for obtaining increased light-sensitiveness to the mixture itself, preferably dissolving them in ethyl alcohol. The ethyl alcohol so used may be made to serve the double purpose of dissolving the added salt and of producing the desired degree of density of the collodion film, as referred to above.

A typical light-sensitive collodion coating mixture or emulsion would be composed as follows:—

6 per cent. celloidine dissolved in methyl alcohol, 2 parts by vol.
Ferric ammonium citrate saturated solution in methyl alcohol, 1 part by vol.
2 per cent. silver nitrate in ethyl alcohol (industrial spirits), 1 part by vol.

The main claim is: Light-sensitive coating mixtures or emulsions for photographic purposes, of collodion containing an organic iron salt, preferably ferric ammonium citrate, in which the solvent employed to produce the collodion consists wholly or mainly of methyl alcohol.—Julius Rheinberg, 57, Holborn Viaduct, London, E.C.1.

The following complete specifications are open to public inspection before acceptance:—

STEREOSCOPY.—No. 167,179 Optical devices adapted to obtain stereoscopic images. A. J. Toupillier.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

R. L. (PRISM DESIGN).—No. 399,184. Philosophical instruments, scientific instruments, and apparatus for useful purposes; instruments and apparatus for teaching. Ross, Ltd., Optical Works, 3, North Side, Clapham Common, London, S.W.4, manufacturers.

STAR IN CIRCLE (DESIGN).—No. 394,057. Chemicals for photographic purposes and synthetic dyes, all being goods included in Class 1. Gregory and Co., Bycars Laboratories, Hamil Road, Burslem, Stoke-on-Trent, manufacturing chemists.

AIRCO (DESIGN).—No. 398,894. Photographic cameras. The Aircraft Manufacturing Co., Ltd., 25 and 27, Old Queen Street, Westminster, London, S.W.1, and Edgware Road, The Hyde, Hendon, London, N.W.9, manufacturers.

SPLENDOL.—No. 398,351. Chemical photographic developers. Cutler Hill Colour and Chemical Co., Ashton Road East, Failsworth, Manchester, aniline dye and photographic chemical manufacturers.

SKEG-CARDS.—No. 400,579. Photographs on cards. Herbert John Jackson, 25, Ford Street, Coventry, photographer.

MONAL.—No. 399,892. Chemical substances used in photography. The Portsmouth Photo Co., Ltd., Pompey Works, 8, Arundel Street, Portsmouth, photographic manufacturers.

APTUS (DESIGN).—No. 402,531. All goods included in Class 1. Moore and Co., 101 and 103, Dale Street, Liverpool, photographic apparatus manufacturers.

PONTOPRINT.—No. 401,856. Pictures, prints, engravings and photogravures. G. and G. Ponton, 128, Renfield Street, Glasgow, die-sinkers and engravers.

PACTOL.—No. 402,193. Adhesives (mucilage paste, gum, labelling solution), prepared as articles of stationery. United Chemical Corporation, Ltd., 39, Victoria Street, Westminster, London, S.W.1, manufacturing chemists.

FORTEX.—No. 403,211. Philosophical instruments, scientific instruments and photographic apparatus, all being included in Class 8, but not including spectacle lenses and not including any goods of a like kind to spectacle lenses. Fred Walter Baxter, 17, Chryssell Road, Brixton, London, S.W.9, manufacturer of photographic apparatus.

WELLINGTON (CHILD DESIGN).—No. 412,402. Photographic plates, films and chemicals. Wellington and Ward, Shenley Road, Borcham Wood, Elstree, Hertfordshire, manufacturers.

DISTAR.—No. 362,971. Optical instruments. The firm trading as Carl Zeiss, 2, Carl Zeiss Strasse, Jena, Germany, manufacturers of optical and philosophical instruments.

New Materials.

Eclipse Ultra-rapid Plates. Made by the Imperial Dry Plate Co., Ltd., Cricklewood, London, N.W.2.

FOR many years the Imperial "Flashlight" plate has held an enviable position as regards speed and the other qualities which are demanded in a dry-plate emulsion of high quality, its great sensitiveness satisfying those who require a plate of extreme rapidity. With the demand for greater and still greater rapidity on the part of photographers of sporting events under often unfavourable conditions of lighting, the Imperial Company have perfected a plate of still higher sensitiveness, which they have recently issued as the "Eclipse." The plates sent for our trial are marked 650 H. & D., a number which indicates a speed more than 50 per cent. greater than that of the "Flashlight." While the H. & D. is not a full measure of the sensitiveness of a plate, comparative tests against a "Flashlight" show the difference between the two to be fairly indicated by this numerical rating. The many photographers who in the past have pledged their faith to "Imperial Flashlights" under conditions requiring the maximum light-action on a plate can hardly ask for a more emphatic testimony to the speed quality of the new introduction.

Moreover, with pyro-soda or metol-hydroquinone, the plates develop quickly and allow of any ordinary degree of vigour being readily obtained. An ultra-fast emulsion in some cases does not fix as quickly as one of medium speed, but we observe no sluggishness as regards fixing with the "Eclipse" plates. The makers, however, recommend that plates should remain at least seven minutes in a fixing bath containing 6½ ozs. of hypo in 20 ozs. of water. It is likewise deserving of notice that plates of this extreme rapidity call for more than the usual care in respect to exposure when loading and developing. Apart from other factors, fogging is a question of a certain time of exposure to even a "safe" light. The makers have to use part of that time in the manufacture and examination of the plates: the user needs to expose the plates as little as he can to what remains. A deep ruby safelight, such as the Imperial No. 4, is recommended. With these precautions taken, there will be no difficulty in obtaining negatives of fine gradation

and complete freedom from veil under the conditions of minimum exposure, such as frequently prevail in focal-plane and Press photography.

LUMIÈRE DESENSITISER.—Mr. Thomas K. Grant, 89, Great Russell Street, London, W.C.1, sends us a sample tube of the Lumière "Desensibilisateur" for the desensitising of Autochrome and ordinary plates for development in a bright yellow light. The contents of the tube are mixed with 35 ozs. of water to make the working bath, in which Autochrome plates are immersed for 30 seconds; ordinary plates for one minute.

RADIO-LUX ANTI-HALATION PLATES. — MM. R. Guilleminot. Boespflug & Cie. send us a sample of the anti-halation plate issued by them as "Radio-Lux," and described some months ago in these columns by M. L. P. Clerc. The special feature of the plate is a coating of brown manganese peroxide between the glass and the emulsion film. This supplies an intensely effective obstacle to the production of halation and, moreover, in the "Radio-Lux" plate is produced in such a degree of transparency that the plate can be developed as readily (by transmitted light) as one unprovided with backing. In an acid fixing bath the peroxide-layer is immediately decolourised and removed. Further particulars of the plates may be obtained from the London representative of MM. Guilleminot, M. Jules de Gottal, 7, Cecil Mansions, Marios Road, London, S.W.17.

PROFESSIONAL PASSE-PARTOUTS.—It has always been a matter of some surprise to us that professional photographers should make such comparatively little use of passe-partout framing, not only for the neat and artistic display of specimens in the window, but also for supply to customers. As regards the former, it is a very common sight to see soiled prints in a window, and also those which, as soon as the sun strikes the window, begin to curl up at the corners, presenting a very unsightly appearance. It would seem that many shirk the trouble of mounting specimens passe-partout fashion. Those who do so surely cannot have made the acquaintance of the ready-made passe partouts which are a specialty of Messrs. W. Butcher & Sons, Camera House, Farringdon Avenue, London, E.C.4. These passe-partout frames, supplied under the name of "Kwick-Mount," are available in a series of different patterns for prints from c. de v. to whole-plate size, at prices which run from 1s. to 3s. each. The mounted print has simply to be laid in contact with the glass and the binding flaps brought over it and secured by a gummed strip. These passe-partouts allow of prints being replaced by others, and their extremely neat and pleasing design recommend them both for window displays and supply to customers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

THURSDAY, AUGUST 25.

Hammersmith (Hampshire House) P.S. Debate—"Straight v. Faked Photography." Leaders: P. Chatterton and A. Hanson.
North Middlesex P.S. "Enlarged Negatives." W. Robinson.

SATURDAY, AUGUST 27.

Bradford Phot. Soc. Excursion to Hawksworth.
City of London and Cripplegate P.S. Outing to Hampton Court.
Kinning Park Co-op. Soc. Trades' Holiday Outing.

CROYDON CAMERA CLUB.

Recently the informal session has been living from hand-to-mouth, which seems to agree with its varied composition. Last week Mr. E. A. Salt filled a gap with a demonstration on "Palladiotype," hardly of a grandiose nature, as only modest half-plate prints were handled, but the metal palladium, like platinum, he explained, costs much good money. Also, he preferred carting about small dishes to large.

Introduced during the war, when platinum was almost unobtainable, Palladiotype, he said, has since been so improved and tuned up as to constitute practically a new product. Although the solutions employed are different, it may be regarded as a variant of Platinotype, being worked in exactly the same way.

After an outline of the theory of the process, he said that Palladiotypes are sensitised to give a beautiful warm black (some might consider it a brown) on matt papers, supplied in many grades. The natural surface of the paper is retained unchanged with the image right on top, and not embedded in gelatine or starch. The "vellum" (semi matt) papers give a warmer tone. Palladiotype is a cold-bath process, and affords a robust initial image enabling correct exposure to be judged after a trial or two. Development is best effected as soon after printing as feasible, and the prints do not deteriorate if left in the clearing baths long beyond the regulation time.

Very useful in the case of flat negatives, or when additional sparkle is required, is the addition of a small quantity of potass bichromate to the developer. Unless the salt be added in excess no injury to the quality of a Palladiotype picture occurs. So minute a dose as half a grain in 20 ozs. of developer gives slightly added contrast; it is not advisable to go beyond 4 or 5 grains to the pint. Printing must be carried further according to the amount of oxidant added.

In the discussion, Mr. J. M. Sellors, as an old Platinotype worker, paid tribute to the newer process, in so far as it resembled its prototype, which excelled in the beautiful gradation it gave in the lighter tones. Mr. A. F. Catharine preferred Palladiotype; the term "brown-black" might mean anything, but the particular colour or tone secured was just right and could not be bettered. Thanks to the absence of the usual colloids, the maximum of brilliancy was secured on a perfectly matt paper. Mr. H. P. C. Harpur said he had known palladium confused with peptonised milk and music halls. To his cost he had recently realised it was a very precious metal indeed. For direct work he always used Platinotype, as it lasted for ever and ever. Touching, too, upon the infinite, Mr. V. Jobling suggested coating on asbestos, for the last speaker's exclusive use.

Commercial & Legal Intelligence.

LEGAL NOTICE.—Notice is given, pursuant to Section 242 (5) of the Companies Consolidation Act, 1908, that the name of Park's Press Photographic Agency, Limited, has been struck off the register of Joint Stock Companies, and the company is dissolved.

EASTMAN KODAK COMPANY.—The directors have declared the following extra dividends:—2½ per cent. upon the common stock, payable on October 1, to stockholders of record on August 31; 5 per cent. upon the common stock, payable on November 1, to stockholders of record on September 30.

The ordinary quarterly dividends of 2½ per cent. upon the outstanding common stock, and of 1½ per cent. upon the outstanding preferred stock will be paid as usual on October 1 to stockholders of record on August 31.

CANVASSING PHOTO-COLOURING FRAUDS.—At the Canterbury Police Court last week, Ellen Elizabeth Vincent was charged with obtaining 2s. from Eva E. Hobbs on July 12 with intent to defraud and cheat.

Chief Constable Carlton stated that prisoner called at Mrs. Hobbs' residence at 37, New Town Street, at 11.30 a.m. on July 12, and asked if she had photographs which wanted colouring, saying that she did miniatures for 1s. 6d. and cabinets for 2s. 6d. Mrs. Hobbs gave prisoner four photographs, and, upon the woman asking for a deposit, 2s. for which a receipt was given. Prisoner said the photographs would be finished in a week, and also added that she was opening a business in St. George's Street on the following Monday—a statement since proved to be untrue. On July 25 Mrs. Hobbs went to 7, Blackfriars Street, Canterbury, the address on the receipt, and found that prisoner had left a week previously. The photographs, with several others, were recovered from that address. Prisoner was apprehended at Branksome, Dorset, and upon being received into custody by

P.S. Richardson, who charged her with the offence, the woman said, "That's quite right. I also had the photographs." At Canterbury, when charged, prisoner replied, "I certainly did not take the money under those conditions—to defraud."

Eva Elizabeth Hobbs and P.S. Richardson bore out this statement in evidence, the former adding that prisoner showed her a specimen photograph and asked for details as to the colour of the hair, eyes, etc

Prisoner, who pleaded "Not Guilty," said she fully intended getting an office and settling in Canterbury to colour photographs, as she had always done As money she had been expecting from home did not come, she could not complete the photographs in the time. She could not remain at her lodgings as she could not pay her landlady. She had intended going to Bournemouth—her home—but remained near by until Wednesday last. In about a week's time the photographs could be finished. She had a list of her various customers in Canterbury, with the amounts they had paid She had fully intended to complete the photographs, even had they been a little late. A remand was ordered.

When prisoner appeared again she was charged with two further offences on July 8 (*a*) of obtaining the sum of 2s. 6d. from Mildred Thatcher, of 40, Artillery Street, Canterbury; and (*b*) of obtaining the sum of 3s. from Emily Streeting, of 23, Artillery Street, Canterbury. No evidence was offered in a charge of obtaining the sum of 1s. 6d. from Violet Blissett, of 41, Artillery Street, Canterbury. The evidence given by the complainants showed that the circumstances were similar to those of the above case.

P.S. Richardson, in evidence, said that altogether he recovered 75 photographs from 7, Blackfriars Street, Canterbury. Prisoner, when charged, said she had nothing to add to her statement.

The Chief Constable informed the Bench that prisoner was bound over in the name of Nellie Simmonds at Bournemouth in 1917 for embezzlement, and was sentenced to three months' hard labour at Guildford Petty Sessions in February last for stealing money as bailiff. There was a further warrant out against her in the name of Nellie Lee for obtaining 5s. by a trick from Lilian Beatrice Houghton, at Eastbourne, which prisoner desired should be taken into consideration. There were ten other complaints of a similar nature from Eastbourne, which prisoner admitted were with regard to photographs. She was 36 years of age.

The Chairman said that having taken into consideration the Easthourne case, the sentence would be two months' hard labour in each of the three cases heard, the sentences to run concurrently

News and Notes.

Mr. R. Hume, to whom we recently sent the reply to a question, is asked to send a stamped envelope bearing his address, since that enclosed with his query has been returned by the postal autherities

Mr. William Bell, of Criterion, Ltd., is open to accept engagements for lectures and demonstrations in Lancashire from the following dates:—Monday, October 16, to Saturday, January 21, 1922, inclusive.

Mr. F. W. Speaight, we are informed, delivered a lecture to members of the Press on Tuesday evening last, describing his plans for the improvement of the Horse Guards' Parade, which, with certain modifications, have just been approved by Parliament.

A Rescuer's Camera Stolen.—Before jumping into the sea fully dressed to save a child from drowning at Southend a photographer left his camera in charge of a man on the Western Esplanade. After restoring the child to its mother, the rescuer found that the man had vanished with the camera.

Mr. William Field died suddenly from heart failure on the 6th instant while on holiday. He was for over 50 years in the service of the Autotyne Company, appreciated and esteemed by its successive principals and by his fellow servants. Many photographers who knew him will regret his decease.

Professional Field Cameras.—Messrs. Sands, Hunter & Co., 37, Bedford Street, Strand, London, W.C.2, have just issued a 32-page list almost exclusively occupied by specifications of the many field cameras for outdoor professional use of sizes from half-plate to 15 x 12. These include many examples of the lighter conical models as well as the heavier substantial patterns still largely in favour by many professionals. A copy of the list will be sent on application.

Mr. W. B. Ferguson, M.A., K.C., whose health, we are very sorry to hear, has lately been a matter of some concern, has this week left London for Baden, Aargau, Switzerland, where he expects to remain for several months, and may not return to England until the spring. While he is ordered to rest, immediate photographic friends are asked to note that his address in Baden is Hotel Bären. We join with many others in wishing Mr. Ferguson a complete restoration to health.

A French Chemical Congress.—The Société de Chimie Industrielle is holding an important congress of applied chemistry in Paris from October 9 to 12 next. The proceedings will be divided among numerous sections, including one relating to photographic manufacture. A series of visits to works is being arranged, and also an exhibition representing all branches of industrial chemistry, in which the majority of French firms will take part. Further information is obtainable from 49, Rue des Mathurins, Paris.

A New Poison Bottle Bill.—Last week there was introduced a Bill in the House of Commons proposing that every chemist when selling poisons must with every bottle state on the label the antidote to the poison, so that in case of any mistake a swift remedy may be applied. The penalty for failure to comply is put at £5. One criticism raised is that the vendor should be allowed to state the antidote in writing instead of print on the label. Another is that if such precautionary statement is made, it may prevent people from calling in a doctor in case of accidental poisoning. The introducer of the Bill is General Surtees, M.P., for Gateshead.

D. 50.—In response to a large request for this new developer in form ready for use, the Cooper Laboratory, Watford, have decided to supply the ingredients for the No. 2 solution in tablet form. Four tablets provide the chemicals necessary for use with 1 oz. of D. 50. Cartons of 8 and 16 tablets are being issued to retail at 6d. and 9d. each respectively, and the tablets will also be put up in boxes of 100 to retail at 3s. 6d. per box. A sample packet containing a small bottle of the D.50 concentrated solution, together with a tablet providing the solid chemicals for the No. 2 solution, is also being issued, price 9d. from any photographic dealer, or post free on application to the Cooper Laboratory, Watford.

A New Form of Educational Film is now being shown to English audiences, the pictures illustrating how the eye sees, how the ear hears, how the heart and lungs work, etc. The pictures are a development of the moving picture cartoon, and owe their origin to a Mr. G. R. Bray, of Chicago. The writer of the "films column" in the "Star," describing the new pictures, says that the heart is first photographed from a dark cardboard background, then a transparent plate is superimposed, showing the chambers of the heart, and the two are photographed together. After that several other plates, showing changes in the chambers, are superimposed. In fact, one background is often used with 20 or 30 transparent plates.

The Camera in Fiction.—All writers of fiction have not so good a grasp of photography as they might have, and many "howlers" have been recorded. Mr. E. V. Lucas, however, seems to be fully alive to modern methods, for in his "Listener's Lure" he makes one of his characters (Adelaide Fielding) write to a friend:—"I wish you would send me a photograph of yourself. . . It is quite useless to tell me that you never go to a photographer. That excuse is dead and buried. Photographers come to us now. I am as certain that Edith (another character figuring in the story) has a camera as that I have not." And the page from which this extract is made is headed: "To everyone a camera or two." Such free advertisements of photography are welcome.

Story of a Good Photograph.—An excellent piece of propaganda, which recently has been undertaken by the British Photographic Manufacturers' Association, is the circulation of a small booklet, entitled "The Story of a Good Photograph" which is being extensively advertised in the lay Press. The booklet, which is written by Mr. Arthur C. Brookes, very simply puts forward the ways in which anyone may take up photography, and usefully emphasises the simplicity of photography as a hobby as a result of the improvements in apparatus and materials. The booklet includes

advertisements by British manufacturers. Although it was intended that the booklet should be distributed solely as a result of advertisements in the Press, with the object of attracting those who at present do not number photography among their hobbies, applications from dealers for copies of the booklet have been so numerous that the B.P.M.A. has agreed to supply dealers with a limited number of copies for free distribution strictly to non-photographers at the nominal charges of 5s. for 50 copies; 10s. per 100 copies, in each case post free. Application for the booklet should be made to Sicilian House, Southampton Row, London, W.C.1, enclosing remittance, since it is not possible for the Association to open up a number of small accounts.

REMOVING STAINS, ETC., AND BLACK LETTERING FROM CANVAS BLINDS.—The following paragraph, which we clip from "Work," contains some information which may be of service to those of our readers who have their studios or shop fronts fitted with canvas blinds:—To remove mildew and stains from canvas, cut 1 lb. of good yellow soap into shavings and boil into a stiff paste with soft (preferably rain) water. Apply this to the stain by rubbing vigorously, and sprinkle with finely powdered potass carbonate. Spread the fabric on a grass plat and allow to remain there for twenty-four hours. When dry spray the canvas with rainwater and wash, when the stain will have disappeared. The black lettering on shop blinds is usually effected by stencilling or painting with an enamel or paint. If this is the case, it will be easily removed by vigorously sponging with any of the following solvents: Chloroform, carbon tetrachloride, ether, acetone, aniline, or nitrobenzene. Aniline is to be preferred since loss due to evaporation is least with this solvent. Should the lettering be printed with a carbon ink, however, it will be necessary to bleach the canvas. Therefore, if any of the above solvents fail to give satisfaction, proceed as follows: Boil the fabric for three hours in a solution containing 37 gr. of potassium cyanide (a powerful poison) per 1¾ pt. of water, wash and warm in a closed vessel containing a solution of 81½ gr. of chloride of lime per 1¾ pt. of water. As soon as the vessel is full the solution is allowed to cool and drawn off carbonic acid gas (carbon dioxide) is passed in. This operation of warming in the bleaching solution and treating with gas is pursued until all the lettering has been removed. In some cases a slight yellow tinge is retained by the fabric owing to traces of iron impurities in the bleaching agent. To remove this coloration the canvas is drawn through a bath of oxalic acid (about 70 gr. per gallon of water), washed with water and dried.

EARLY PHOTOGRAPHY BY MAGNESIUM LIGHT.

To the Editors.

Gentlemen,—To borrow a phrase from the letter of your correspondent, "P. R. S.," in the issue of July 8, p. 406, "I do not propose, however, to write a history of flashlight work," merely to detail some facts, which may perhaps put a different complexion on the subject from that outlined by your correspondent.

H. Larkin (Eng. Pat. 2,786, 1865) patented the use of magnesium powder, which was supplied to a flame in a continuous stream from a funnel. The inventor points out that it is convenient to mix it with sand, ground flint or glass in the ratio of 1 magnesium to 3 sand, etc., and the use of ribbon or wire, burnt in a lamp, is also claimed. F. W. Hart ("Phot. News," 1864, 209) refers to the use of magnesium ribbon, and Johnson and Matthey announced that on April 1, 1865, the price would be reduced to one-half. Up to this time it was, I believe, from 100 to 150 shillings per pound.

At a meeting of the British Association, Section B, W. White ("Phot. News," 1865, 437) gives a very good sketch of the uses of magnesium generally and of the work of Piazzi Smyth, and says: "Magnesium filings.—It is a question whether magnesium in filings has met with due attention. It would not be difficult to deliver a stream of the metal, as sand from an hour-glass, into a jet of gas or other flame, and thus maintain a light with a certainty equal to that obtained by wire and clockwork."

At a meeting of the South London Photographic Society, November 9, 1865, reported in "Phot. News," 1865, 550, "Mr. J. T. Taylor ignited a portion of a powder consisting of antimony, magnesium, sulphur and potassium nitrate, which gave a momentary flash of very actinic light, with which, he stated, instantaneous photographs could be obtained." And this was not in the days of the fast gelatine plate. E. T. de Banzie (Eng. Pat. 5,462, 1881) patented a lantern for burning magnesium or other "heliopyre" compound.

In an editorial article ("B. J.," 1887, 530) reference is made to the Gaedicke and Miethe patent. Traill Taylor's experiment is recalled, and it is stated that an editorial article on the subject appeared in the following year. Appended to the above patent specification is the following note: ("We never like, where it can be avoided, to throw cold water upon a patent; but it is probable that the patentees in this case had never read an article in our issue of May 24, 1867, 'Photography by a Flash,' and from which we here make a brief extract: 'Mr. Skaife finds in magnesium powder, when mixed with other pyrotechnic compounds, the means of obtaining a flash of light of the desired intensity and brevity. At the meeting of the South London Society in November, 1865, we ignited a powder composed of magnesium, chlorate of potash and sulphur, by which we had been able a few evenings previously to obtain a sharp image of a print while it was being slowly moved.' This, we imagine, settles the fate of the foregoing patent.—EDS.")

G. A. Kenyon ("B. J.," 1883, 61) used magnesium ribbon burning in oxygen, and stated also that magnesium powder and chlorate could be used.

Eder Handbuch, 1905, 1, 1., 331, which deals with the history of photography, says: "Photography with magnesium powder in the form of 'flashlight,' as it was then called, *first obtained development by the work of J. Gaedicke and A. Miethe in Berlin, and soon thereafter the whole world was busy with the same*, since the explosive mixtures of magnesium powder (magnesium, chlorate of potash and antimony, and later other mixtures, see below) recommended by the same actually burnt as quick as a flash and gave instantaneous pictures of portraits and groups, etc., on gelatine plates. About the same time Meydenbauer became busy with the same subject. *After Gaedicke and Miethe had given the new impetus to magnesium flashlight photography*, the excellent properties of pure magnesium powder, blown through a flame, were learnt. T. N. Armstrong drew attention shortly after the publication of the Gaedicke-Miethe flash powder to the fact that pure magnesium powder blown through a flame gives an intense light ('B. J.,' 1887, 77). After which a large number of different 'flash powders' and magnesium flash lamps were given, which (as well as the experiments with aluminium flash light) are described in another volume of this work."

Thus is history made! The italics above are mine, and the actual truth is that the price of magnesium was dropped to one-fifth. See "Phot. News," 1887, 193.

Now for some other facts. As recorded above, White had suggested the use of pure magnesium twelve years prior to the Gaedicke-Miethe "epochmachenden" discovery. W. H. Harrison ("Phot. News," 1885, December 15; "B. J.," 1886, 81) described dropping magnesium powder, mixed with sand from a funnel, thus following Larkin. See above.

The Gaedicke-Miethe German patent is 42,966, April 27, 1887, for a mixture of magnesium 30 parts, potassium chlorate 60 parts, antimony sulphide 10 parts, with or without the addition of 10 per cent. of sodium, calcium, strontium, lithium or barium salts to give colour to the flame, and a lantern to burn the same in. Their English patent (7,035, May 13, 1887) patented magnesium 6 parts, potassium chlorate 12 parts, and potassium "prussiate" 1 part, or Mg, 12 parts, $KClO_3$ 24 parts, and amorphous phosphorus 1 part, with the other earthy salts, about 10 per cent. of the latter being claimed. In their book, "Praktische Anleitung zum Photographieren bei Magnesium Licht" (Berlin, 1887, reviewed "Phot. News," 1887, 350) the German patent and Traill Taylor are followed. H. W. Vogel, in his usual letter to the "Phot. News," 1887, 340, said the results were first shown in Berlin by Gaedicke

on March 11, but not explained till April 15, and stated that chlorate and nitrate were used.

A. Hemsley, U.S. Pat. 407,351, 1889, application date May 4, 1888, claims the same thing and the use of the earthy salts "to produce orthochromatic effects similar to that produced by a specially prepared plate with an interposed colour screen."

T. N. Armstrong's paper was read before the Glasgow Photographic Association (reported "B. J.," 1887, 777; "Phot. News," 1887, 773). Armstrong described Piffard's and Traill Taylor's experiments, and, referring to the German proposal, says that such compounds are not at all desirable on account of their explosive character, the sulphurous fumes and the antimony oxide, the latter being poisonous. His own plan was to use a chemical wash bottle with two tubes. He writes: "I consider the blowing through a gas flame of this powder to be a great stride in the right direction in the class of work we are considering to-night, especially as it solves the difficulty of being able to throw the light from any desired angle, which is easily done by a common movable gas bracket with universal joints." See also "B. J.," 1889 38.

Dr. H. G. Piffard's experiments were made before the Society of Amateur Photographers of New York ("Phot. News," 1887, 697, 720). He first used gunpowder in the ratio of 3 to 1 magnesium (cf. A. H. Elliott, "B. J. Almanac," 1888, 450), and later adopted nitro-cellulose, sprinkling this with twice its weight of magnesium (cf. F. C. Beach "B. J. Almanac," 1888, 439; "B. J.,' 1886, 114). W. J. Harrison ("B. J.," 1887, 790), in an article entitled "Magnesio-Cotton Light," refers to Piffard's work, and appends the following postscript: "I find that a mixture of lycopodium powder and magnesium triturated in a mortar and blown from a tube through a gas flame yields a very brilliant and momentary flash."

At a meeting of the North London Photographic Society of January 3, 1888, reported in "B. J.," 1888, p. 2, reference was made to Armstrong's work, and in "B. J. Almanac" this note is summarised as follows:—

"Here is a description of one of an excellent nature introduced by Mr. W. Bishop early in the year. A metallic spirit lamp, having a flat top, is fitted with two wicks, one in front of the other. Immediately behind this is a reservoir containing magnesium in powder into which dips a glass tube, the other end being carried up through the cork and bent towards the flames of the spirit lamp. A second short tube is passed through the cork, its outer end being connected with the rubber tube of a pneumatic ball. On giving this ball a quick, sharp squeeze a small quantity of the powder is suddenly ejected against the flame, this being attended by a dazzling flash. This is capable of being repeated as long as any powder remains in the reservoir.

"The lamp of Mr. H. M. Hastings is very simple. A plain glass tube has an ordinary 'thistle' as a terminus at one end (as readily procurable from every dealer in glass tubes), and a single turn or loop is formed in the tube in the middle by softening it in a spirit lamp and giving it a loop turn, leaving the main body of the tube in a straight length as before. Now, if the tube be charged with powder by pouring it in at the wide end, it stands to reason that none of it will get lost or spilt, as it will all be arrested at the turn of the tube, and when the puff of air from the pneumatic ball is subsequently sent through the tube, it performs its function so thoroughly as to eject the powder without leaving a trace of it behind. Of course, either end of the glass tube may be directed towards the flame; the larger one seems advantageous, as it may aid in spreading out the charge on the principle of the now extinct blunderbuss.

"On one end of the tube is sprung a piece of rubber tubing terminating in a pneumatic ball, and on the other end is 'shipped,' by means of a spiral wire, a split brass tube, a spring clip, or any other convenient mechanical appliance, a tube of wire gauze about three inches long and half an inch in diameter packed with asbestos. This tube, which constitutes the lamp, is dipped in a bottle of alcohol and thus becomes charged. It now only remains to light the spirit lamp, and press the ball when the flash follows.

"Mr. A. James has devised a lamp which, judging especially from the results obtained, appears to be eminently successful. An ordinary Argand gas burner is employed, the glass chimney being removed, and a stream of magnesium is ejected into the flame from the orifice of a tube in the middle and below the level of those through which the gas is emitted.

"On lines somewhat analogous, although differing in a material degree, is a lamp, the invention of Professor Redwood. In this there are two circular wicks (Argand fashion) rising from the top of a spirit lamp, and both are inclined towards each other, so that the two flames combine. To each is the magnesium powder supplied through a tube below, and both tubes are supplied from a small reservoir of the powder, over which, when charged, a lid fits tightly. The powder is ejected in the usual way, viz., by means of a pneumatic ball and rubber pipe, connected with a brass tube which is fixed in the reservoir. This angular arrangement of the burners ensures perfect combustion, and also distributes the flame over a larger area. The lantern in which it is enclosed is of japanned tin, bright on the inside, and bent in a cylindrical form. There is no glass in front, but a sheet of white blotting paper is fixed in front and held by a suitable clip, and when the powder is ignited it becomes powerfully illuminated by a soft light, like that from a white, luminous cloud. This prevents that glare which is so oppressive to the eyes of the sitter, softens the shadows, and harmonises with the conditions under which daylight portraits are taken, as the area of illuminated paper in front of the lantern is considerable, or about two feet square."

F. W. Hart and W. Bishop applied on January 1, 1888, for Eng. Pat. 356, and H. T. Redwood on January 13 for Eng. Pat. 582, 1888, and this lamp was placed on the market by Marion & Co., though the patent was abandoned.

A. James ("B. J.," 1889, 62) claims priority for the idea of blowing magnesium through a flame (ignorant, probably, of White's 1865 suggestion), and obtained Eng. Pat. 2,730, February 23, 1888, for a lamp, and Eng. Pat. 6,917 for trapping and removing the smoke (cf. "B. J.," 1888, 66, 69). A. L. Henderson ("B. J.," 1899, 60, 94; "B. J. Almanac," 1907, 659) suggested incorporating magnesium in cylindrical pencils of celluloid so that different lengths could be cut off and allowed to burn slowly, which was the first suggestion for a so-called "time-light cartridge," subsequently patented by others.

We now come to the Schirm patents; the German is 45,532, of April 4, 1888, and Eng. Pat. 5,974, April 21, 1888. Therefore we may justly claim that he was anticipated by Englishmen, and cannot be said to have "invented the plan of burning pure magnesium powder (not a mixture) by blowing it through a flame."

I am afraid that this letter has expanded beyond the usual limits, but it is, I think, as well to place some of the facts, at any rate, in due sequence.—Yours faithfully, E. J. WALL.

Wollaston, Mass.

D 50 AND METOL POISONING.

To the Editors.

Gentlemen,—I have been interested in the notices of the new developer D 50, as I have been using it since Mr. Gear's article upon it in the "B.J." I have found it an excellent developer, especially for portrait negatives, and I think that the claim that it enables a shorter exposure to be given is well founded, and its staying power is certainly remarkable. It will develop a surprising number of prints or negatives. I had some little difficulty in persuading my principal assistant to use it regularly at first, but he seems to prefer it now. He has found, however, that in developing bromide prints it has a tendency to softness, and has sometimes complained of difficulty in getting a sufficiently brilliant print from a soft negative; but he has found a remedy for that defect by adding to it a small proportion of the old hydroquinone and caustic soda developer, as used a good many years ago. This is a fine developer for negatives and prints of line subjects, especially for lantern slides of plans and such like. He found the combination of the two produced excellent results, and a few days ago he tried a rather daring experiment. Having some enlargements to make from thin negatives, he developed first with caustic soda and hydroquinone, and got a harsh, soot and white wash image, then transferred it to a dish of D 50 until the half-tones appeared. The resulting prints toned to an excellent sepia.

A similar plan was tried with plates that had been exposed too long, and the results were very good.

But one of the virtues of D 50 is that it contains no metol, and

this should be good news for those who suffer from metol poisoning. The same assistant some months ago was troubled with sores on his right hand, which were, I believe, caused by metol, especially as we had been using the Universal developer recommended in an article in your columns, containing hydroquinone, metol, and caustic soda. I have never suffered from metol poisoning myself, although I have used it ever since it was first introduced, so that I cannot be sure that my assistant was afflicted with it. His doctor had never seen a case either, and the only treatment suggested was poulticing. This seemed merely to relieve the irritation, which was not great, but it did not seem to effect any cure. But as soon as he began to use D 50, and rarely touched metol, the sores seemed to become less inflamed and began to heal. The cure was hastened by using Cooks' antiseptic soap, and the sores are now quite healed up, and the pits they caused gradually filling.

I would recommend anyone who suffers from any skin trouble to try this soap. There are two qualities—3 per cent., a green tablet, and 1 per cent., a white one. The 3 per cent. is the most effectual. Some people suffer in summer from small blisters on the back of the hands, causing terrible itching and irritation, but this soap will cure it almost at once, and if a little of the soap, diluted with glycerine and water, is rubbed over the hands every morning, none of the blisters will appear.

I would certainly recommend all who suffer from metol poisoning to use D 50 and the antiseptic soap. I need not say that I have not the slightest interest in either product, but I believe metol poisoning is so terrible to those who suffer from it that it is the duty of anyone who knows of a remedy to publish it.

BI-FOCAL

A CONTRAST RATING FOR BROMIDE PAPERS.

To the Editors.

Gentlemen,—The average printer of to-day has one very great advantage compared with the printer of 20 years ago. In 99 cases out of 100 he uses bromide or gaslight paper—or, more likely, one or more of those papers which have not yet had a really good name assigned to them, but are midway between bromide and gaslight for speed. He has, therefore, a very wide choice of surface, speed and contrast, and can suit his paper to almost any type of negative he may be called upon to print. Herein, however, lies one of the pitfalls of modern printing, as the young and inexperienced printer is often at a loss to know which make or grade of paper to use, with which to get the very best result from any particular negative, and is often tempted to continue the use of one grade of paper indefinitely, regardless of those negatives which differ from normal, and which the best of operators will occasionally favour us with. Again different batches of the same make of paper sometimes vary considerably as to contrast, though I am glad to say this does not happen so frequently now as during the war-time period, when manufacturers' difficulties were many.

What is wanted is a standardised method of marking batches of paper in the same way that plate speeds are standardised under the H. & D. system. The standardisation of contrast in papers, however, is a simpler process than the working out of plate speeds. All that has to be done is to find by trial the exposure needed to give the faintest indication of an image from a clear slit, and also that needed to give the deepest black that the paper will give. These can be called respectively the minimum exposure and the maximum exposure. Now the ratio $\frac{\text{min: exp:}}{\text{max: exp:}}$ indicates the contrast ratio of the paper. If, for convenience, this is multiplied by 1,000, we get a series of numbers which will show at a glance the contrast value of any batch of paper. For example, the ratio $\frac{\text{min: exp:}}{\text{max: exp:}}$ for a fairly soft paper might be 2/80. This, multiplied by 1,000, gives 25. On the other hand, a vigorous gaslight paper might give the result 3/20. This, when converted into our contrast number, would be 150.

One advantage of this system would be that a photographer who was particularly pleased with the results given on a particular batch of paper could state when giving his next order that he wanted so many gross "Vitura" paper, contrast 50. The manufacturers would then, no doubt, comply with this request, and the printer could then carry on, with the knowledge that the re-orders would stand every chance of being up to the standard of the previous prints sent out.—Yours faithfully, HUGH TAYLOR.

51, St. Anne's Road, Manchester.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad. Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. L.—As the photograph was ordered and you supplied it at a price, the person who gave you the order is the owner of the copyright. This is one of the most elementary facts of copyright law. We suggest that it would be to your advantage to have the little book, "Photograph Copyright" issued by our publishers, price 1s. 3d. post free.

RECEPTIONIST.—We think you may take it that the proof photograph was made to the order of the deceased sitter, and in those circumstances the copyright became his. While it may be uncertain as to what became of the copyright on the decease of your present customer's father, you will certainly be safe in assuming that you are not infringing anybody's copyright in supplying the prints.

A. REX.—We think that if you suffer severely from metol poisoning the substitution of potass carbonate for soda carbonate will not be of advantage. However, if this were the case it is not possible to tell, simply from the formula, what is the equivalent quantity of potass carbonate which should be used. The best thing you can do is to choose one or other of the formulæ which have been published for the use of metol with potass carbonate.

J. H.—The formula given by Mr. Jones in the "B.J." of February 25, 1921, was corrected by him in the issue of March 4 as follows:—

Metol	¼ lb.
Hydroquinone	½ lb.
Soda sulphite	4 lbs.
Caustic soda	1 lb.
Water to	2 gals.

D. N.—As you received the order, the copyright is the property of the Corporation, and in the absence of any special agreement in writing to the contrary you have no right to issue postcards from the negatives. On the other hand, the negative is your property, for use according to the directions of the Corporation. It is difficult to say what is a reasonable price for it if the Corporation wish to buy it, but in view of the fact that a copy negative can be so easily made, most photographers, in such circumstances, are ready to accept a price of from 10s. 6d. to £1 1s.

H. S.—So far as relates to the reproduction of the critical definition, *e.g.*, fine lines contained in an original in the copy negative, it is chiefly a question of using an anastigmat lens at a moderate aperture, say, not more than *f*/16, and of focal-length of considerable length compared with the plate. For a half-plate 10 inches would be about a correct length. The longer focus enables the more central part of the field only to be used. At the same time an anastigmat is not an absolute necessity. In many process studios one sees R.R. lenses in use, but always of long focus relatively to the plate.

S. AND C.—(1) The best form of lamp for enlarging from dense negatives is a small arc; a good pattern is the Westminster enclosed arc, which is made primarily for projection work. (2) It is better to have a separate lamp for each retouching desk, a 16 c.p. metallic filament bulb is quite strong enough. A piece of thin very pale blue paper should be placed below the negative

to diffuse the light. (3) The Barkay reflector is an excellent appliance, and practically doubles the light falling on the sitter. A 3,000 c.p. half-watt fitted with this reflector would meet all your requirements. As a side-light only you would probably be able to do without the reflector.

O. B.—We think that unless you have some experience in printing on metal and etching it will not be very easy for you to produce goods of the quality shown in the samples. These labels are made by one or other of the customary processes used in making photo-etched blocks, that is to say, sensitising the metal with fish-glue enamel and bichromate and etching the printed image with, usually, perchloride of iron. Printing may be done from a positive in order to obtain the imagine in intaglio. Full instructions appeared in the "B.J." of October 29, 1915. There is, or was, a firm specialising in the making of these labels, namely, Jee Metal Label Co., 79, Peckham Rye, London, S.E.15.

J. A.—The distances 74 yds. and 111 yds. (= 2,660 and 4.000 inches) are very long ones for getting an image of 1½ inches size of a man, say, 69 inches in height, and require focal-lengths, respectively, of 56 and 85 inches. We imagine that Mr. Vining had in mind a shorter length than 74 yds., and also probably enlargement of the largest image obtainable with a lens of the fixed-focus telephoto type which could be used at a reasonable camera extension. With a Ross "Telecentric" of 17 inches focus, requiring an extension of about 9 inches, the image would, therefore, be about one-third the size, say ½ inch, requiring enlargement 3 diameters. With an "Adon" you could get a greater focal-length, but at the cost of a smaller aperture. For this long focus work a reflex camera is the only type.

K. L.—So far as copyright is concerned, the only person who can take any objection to an enlargement being made is the sitter, that is to say, if he or she gave an order in the ordinary course. From this standpoint, neither you nor your employer have any right to have an enlargement made. Suppose that you obtain the sitter's permission, then it is rather doubtful whether you have the right, as an employee, to have an enlargement made. So far as we know, the law is by no means clear in the matter, but our view is that you have not such a right. The use of the negative would be a matter for arrangement between you and the proprietor. We think employers are very short-sighted in refusing to grant reasonable facilities for the obtaining of specimens, and have many times made representations on this matter in the "B.J."

Ben.—Convenient materials for the home manufacture of weights are the various sheet metals, of which the most suitable is lead, and particularly 9-lb. lead—that is metal which weighs 9 lbs. per square foot. A piece 4 ins. square thus weighs 1 lb. and 1 in. square 1 oz. This 9-lb. lead serves very well for the making of odd weights required in particular formulæ. For example, an 800-grain weight is made by calculating the area required—namely, 1 5-6 square inches. A piece measuring 1 in. by 1 5-6th will thus give as near as possible the exact weight. For smaller weights sheet lead weighing 1 lb. per square foot is a convenient material, the thinner gauges of lead being readily folded to reduce their bulk, or they can be cut into long strips, rolled up compactly, and the value of the weight and the purpose for which it is to be used marked with paint.

M. S.—(1) If the club consents to a free sitting, then, without any doubt at all, you have the right to dispose of the photographs in any way you like, and permit other people to do the same. That would apply to the group as a whole, and to individual persons, providing, of course, in each case that neither the club as a body nor individual members gave you any order to take the photograph, that is to say, such an order that they would be liable for payment. If you give them enlarged prints of any kind, then, of course, you confirm the free sitting arrangement, but such gift is not really necessary. (2) We are sorry we know nothing about royalties on sales of copies. We have never heard of clubs demanding to be remunerated in this way. (3) If you copy the photograph of anyone of note, it is more likely than not that it is the copyright of the other photographer. We imagine that it is this possibility of infringement from which your customer very naturally wishes to be protected.

A. M.—There is not very much choice among 12 x 10 cameras, but in this size a light model is advisable. You could not do better than a Watson's "Acme," expensive, but no doubt you could get one, or a similar one, second-hand. As regards lens, it will obviously be necessary to have one of fairly large aperture, say, not less than *f*/6, and of focal-length about 15 inches. Really we are of opinion that it is better to use a smaller size of camera for such indoor subjects, as you can then get the required depth with a lens of larger aperture, and if you must have 12 x 10 prints they can easily be obtained by enlargement of a very moderate degree. We think there is no very useful purpose in having the camera larger than whole-plate. The only type of camera for rapid sports subjects is the folding focal-plane, of the type formerly sold by Goerz, and now obtainable of British make from Messrs. Peeling and Van Neck, 4-6, Holborn Circus, London, E.C.1. A camera of this type is also made by Houghtons and Thornton-Pickard.

Focal-Plane Shutter.—(1) Does the exposure vary in equal proportion to width of slit, *i.e.*, does 1-in. slit give double exposure of ½-in. slit, and so on? (2) Which has most power of arresting motion, a wide slit at high tension or narrow slit at low tension, provided the exposure is the same? (3) I have lost my table of exposures, but I think I can recollect the top line. Providing this is correct, will the rest of the table be correct enough for practical purposes :—

Width of slit.	Tension. 1	5	10
1½ ins. ..	1/25 sec. ...	1/35 sec. ...	1/50 sec.
1¼ ,, ...	1/30 ,, ...	1/40 ,, ...	1/60 ,,
1 ,, ...	1/35 ,, ...	1/50 ,, ...	1/70 ,,
¾ ,, ...	1/50 ,, ...	1/75 ,, ...	1/100 ,,
½ ,, ...	1/70 ,, ...	1/100 ,, ...	1/140 ,,
¼ ,, ...	1/140 ,, ...	1/200 ,, ...	1/280 ,,
⅛ ,, ...	1/280 ,, ...	1/400 ,, ...	1/560 ,,
1/16 ,, ...	1/560 ,, ...	1/800 ,, ...	1/1120 ,,

R. F.

(1) Yes, the exposure is proportional to the width of the slit. (2) So far as arresting movement there is no appreciable difference, but on the ground of getting a greater degree of light action on the plate, a wide slit at high tension is better than a narrow slit at low tension (equivalent exposures), especially when a lens of large relative aperture (F. No.) is employed. (3) Presuming the first line of your table is correct the exposures calculated in accordance with the width of the slit will be also correct; that is to say, the exposures for a ½-in. slit would be one-third those of a 1½-in. slit.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3199. Vol. LXVIII. FRIDAY, AUGUST 26, 1921. Price Fourpence.

Contents.

SUMMARY.

Dr. B. T. J. Glover, in a contributed article on page 503, returns to the subject of factorial development of bromide paper, and, in the course of an introduction, examines the ability of a system of developing "by the look of the prints" to give the most correct rendering of the negative.

We owe to the courtesy of Dr. C. E. K. Mees the translation of a paper by a Russian physicist, M. G. V. Potapenko, on the theory and technique of light-filters, the first instalment of which appears on page 507.

The various uses which can be made of mirrors in portraiture and commercial photography are the subject of notes on page 505.

The professional or skilled amateur photographer, who is often inclined to underrate the capabilities of a folding film camera, is advised to make himself acquainted with the working of any given instrument of this type, particularly in regard to the points mentioned in a leading article on page 502.

At the Croydon Camera Club last week Mr. Vivian Jobling described how to make corrugated metal grooving, such as that required for draining racks. (P. 512.)

Mr. John A. Tennant sends us references to further information respecting the pioneer work in cinematography of the American inventor, C. F. Jenkins. (P. 514.)

Messrs. Kodak, Ltd., will no doubt cause surprise to many by their announcement that they have discontinued the manufacture of glass dry-plates, having converted this department of their Harrow works to the production of Eastman Portrait Film. (P. 514.)

Firelight portraits are always an attractive feature in showcases. A note on one respect in which they are often defective will be found on page 501.

The making of a copy-negative from a customer's original, which is sent for reproduction, should be the regular rule before any treatment whatever in the way of renovation is attempted. (P. 502.)

Processes of making projection screens of a kind suited for the exhibition of cinema pictures are the subjects of recent patent specifications. (P. 511.)

The styles of enlargement which can be offered to customers at prices which preclude comparison with those of the cheap enlargements widely offered, are the subject of a paragraph on page 501.

For those moderate degrees of intensification, which portrait negatives generally require, the single solution mercury-iodide intensifier can hardly be improved upon. (P. 502.)

A simple means of attaching the back end of the focussing cloth, so that it is prevented from flapping about in the wind, has recently been suggested in an American contemporary. (P. 502.)

EX CATHEDRA.

Firelight Portraits. The firelight effect in portrait work is perhaps regarded as meretricious by many high-class photographers, but to the more modest practitioner it affords a welcome variety in his specimens and is always attractive to the general public. The introduction of the half-watt lamp has rendered the production of these pictures very simple, and we advise all who use this illuminant to arrange one or more of their lamps for it. All that is needed is to arrange for the light to come down as low as the bars of an ordinary grate, to provide a screen or framework to give the effect of the jamb of a fireplace, and to screen the lamp itself from the lens. A common error in this class of work is failure to illuminate the figure so that its outline is not altogether lost. In a genuine firelight effect it is always possible to see the whole figure, but in many photographs we can only discern the face and hands and a few high-lights nearest the lamp. This can be avoided by using reflectors so placed as to catch the light from the lamp and throw it upon the figure in a natural way. Under-exposure and over-development are to be avoided, the use of a dilute developer being the best way to avoid hardness.

* * *

Saleable Enlargements. It should be the aim of every portraitist who is doing a good class of trade to endeavour to produce enlargements of distinctive character, which cannot be placed in competition with cheap work of the sort offered by canvassers and postcard studios. Much of this latter work is of fair technical quality, and the general public cannot see a great deal of difference between the picture offered at a guinea and that at five or ten times as much. It is therefore necessary for the good-class man to make his pictures look worth the money he asks for them. There are many ways in which this can be done. In the first place, genuine carbon or platinum prints with a guarantee of permanence may be pushed; or an actual life-sized head in toned bromide, framed close up in a heavy dark moulding, may prove attractive. Another attractive style is the oil-finished bromide in monochrome or colour, which gives the effect of a crayon drawing upon a tinted base. These framed in polished oak are very attractive, and the oil coating tends to preserve the image from fading. In all cases it is desirable to quote a price which includes the frame, otherwise the effect may be ruined by an injudicious choice on the part of the customer. There are also the opportunities for the supply of enlargements of comparatively moderate size, produced in a lighter and also less expensive style in platinum, carbon, or bromide. An enlargement from quite a small negative, or from part of a larger one, permits of very pleasing effects being obtained in the passe-partout style of mounting, and enables articles to be offered at a price suited to the most modest purse. More might still be made of these styles.

A Copying Note. The copying of old photographs is an important branch of our art, but it does not always receive the care which is due to it. As a rule, the originals are irreplaceable, and their loss or injury is a very serious matter to their owners. As a rule, no attempt should be made to clean or improve them until a negative has been made, this being in the nature of an insurance against accidents. If it then be thought desirable the surface may be washed with clean water, or bread crumbs may be used. There is, however, always a risk of removing the spotting or working up, and it is not easy to replace this upon a faded print. It is also likely, if the print is upon albumenised paper, that the surface will be cracked. The application of any liquid will wash the dirt into the cracks and make the appearance worse instead of better. The surface of a daguerreotype should never be touched by an inexperienced person, the only permissible cleaning being by means of a bellows to remove loose dust or fluff. Much trouble may be avoided by having a fixed storage place, preferably a safe, for customers' originals. These have a very annoying way of getting mislaid either before or after copying, and the photographer's reputation is not enhanced if this happens.

* * *

The Focussing Cloth. We cull from an American contemporary a useful idea for making a focussing cloth which is particularly effective in windy weather. The cloth, which must be of ample size, is fixed round the lens or front part of the camera in the usual way, and is, in addition, slit down the back so that the two ends may be brought over the shoulders and fastened round the photographer's neck with one of the snap fasteners commonly used upon ladies' garments. This effectually excludes light, and is a great help when focussing with lenses of small aperture. Such a cloth need not be heavy or bulky if thin mackintosh be used instead of the heavy velvet or cloth commonly used. Another advantage is found in the fact that such cloths are waterproof and will protect the camera during a heavy shower without becoming sodden. The material known as "single proof gossamer" is very suitable, as it is very thin and has one side dull, so that it is as non-reflecting as an ordinary cloth. It will also serve as a cape for the photographer during a shower, while the camera is safely stowed in its case. The only precaution necessary is to keep grease or oil of any kind from rendering it sticky and destroying the rubber coating.

* * *

Single Solution Intensifiers. The principal disadvantage of the most popular methods of intensification, such as mercuric chloride, followed by ammonia or ferrous oxalate, or the chromium formula of Welborne Piper, is that there is little control over the amount by which the light-resisting power of the image is decreased. It is true that by modifying the strength of the solutions and the proportions of the ingredients, more or less density can be obtained, but it remains that in any case, the intensification is done in what we may call one jump, and that the extent of this cannot be judged until the process is complete. For this reason it is much to be preferred to use a single solution with which the strengthening can be watched and stopped directly the desired stage is reached. In this category, the most useful agents are found in mercuric iodide and uranium. The latter, however, does not find much favour with professional workers, on account of its colour, which renders retouching difficult, and its fugitive character. Mercuric iodide is free from these objections, and has also the advantage that a trace of hypo in the film is not detrimental. By dilution the rapidity of its action can be controlled, and if the negative appear to be a little too dense, a short immersion in a weak bath will reduce it to the desired degree.

USING FILM CAMERAS.

An idea, common to many skilled photographers, both professional and amateur, is that cameras designed for the exclusive use of films are more or less of the nature of toys and quite unsuitable for serious work. While it must be allowed that the absence of many of the adjustments found in well-made ordinary cameras imposes certain limits upon the class of subjects which can be attempted, the simplicity and convenience of the film camera renders its use practicable where a more perfect instrument could not readily be brought into action.

To obtain the best results which any camera is capable of yielding, it is necessary to understand its working powers and limitations. A Brownie camera will give a much better percentage of successes to a skilled hand than it will to a careless "snapper," and this applies in a higher degree to such cameras as are fitted with rising and cross fronts, rapid lenses in carefully-speeded shutters, and focussing scales.

The absence of the focussing screen is the greatest trouble to the erstwhile stand camera worker, and many disappointments result from the operator not being upon good terms with his finder and focussing scale, which he must train himself to use in its place. Before attempting to use a camera of the Kodak type it is a good plan to remove the back and to fit a piece of ground glass so that it rests upon the two metal rollers over which the film passes. Having focussed the image upon this and noted the amount of subject included, a comparison should be made with the finder image, so as to ascertain whether the two are identical, and also to find out what allowance is necessary for the accurate centreing of the subject when working at close quarters. Then it is necessary to note the effect of the rising front. When this latter is used, the lens is de-centred upon the plate while the finder is not affected, a point to be observed being the amount of sky, if any, which appears upon the ground glass when the top of a building touches the top edge of the finder. This should be done with the camera in both vertical and horizontal positions. The depth of definition at various apertures and distances may be ascertained by calculation, but the majority of photographers will probably find it easier to do so by observation of the image upon the ground glass. This is, moreover, less costly than gaining the same knowledge by spoiling film.

Exposure is an all-important point. The stand camera worker is likely to fall into error in the opposite direction to that made by the ordinary snap shotter, that is to say, he is likely to refrain from working in a light with which it is possible to get fairly good results. Here, the exposure meter is a useful guide. Those who do not already possess a meter will find the Watkins Snipe meter, which costs only eighteenpence, quite effective, and simpler to use than the ordinary meters.

The correct judging of distance, especially at close quarters, is somewhat difficult to the beginner in hand camera work, and nothing but practice will enable this to be done with a reasonable degree of certainty. Here, the ground glass screen will be found very useful, as the pointer may be adjusted to the distance at which an object is supposed to be situated and the result

checked upon the ground glass. It is also a good plan to pace the distances until the eye is sufficiently trained to estimate them correctly.

When these preliminaries have been gone through the operator may test his skill by actual exposures, taking careful notes of the distances and exposures and checking the results by their aid for future guidance. The procedure we have indicated may appear somewhat tedious, but those who have the patience to carry it through will find themselves amply repaid.

It must be remembered that the usefulness of a film camera is greatly extended by using it upon a tripod, or even upon a clip, which may be affixed to a rail, tree, or chairback, in cases where a hand exposure is not possible, or where great depth of definition is desirable, and stopping down becomes necessary. Subjects which would normally require the use of a swing-back need not be passed by, as it is quite easy to correct a considerable amount of convergence of the perpendicular lines by tilting the negative and the bromide paper during the process of enlarging. Although rarely fitted to film cameras, a direct vision finder is an extremely useful adjunct. It allows of exposures being made from the eye level, which is often the only position possible when working in a crowd or over a high parapet. That such finders are almost exclusively used by Press photographers is sufficient evidence of their usefulness.

Where a dark room is available, it is more convenient and quicker to use a trough or deep dish with a roller to keep the film under the solution as it is drawn through, than to use a tank. This practice also eliminates the risk of bubbles adhering to the film.

Care should be taken to avoid over-development, for small pictures are easily spoiled by loss of detail in the high-lights. If there are one or two under-exposed subjects in a film, there is always a tendency to prolong the development to the detriment of the others, while as a matter of fact even the under-exposed sections would yield better prints if developed for the same time as if correctly exposed.

We have not referred to film packs, as these are usually fitted to cameras which are also adapted for use with plates, but in the case of some of the Premo cameras, which are constructed for film work only, the procedure of testing, and so forth, as recommended for roll film work, will, of course, be applicable.

THE CASE FOR FACTORIAL DEVELOPMENT OF BROMIDE PAPER.

THERE are many photographers who have read what has been written during the last twelve months in reference to the factorial method of developing bromide paper who can see no justification for the employment of a more or less mechanical system of producing prints. It appears to be fairly generally thought that as the picture can be so plainly seen during the development of the print it must, therefore, surely be a most simple matter to develop until the print has the appearance desired and stop development at that moment by removal from the developer and fixation in "hypo." This opinion, namely, that the visibility of the prints' progress during development renders precise guiding rules unnecessary, appears to be that of Dr. Luppo-Cramer, who wrote recently in "Photographische Rundschau" on the subject of factorial development, and referred to its employment in the development of "positive" images, of which bromide prints are examples.

In the course of this paper the author will deal with this matter under the following headings:—

(*a*) The failure of development by inspection, except in the hands of photographers of considerable experience, and the reasons which contribute to this failure.

(*b*) The exposure and development properties of bromide paper upon which a scheme of work by rule can be based.

(*c*) The choice of the factorial system of development in preference to other schemes as a complete and reliable guide to *both* exposure *and* development.

The Failure of Development by Inspection.

By the expression "development by inspection" is meant the procedure advised by all text-books and employed by practically every photographer who produces prints upon bromide paper. It involves the making of a series of trial exposures and the development thereof until one of the trial images yields an appearance considered desirable in the finished print, the repetition of the exposure which yielded the correct trial slip image when exposing the final print, and the development of the final print so exposed until once again the desired appearance of the picture is yielded. Development is then checked, and the print is fixed. As a sort of hint that development needs to be carried out fully, it is usually advised that it should be carried on until it appears to stop.

Let it be understood that by "beginners" are meant all those photographers who are in the very early stages of their career as bromide printers or those who have been printing on bromide paper without success. They are a very numerous class. By "expert" is meant any photographer who can produce a bromide print of the most perfect quality that the negative will yield.

Let us watch a beginner at work (as I have done), and note his procedure. A trial exposure is made, let us suppose, in a perfectly correct fashion, several exposures being included upon the same piece of paper, each successive strip being given twice the exposure of the one before it. Let us assume the very best condition for success, namely, that in the choice of the trial exposures one of them is absolutely correct, and that on each side of this correctly exposed strip there are under-exposed and over-exposed strips respectively. The trial strip so exposed is placed in the developer and the image makes its appearance. It is a universal rule in development that the most exposed image commences development first and develops most quickly. It is here that every beginner makes a fundamental mistake. *The beginner deliberately attempts to make one of the over-exposed trial images look right by removing the trial strip from the developer and plunging it into the fixing solution before the image grows too dark.* The image upon the finished trial strip chosen for imitation in the final print is therefore necessarily *over-exposed and underdeveloped*, and the repetition of that exposure in the case of the final print again necessitates under-development of the final print in order to prevent it also from becoming too dark.

Now let us inquire (as I have done on many occasions) into the reasoning on the part of the beginner which leads to this procedure in spite of the text-book warning that development should be allowed to proceed until action apparently stops. In answer to a question as to why the trial strip was removed from the developer, the reply is invariably "because if I did not do so it would become far too dark, and would be

spoiled." Instead of condemning this deduction as foolish, let us trace the line of thought which leads to it. Exposure makes no visible change in the printing paper. The beginner may know that there is a latent image created thereby, but it remains invisible, and is therefore not impressive. On the other hand, development appears to do everything. Does not the image both appear and grow during and by means of development? Does it not seem obvious that if during development the print is growing too dark then the remedy necessarily must be the curtailment of development? The fact that the undesirable darkness of the print is caused by *over-exposure* does not occur to the beginner, and no one teaches him with the necessary emphasis that it is so caused. His ultimate realisation of this is the factor which determines his transfer from the class "beginner" to the class "expert," and coincides with the disappearance of most of the troubles in bromide printing. In that answer, involving a conclusion which appears on the surface to be perfectly logical, we can detect what I believe to be the failure on the part of teachers of photography to convey clearly to those who are learning the respective parts played by exposure and development in the production of a bromide print, and to emphasise the primary importance of the former and the secondary importance of the latter. There is no text-book, so far as I know, which makes it clear in simple language that if during development a print grows too dark then the defect is due to *over-exposure*, and has nothing whatever to do with development, and hence implies that the remedy is to give less exposure and not to curtail development.

The development of bromide prints by inspection fails because it provides no satisfactory safeguard against *over-exposure and under-development*, both of them utterly destructive of good quality.

There are many photographers who consider that the advice to develop to "finality" should be sufficient to make clear to the beginner the nature of his error and prevent him from under-developing an over-exposed print and regarding the result as the best that the negative will yield. The advice to develop to finality has the same basis as the suggestion that development should be carried on until the action appears to cease, and is practically similar to the suggestion that if development be allowed to proceed in half the print for a short time and then the rest of the print be submerged in the developer, development is complete when the portion of the print submerged last has caught up to the portion which was allowed to commence development first. By far the most common variant is that "development should be allowed to proceed until its action appears to cease," and Amidol has a special reputation for exhibiting this appearance of cessation in development. The opinion has already been expressed that the beginner will not believe this and act upon it, because with him it yields prints which are more or less black all over. This advice, however, labours under the additional disadvantage of being inaccurate. If a series of prints be exposed behind the same negative, each print being given the same exposure, and each print be given a little longer development than the one before it, using fresh developer for each, then there will be a steady progressive darkening with every prolongation of development long after the time of correct development has passed. The following prints (Table I) were made from a step plate, whose densities are given. Each print was given the same exposure, the absolute measure of which does not matter. The developer was Amidol, made up according to the Kodak formula. The temperature of development was 62 deg. F. The reflection densities of the prints were measured in the manner described by Mees, Nutting and Jones, "B.J.", January 1, 8 and 15, 1915.

There is obviously a continuous growth of density from prints A to D. On other occasions it has been stated that the factor for Amidol of the Kodak formula is 12. It will be noted that we have only to carry development further to yield a much darker print (C or D) without any fog. When development is carried on to a factor of 12 it has by no means ceased, nor does it "appear" to have ceased. There have been correspondents in the "B.J." who have challenged factor 12 as being too high. Let us assume that a factor of 8 is suitable. Obviously the case is even worse, and development at that stage is even less complete. We are far from cessation, either apparent or real, and far from "finality." The advice to develop until the action appears to cease in order to obtain a correctly developed print is, firstly, not credited and, secondly, not true.

TABLE I.

Densities of Step Plate. D_H	Exposure for each print the same. Time of first appearance of the image, 5 seconds in each print.				
	Print.	A	B	C	D
	Development time.	40 seconds.	50 seconds.	75 seconds.	125 seconds.
.325	Reflection densities.	1.15	1.40	1.475	1.475
.700		.93	1.15	1.375	1.475
1.125		.45	.725	.925	1.10
1.675		.12	.20	.30	.35
2.150		.01	.025	.05	.10
	Watkins' factor	8	10	15	25
	Fog strip ..	.00	.00	.00	.00

It will subsequently transpire that the exposure given to a bromide print is closely related to the development required. Good quality depends upon this relationship being correct. Development by inspection takes no cognisance of this relationship and often fails accordingly.

B. T. J. GLOVER.

(To be continued.)

PHOTOGRAPHING AT POULTRY SHOWS.—Photographing some prize birds at a poultry show some time ago (writes a correspondent), I had a very difficult task because of the fowls, etc., being very agitated and frightened while I was focussing my half-plate camera. One of the exhibitors told me his birds, and possibly the others, were frightened because of the colour of my focussing cloth—dark blue velvet lined with red. I laughed at the idea of the fowls being frightened, though I found they became less agitated when I put away the cloth and used my coat instead. I now learn from a newspaper that a number of sedate domestic fowls were nearly terrified out of their lives the other day because a red and blue kitchen table-cloth had been hung out to dry near their run. A fox could not have caused more disturbance. So there may have been something in the old poultry-keeper's idea after all. It is quite possible, however, that when the present craze for cretonne dresses dies out poultry will have become so accustomed to vivid reds and blues as to take no notice of them. The hint I have given will I hope be of service to those who have to take photographs of poultry.

OPEN ARC LIGHTS IN STUDIOS.—A special committee appointed by the Minister of Health have issued a report dealing with the injuries to eyesight alleged to be due to the powerful arc lights used in film-producing studios. The committee trace the trouble to the use of open arc lights without diffusing screens. They find that some transient eye injuries have thus been caused, but that there is no evidence of permanent damage to sight. They state that the evidence given them is to the effect that unscreened arcs are not only unnecessary, but give less satisfactory photographic results, and the Incorporated Association of Kinematograph Manufacturers have given an undertaking to the Minister of Health that its members will not permit the use of open arc lights without filters in their studios.

MIRRORS IN PHOTOGRAPHY.

PERHAPS in no other business is a mirror used more frequently than in a photographic studio. Its first place of importance and its usual "home" is the dressing room. Here "my ladye faire" can arrange her golden tresses and make herself pretty by its aid. The mirror and the maid, have been allied for ages. It is not on this theme I wish to dwell, but on other uses of the mirror in connection with photography. Mirrors have been used in some studios for what may be described as "novelty portraits," which were produced by combining a number of mirrors, to give four or five "views" of a sitter at one exposure, but there are further advantages to be derived by including one or more mirrors in the equipment of the studio or in the "outdoor" apparatus.

Nervous Sitters.

A good size "glass" (such as used in tailors' fitting rooms) at the end of the studio, *behind* the camera, can be of great help when nervous sitters are to be contended with. By careful adjustment before the sitter enters the studio, the posing chair can be reflected. After posing and focussing, the operator may tactfully turn away and watch, by the "reflected sitter" for his opportunity to expose. Many sitters are very nervous and do not like to be looked at when being photographed, and the above suggestion has proved very useful in such cases. The type of mirror used was a ¾-length glass, with the usual swing arrangement: being so far away from the sitter, there was not the slightest suspicion of the mirror being "in action," in fact, the sitter could not have seen herself in the mirror from her position before the camera; the result being a natural expression which would have been far more difficult to obtain otherwise.

Theatrical Work.

Where a considerable amount of theatrical work is done, the sitters themselves greatly appreciate a mirror near at hand during the sitting. For character studies the sitters generally desire expressions to suit the particular character. Actors and actresses pay great attention to expression in their portraits, and rightly so. With the mirror at hand the expressions may be practised, or rehearsed just before exposure. Theatrical clients find this a great help, as they are able to get any desired expression to the best effect, by using the mirror, and can retain the expression without the least sign of consciousness of "being photographed." As strongly as this suggestion is recommended in the case of photographing "professionals" it is certainly condemned when taking photographs of private individuals, because (in ninety-nine cases out of a hundred) as soon as a sitter tries to assume a natural expression, it is fatal to good results.

Private Sitters.

In some exceptional cases a mirror may be used for private sitters, but for a different purpose from the one mentioned above for "professionals." In this case, for general effect, in the composition of the finished picture, the mirror is used more or less as a background, and must be in such a position as not to reflect the camera when viewed from the lens. The best results are obtained by placing a dark background so that it is the only thing reflected, when viewed from the lens, and this reflection (background) should completely fill the mirror; and so we shall have (reflected) a good solid background for a head study; full face with profile reflected, or any other positions desired. Some very pleasing results may be obtained with suitable types of sitters. Children often give excellent opportunities for studies of this kind and, unconsciously, pose well. These studies are worked with the sitter close up to the mirror, and even touching it.

Fashions.

Having dealt with the large stand type of mirror so far, one more use of this same type will be in order. Mannequins, wearing standard fashions in gowns, etc., are often photographed for commercial purposes, catalogues, etc., the idea being to show each detail of prevailing fashion. A full length front view of a model wearing a gown is greatly appreciated by the costumier if a back view of the same is included. Obviously our scheme of reflection is useful in such cases.

Studio Lighting.

A mirror of the smaller type (for example a hanging wall glass about 12 by 10) is useful for obtaining very beautiful effects of lighting for head studies, full face preferably, in the following manner:—First, pose and focus in the ordinary way with plenty of front top light (not necessarily all top), when this stage is reached place the mirror on a low table (in front of the sitter) and tilt it so as to throw a strong light upwards on to the face. This system is seldom used, but is well worth trying as a fancy lighting and the writer has proved it to be very successful.

So much for the mirror and its uses in the studio. We will now consider its value in connection with the taking of commercial photographs. As one instance of a mirror being of great advantage, the following is worth noting: Having been called out to photograph an interior, I found one of the chief items of furniture in the room (outfitter's showroom and fitting room) was a large fancy stand mirror, as mentioned early in this article. The mirror *had* to be included in the view so I decided to make full use of it. The room was small, and there was not much space for displaying the numerous lines to be advertised. After arranging the goods in the space available, I reflected a plain ground into the mirror in the manner mentioned under the heading of "private sitters" in studio work. In this case I used a plain three-fold screen. After being sure that the screen filled the mirror, when viewed from the camera, I was able to build up a special display of other goods before it, and though neither the screen nor the goods were within the angle of the lens view the goods were displayed in the resulting photograph by reflection—which was greatly appreciated by the client.

Commercial Lighting.

To return to the subject of lighting, one often wishes for more light in certain parts of an object or interior to be photographed. For instance, a piece of heavy furniture indoors is often under a strong side light, one extreme end being lost completely in shadow, and running into the background. It is possible to overcome this difficulty by throwing light from a mirror. This local lighting can be controlled as required, which is a great advantage. With long exposures the mirror may be set to *reflect* the rays of light to local parts otherwise lost in shadow, during part of the exposure, and then shut off if desired, which is a useful scheme to get detail inside cupboards and dark corners, etc. By the same process, much brilliancy and detail can be brought out when photographing carvings. In such cases of local lighting, the mirror should be slightly moved about during exposure, to avoid harsh lights. Altogether, we can often benefit by the aid of a mirror in the practice of both studio and commercial photography.

PALLADIA.

SOME PROBLEMS OF COMMERCIAL PHOTOGRAPHY.

The problems which it is proposed to discuss are not those connected with materials or manipulation, but with certain aspects of the business, as distinct from the technical, side of the work. Furthermore, the writer does not intend to raise up hypotheses only for the purpose of showing his skill at proving or demolishing them. He cannot even find a solution for some of the problems which he will raise. To diagnose a disease without professing any ability to cure it has quite a respectable precedent in another profession, so that the writer has no qualms in following it. He is also at the moment in a position which allows him to take a somewhat detached, and therefore a less biased, standpoint; that is to say, that his work stands or falls by its quality. Speed is at the same time a fairly insistent factor, although it may be added that a description of both the nature of the subjects and the conditions under which they are handled have caused quite experienced photographers visibly to shudder and to commiserate the writer on his fate. The point on which he is often congratulated, however, and which is in some measure the foundation of these notes, is that cost comes only third on the list of points by which his work is measured.

It will add strength to the points that he proposes to discuss that, although it was actually the size of their photographic account that induced a certain large engineering firm to employ a photographer on their staff, his services have been demanded in so many ways that were not thought of before that the consumption of photographs is many times what had been imagined, and the actual sum expended must be very much greater also. It is this position which enables the writer very often to carry through a job in ways that would not be "economic" from the ordinary business photographer's point of view, and the problems that rise to his mind are as to what a man whose bread-and-butter depends on the profit he makes of his work would do in the circumstances.

The reader is asked to reject from his mind any idea which the previous sentences may have produced that the work referred to is done in a wasteful manner. The low percentage of time or material "wasted" in trials, overs, and throw-outs would astonish many whose work covers a very much smaller range of subjects or problems. What is meant by reference to economics and profit is merely that in the first place many small jobs are carried through that at current prices would not only not be worth handling by an outside commercial firm, but would be considered a nuisance and a loss. On the other hand, there is many an occasion when a better result can be obtained by using some special material, or a certain amount of extra time, the doing which by the outside firm might again result in a loss.

Again, I will ask the reader to cast out any supposition that in pointing out these facts the writer wants to claim any superiority, or to create any impression that he writes as though reclining on a metaphorical bed of roses. The facts are the reverse. In dealing with the many heads of departments he finds that the general opinion of photography and photographers held by these highly technical and professional gentlemen is that photography consists of certain camera manipulations which may be learnt (thanks to Mr. George Eastman) in half an hour or so, and that, judging by their circulars (both many and frequent) and by the dress and address of their representatives, technical and commercial, photographers are a shabby, touting lot.

That description is not a pleasantly sounding one, but the words are not the writer's. They represent the outspoken opinion of a gentleman who has business with many of the profession, and there are many other experiences that emphasise the popular opinion regarding the man behind the camera. Not only is he the butt of every "street-boy," but the grins that greet a photographer wherever his work takes him can hardly be said to add to his "professional" dignity. The portraitist is familiar with the busy city gentleman who can only spare three minutes for a sitting (though he probably spends many a pleasant post-lunch half-hour with a glass and a cigar), as "he is already late for an appointment with his dentist," and is subsequently surprised to find that his expression in the photographs accords with those circumstances. The same attitude is frequently adopted towards the commercial photographer, who is handed, let us say, a complicated scientific instrument, and is asked to "Just *snap* this, will you?"

On the other hand, one occasionally meets people who recognise that photography is a craft calling for as much skill and time as any other, and that the craftsman is worthy of his hire. Just recently the writer was asked to photograph a stained-glass window which contained, perhaps, an unusual range of colour, from the palest tints of mauve and even white rolled glass to deep browns, reds, and purples, besides embodying a vast amount of exceptionally fine detailed hand-work; in short, a regular "teaser." Yet the designer was willing to pay any sum in reason for a print to be subsequently reproduced in a half-tone block. A straight proof from the whole-plate negative evoked astonishment as to amount of detail and gradation rendered, but a subsequent half-hour with matt-varnish, pencil, and scraper made a 50 per cent. improvement. Occasionally also a firm will pay one's expenses to travel many miles in preference to engaging a local photographer, although the latter's prices may be much lower. The inference is pretty obvious, but the trouble seems to be that those who have learnt the advantage of paying a good price are few, and have arrived at that result by reason of their own bitter experience, and not by reason of any activity on the part of photographers. Cutting of prices seems to be rapidly becoming a feature of business-fetching tactics among commercial photographers as it was, not so many years back, among the portrait artists. It will be recalled that commercial work was often regarded as a refuge from the impasse that resulted, but itself appears to be approaching the same state of affairs.

The writer has already explained that he is not immediately affected by the cutting of prices, or by the accompaniment of wage reduction, which are always two sides of a very vicious triangle. He has been, however, in the course of "keeping his own end up," to a certain degree successful in his immediate entourage in correcting the impression described at the commencement of this screed, that photography is little more than a button-pressing profession. One of the useful results of his efforts has been to prove that given a well-finished article and reasonable facilities for photographing it to advantage, the block from an untouched print will give a much more faithful and effective representation of the subject than one made from a photograph of an unfinished or soiled article just stuck up anywhere in the workshop and "snapped," and afterwards worked up by a process-artist. In addition to being better it is considerably cheaper as a rule.

In connection with this point it may be mentioned that the writer is informed that a well-known process firm is quoting an absurdly low price for making a whole-plate negative and print, probably relying on the necessity which will arise as a result of cheap work for a very great deal of highly priced artists' work to bring them a satisfactory profit. There are other interesting problems that concern the question of a fixed price per photograph, from the point of view of the operator. Frequently, probably more often than not, it happens that the price quoted is calculated on the time that should be taken normally in setting up the camera, taking the photograph, and in the return journey. In the writer's experience it happens, also more often than not, that to spend more time than would be "economic" as regards the price quoted would result in a better photograph. It may be a house, and a little waiting would bring the sun into a more favourable position. It may be a machine, on which the operator would like to spend some time with chalk or an oily

rag, or it may be desirable to have it moved about and some sort of background rigged up to make subsequent blocking-out easier. On the other hand, many mechanical subjects which usually are required with an absolutely white background are much better rendered if actually photographed against a fairly dark ground, with only just a bit of white paper to give a defined outline of some complicated portion, and afterwards blocked out with opaque, but the price quoted may not have included this operation. Just how to get the best results from each subject should always be a matter for the operator's skill and judgment, but what is he to do in such cases as those suggested, which are only examples of what frequently occur? If he studies time the client does not get the best possible photographs, which fact is bound, sooner or later, to react on the operator's wages and prospects, though that effect may arrive only gradually and indirectly. If, on the other hand, he goes all out for the best possible photographs, his employer will grumble at the time spent and the loss of immediate profits, and the customer will complain if the additional expense above the original quotation be passed on to him.

To the writer it seems far pleasanter and more profitable to aim at a satisfactory price for the best possible work. The customer appreciates the fact, *if it is made apparent to him*, that the cost of good photographs is not so much above that of inferior stuff that it will not be very quickly recovered many times over by its increased advertising power. It may also be shown, as has been suggested above, that the more expensive photograph may be actually cheaper, because it needs no working up. Better prices, as well as the increased business that well-satisfied customers usually induce, are not generally regarded as undesirable by photographic firms, nor is an increased wage, which such circumstances should permit, likely to be objected to by the operator.

The writer's aim in penning these remarks has been to show that good photography is regarded by a comparative few of the public as a skilled "profession," and as such worth a satisfactory fee. By the great majority it is regarded merely as little more than an easily learnt elaboration of a popular hobby. It is to the interest of all that public opinion should be educated up to the facts. Having attempted to describe some of the symptoms of the ailment from which the profession of commercial photography is suffering, and to suggest some of the causes, the writer hopes that someone may be able to devise a remedy.

D. CHARLES.

THE THEORY AND TECHNIQUE OF LIGHT-FILTERS.

[The following is an important paper on the principles of the action of light-filters and on the practice of their preparation and use. It is the work of a Russian physicist, M. G. V. Potapenko, and was first published in the Journal of the Russian Physical and Chemical Society (Chemical Section) 1916, vol. 43, p. 790. We owe the accessibility of the paper to Dr. C. E. K. Mees, by whom the translation from Russian has been made. Dr. Mees while rendering the text into English, does not thereby wish to imply his agreement with everything contained in it. He has refrained from exercising a translator's right of commentary except in one or two instances which particularly call for correction. The fact that he has made the translation and given us the opportunity of publishing it, may be taken as an indication that he regards the paper as a contribution to the literature of light-filters of exceptional value.—EDS. "B.J."]

THE use of light-filters for all scientific purposes has increased greatly of late years. Physicists, astronomers, chemists, doctors, all make use of them to obtain monochromatic rays of light. Botanists employ them to study the influence of light of various colours on plant light. For use in three-colour photography it is of the greatest importance to obtain a series of standard and permanent filters.

In spite of the widespread use of light-filters we have not up to the present time any definitely worked out directions for their preparation, the scattered articles on the subject, distributed as they are in specialist journals, often dealing in duplication with one and the same problem.

In foreign literature we may refer to two papers, those of Dr. Grebe[1] and of Von Hübl, but these contain only the most elementary directions for those who desire to make light-filters, and omit many technical details of the work, in which many difficulties are likely to occur in practice. It is our purpose therefore to deal first with the material accumulated up to the present time, and then to point out the simplest working methods suitable for those who wish to carry on investigations in this field. In spite of the small amount of work available regarding the preparation of light-filters, their history dates from the beginning of the 16th century, and since that time many references to them have appeared in the literature, these including a great number of formulæ, often repetitions of each other, relating to the various types of light-filters which the authors have used in their investigation. The first reference to light-filters is that of Leonardo da Vinci[2] (d. in 1519), who used coloured glasses for the study of his paints. Following this, coloured glasses, which were the only light-filters known at that time, were used for a long time in occasional scientific investigations relating to colour and colour-blending, but not until Becquerel's[3] time were they used generally.

Hunt and Abney[4] devoted much attention to the study of the absorption of light in coloured glasses, and these investigations have been continued up to the present time.

Maxwell[5] in 1861 first demonstrated in London the three-colour projection of photographic images, and thus laid the foundations for photography in natural colours in accordance with the Young-Helmholtz theory. At about the same time experiments were made on the preparation of liquid filters from organic and inorganic coloured substances, and also on light-filters prepared in the form of films. These latter for some time were made from dyes dissolved in collodion or celluloid, but towards the end of the last century these began to be replaced by the technically better gelatine films. Dr. Castracane, Zettnow, and Gifford[6] employed light-filters for microscopic and photomicrographic investigations. E. Pringsheim and Nagel[7] introduced them for biological and botanical work, and it may be said with full justification that at the present time there is no field where light-filters are not employed. At the beginning of the present century light-filters were so widely employed that Grebe[1] attempted to arrange them according to a definite system and to make an accurate classification of them. His classification could not be generally adopted in science, for he classified filters according to the field of investigation and the purposes for which they were used, so that the filters were designated as photographic, optical, bolometric, etc., and one and the same filter might have several names if it were used for various purposes. It is preferable to classify light-filters according to the form of their absorption curves, and it is this method which is adopted in the present discussion.

At the same period the first exact quantitative measurements of the absorption of light by filters were made by A. Callier[8] and Monpillard[9], thus establishing the first step towards the solution of the problems bearing on the theory of light-filters which exer-

cised a great influence on all further work; since the estimation of the absorption by such terms as "weak," "scarcely visible," etc., was considered unsatisfactory, and was replaced by numerical data obtained by the measurement of the filters spectrophotometrically, resulting in exact quantitative determinations of their absorption for light of definite wave-length.

In the preparation of dry filters in film form, gelatine solutions are often used for carrying the dye, but the precision of measurement is scarcely sufficient to enable a definite conclusion to be reached as to whether the gelatine acts towards the dye as an indifferent medium, is simply a "carrier" of the dye, or whether it exerts a definite influence on the shape of the absorption curves, thus producing what have been termed "shifted" curves, changing the resulting filter.[10]. The definite determination of the influence of the gelatine still requires further investigation.

Absorption of Light by Filters. Classification of Light-Filters.

By the term "light-filter" is understood any medium which exercises selective absorption, that is, which is able to absorb from the rays of light which fall on it those whose wave-lengths fall within certain definite limits; the term includes also those media which absorb rays of all wave-lengths, but not to the same extent: in practice we are concerned only with the latter type of absorption, since all bodies are capable of absorbing light-rays falling upon them, and none are perfectly transparent.

The reflection of light from the surface of a filter which is involved in the determination of its transparency follows for rays incident normally the formula of Fresnel.

$$I_d = \left(\frac{n-1}{n+1}\right)^2 I_0 \qquad (1)$$

where I_0 is the intensity of the light falling on the surface of the filter, and I_d that of the light transmitted, n is the refractive index of the medium of which the filter is made, and it is therefore evident that

$$I_d = f(\lambda).$$

Let us consider this in detail. In the simplest case consider the filter as a medium limited by a pair of parallel planes, and let R be the part of the light reflected from the surface of the filter according to equation (1). Then we have for the quantity of light entering the filter

$$I^1 = I_0 (1 - R).$$

from which some part A will be absorbed by the medium, and on the second surface of the filter there will be incident an intensity

$$I^1 (1 - A).$$

From the second surface there will also be reflected a quantity which it will easily be seen is also R, since the value given by equation (1) is not changed by the substitution of $1/n$ for n. The emergent beam has the intensity

$$I_1 = I_0 (1-R)^2 (1-A).$$

The light

$$I_0 (1-R) R (1-A)$$

reflected from the second surface of the filter returns to the first surface, which it reaches reduced to the intensity

$$I_0 (1-R) R (1-A)^2.$$

Here again reflection is undergone, part of it will pass on, and it is easily seen that after a second reflection from the second surface of the filter of rays of an intensity

$$I_0 (1-R) R^3 (1-A)^3$$

there emerges from the light-filter an additional quantity having the intensity

$$I_2 = I_0 (1-R)^2 R^2 (1-A)^3.$$

The reflected light

$$I_0 (1-R) R^3 (1-A)^3$$

will add to the beams I_1 and I_2 an amount I_3, and so on. Continuing this reasoning, we find that of the total incident light intensity I_0 there emerges the fraction,

$$I = \sum_1^{\infty} I_k$$

but since I_2 is already negligibly small we can retain the first term of the series only, and write

$$I = I_1 = I_0 (1-R)^2 (1-A).$$

And since in practice the surface of the filter is generally of glass, for which approximately $n = 1.5$, we have by formula (1)

$$R = \frac{I_d}{I_0} = 4\%$$

that is only 96 per cent. of the incident light can on the average enter the filter while the remainder will be lost.

The value of R can be measured spectrophotometrically instead of calculating it, or can be eliminated without measurement.

In the determination of the total absorption of the filter R is often neglected and the absorption is often expressed as the ratio

$$\frac{I_0 - I}{I_0}$$

while more correctly the value is

$$\frac{I_0 (1-R) - I}{I_0 (1-R)}$$

The absorption of light in a coloured solution, such as a liquid filter, is according to Beer's law

$$I_x = I_0 e^{-Kcx} \qquad (2)$$

where the co-efficient K is termed the absorption constant; c is the concentration and x the thickness of the layer; I_0 and I_x are the intensities of the incident and emergent light.

If a dry (film) filter be substituted for the liquid one the formula assumes a simpler form. In this case C will be the amount of dye per unit area and x will be included in the value of c. Thus I_x will be only an implicit function of x, and the formula becomes

$$I = I_0 e^{-Kc} \qquad (3)$$

A number of dyes are now known not to obey Beer's law (2), *i.e.*, for these dyes the value of K is not independent of c.

Few observations of light-filters in the form of films have been made and no departures from Formula 3 have been observed. On the contrary, the results obtained by Von Hübl[11] indicate that dyes in dry gelatine films obey Beer's law even when their solutions in water do not, acid rhodamine being an example of such a dye.

The absorption constant K is always a function of the wave-length of the light and the curves corresponding to the equation

$$K = f(\lambda) \qquad (4)$$

are continuous for all dyes which have been examined and show fairly regular, almost periodical waves.

If the values of the constant K be determined experimentally for a number of points in the spectrum it is possible to obtain the value for any desired wave-length by interpolation, since the function is continuous, this may be done algebraically if the function is known or graphically by plotting the measured values and joining them to form a continuous curve.

In future we shall call this curve the absorption curve of the dye considered.

The concentration of the dye c may be stated in any desired units. Monpillard[12] suggested that it should be expressed in grams per square centimetre of the surface of the filter, but the figures so obtained are inconveniently small, and Von Hübl therefore selected as a practical system of units grams per square metre of the surface. Eder[13] suggested that this unit, 1 gram per square metre, should be called Hübl's Unit, and designated by the symbol H, a suggestion which has been adopted by many workers and which we will follow.

In equation (3) we may substitute decimal for natural logarithms and write

$$I = I_0 10^{-ec} \qquad (5)$$

If $e = mk$ where m is the modulus, 0.4343. The quantity e determined spectrophotometrically enables the absorption of energy by a light-filter to be expressed in percentages. Plotnikoff suggested that to distinguish it from the first absorption constant it should be termed the absorption coefficient. (Bunsen termed this the extinction coefficient.)

Let I_0 represent 100 units of intensity, then in our notation

$$I_0 - I = A \qquad (5^1)$$

whence

$$A = 100 (1 - 10^{ec})\ \% \qquad (6)$$

and since e is a function of the wave-length

$$A = \phi(\lambda) \qquad (7)$$

The curve corresponding to this equation for any light filter is called the absorption curve, and expresses the same property as the curve corresponding to equation (4), like which it is continuous. It can easily be seen *a priori* what differences will exist

10. A. Hübl, *Die Gelatine für Phot. Lichtfilter*, Phot.-Rundschau, 1912 p. 9.

11. A. Hübl, *Die Phot.-Lichtfilter*, p. 18.

13. Eder, Jahrb. 1913, p. 280.

between curves (4) and (7). If a light-filter is made from a single dye having a concentration $c = 1$ H, its absorption curve will be identical with the curve of the absorption constant of the dye, if we neglect the absorption of the gelatine, which is very small. Light-filters are generally made from a mixture of several dyes so that the values of the ordinates of the curve (7) will be functions of the ordinates of the corresponding curves (4) of the individual dyes.

In accordance with their absorption curves all filters can be classified into three groups.

1. Monochromatic filters selecting any narrow part of the spectrum, *i.e.*, transmitting a narrow bundle of rays of the same colour.

2. Compensating filters which are used to correct the colour rendering given by photographic materials.

3. Subtractive filters absorbing a small part of the spectrum, *i.e.*, having a curve exhibiting selective absorption.

As examples of all three groups let us examine their absorption curves, plotting as abscissæ the wave lengths λ and as ordinates the absorption coefficients ε and remembering that when $I_0 = 1$

$$E = -\log_{10} I$$

or

$$E = -\log_{10} (1 - A) \qquad (8)$$

as can be easily seen from formula (5) and (5¹) when $\varepsilon c = E$.

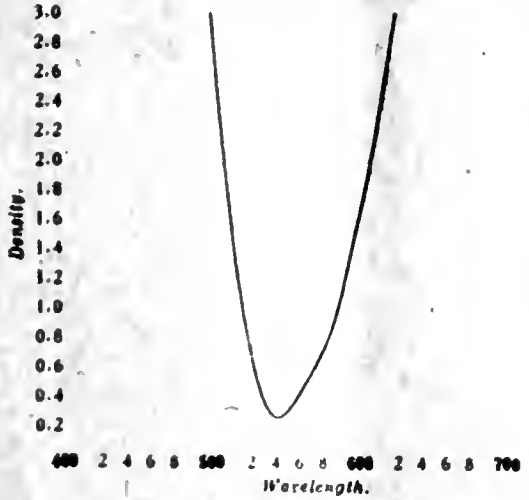

Fig. 1.—Three-colour green-filter.

In Fig. 1 is given the absorption curve of a green filter for tri-colour photography (König's Additive Filter);[14] the concentration of the dyes are

Patent Blue[15] ..... 0.4 H.
Tartrazine ..... 2.2 H.

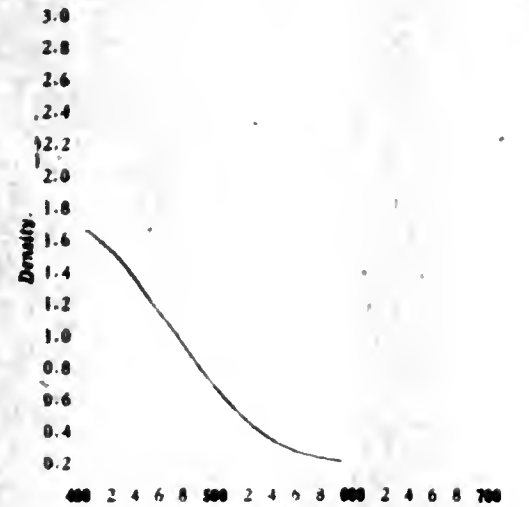

Fig. 2.—Yellow compensating light-filter.

15. The names of the dyes are those given by the Höchst Dye Works, who supply them.

Fig. 2 shows the characteristic appearance of the absorption curve of a yellow compensating filter for orthochromatic emulsions.[16] And, finally, Fig. 3 gives the absorption curve of a subtractive filter prepared from

Rose Bengal ..... 0.2 H.

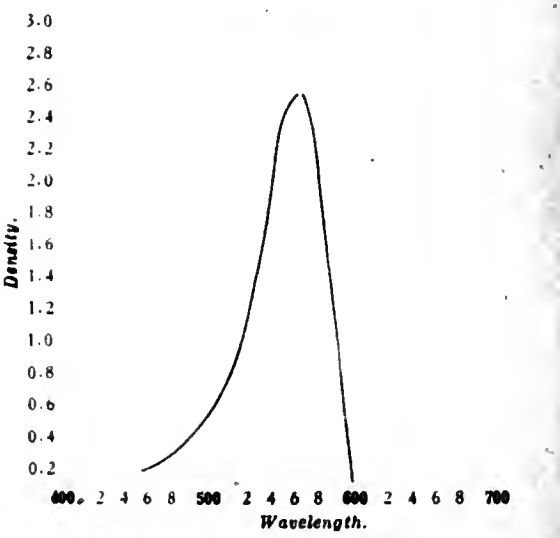

Fig 3.—Rose Bengal subtractive filter.

The curves of filters 1 and 3 are complementary to each other. A monochromatic filter transmits only a narrow part of the spectrum, while a subtractive filter absorbs an equally narrow part of the spectrum. Curve 2 for the compensating filter is seen to be intermediate between the 1st and 3rd.

Grebe[17] used at first a similar classification, but he added to the above-mentioned groups two others, protective filters and contrast filters, but the first (especially the red and green filters used with photographic emulsions) belong to the group of monochromatic filters since their absorption curves are of the same type, and the second group may be sub-divided into monochromatic and compensating filters.

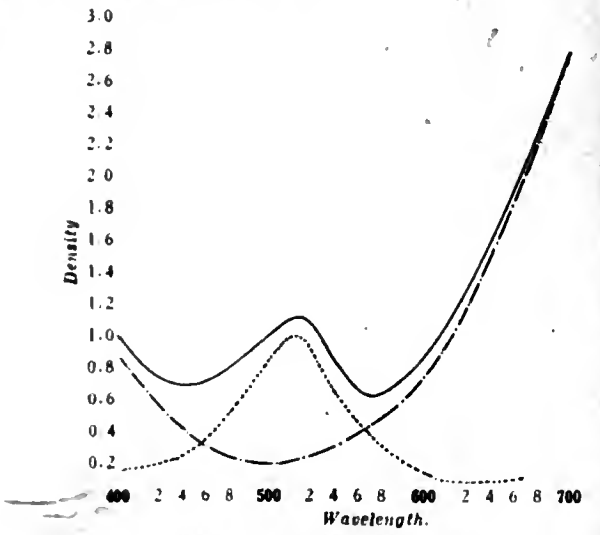

Fig. 4.—Nickel and cobalt filters.

Absorption curve of nickel chloride in concentration 2400 H. – – – – – –
Absorption curve of cobalt chloride in concentration 800 H. .....
Absorption curve of mixture ————

A special group includes those filters which transmit two regions of the spectrum of complementary colour, *i.e.*, those which, by transmitted light, appear neutral grey or faintly coloured; the light transmitted by them appears to be colourless. In 1890

16. Callier, Rev. des Sc. Phot., 1900, p. 612.
17. Grebe, Phot. Korr., 1900, p. 612.

Liesegang[18] showed that if we mix a solution of cobalt chloride $CoCl_2$, which has a red colour, with a solution of nickel chloride, $NiCl_2$, whose colour is bluish green, the light transmitted by the mixture appears colourless or, more exactly, a very weak yellow. Von Hübl[19] examined these solutions in detail, and from his absorption curves it is clear that with the concentration

$NiCl_2$	2400 H
$CoCl_2$	800 H

the orange and blue light is transmitted to a greater extent than other colours, and thus the filter appears neutral.

Since these colours are not exactly complementary the neutral grey obtained is of a yellowish shade. Gelatine films of similar neutral colour were prepared by Von Hübl from naphthol green and fast red D. Obviously other combinations of dyes can be found whose colours are complementary.

A difficult problem is presented by the selection of dyes for monochromatic filters; since only those are satisfactory whose absorption curves are steep otherwise the filters will be insufficiently transparent for the rays which they transmit. The firm of Wratten and Wainwright issue from their laboratory a series of narrow monochromatic filters, but all these display the above-mentioned defect.[20]

Many dyes cannot be used for the preparation of dry filters since frequently they crystallise out on the surface of the filter in drying, and the use of liquid monochromatic filters would appear, therefore, to offer advantages. Landolt and Nagel[21] give a series of such filters. A very complete investigation of liquid monochromatic filters was made by Pretzl[22], following whom Popowitzky[23] gave a series. Dry monochromatic filters were made by Tikhoff.[24]

(*To be continued.*)

RELATIVITY IN PHOTOGRAPHY.

The Einstein theories, over which the scientific world continues to flutter itself, may not, perhaps, be accepted in their entirety by everybody. They involve, however, a fundamental truth too often neglected, namely, that all phenomena should be examined and analysed from every possible point of view, instead of being, as it were, classified, pigeon-holed, and dealt with from a single limited aspect. We receive, also, a useful reminder that even long-established laws are not necessarily absolute and infallible, but are often found to break down, or to fail in exactness, through neglect of some unknown or overlooked factor. The photographer, in company with the astronomer and physicist, may profitably examine his daily practice, in search of any omission on his own part to recollect the relativity or inter-relationship, of things.

The importance of psychology, which is simply a mental adjustment of relativity in its personal outlook, in attracting sitters to the studio and intelligently handling them when there, has already been pointed out, and need not here be referred to.

The relativity of the operator's own view-point, as compared with the position of the camera lens, often receives insufficient attention. Whatever he may fancy, an upside-down image on the ground glass affords but little guidance, while the facts gained by an actual inspection of the subject may be quite misleading, since the operator generally steps out a foot or so to one side of the camera, and his head is also usually higher than the lens. This not only interferes with a really accurate judgment of the pose, but even subtly modifies the lighting and expression. As the sprightly young Barnacle says, in "Little Dorrit": "You don't regard it from the right point of view. It is the point of view that is the essential thing."

Much of that vague disappointment so frequently felt by the photographer at the discrepancies between his results and his anticipations is really due to the foregoing cause alone. Practically speaking, the uncertainty and disparity can only be overcome by the use of a reflex camera. The portraitist of Daguerreotype days, when the sitter was perched on a raised platform to bring him nearer the skylight, appears to have realised the difficulty, as far as height is concerned, since old engravings show that the steps on which the operator himself mounted were always lower than the platform.

The focal length of the lens is another important factor. An unduly short-focus lens used for portraiture will introduce apparent distortion in the nearer parts of the subject, owing to the close view-point. This, again, is an effect of relativity rather than unreality, since the results so obtained would appear correct if held at a distance from the eye equal to the focal length of the lens, or if taken with a pair of identical lenses and inspected in the stereoscope.

The relativity of the shutter, too, needs consideration. A press photographer, for instance, caused surprise lately among his coterie of friends by expressing a preference for a fast type of diaphragm shutter over the focal-plane, on the somewhat novel ground that it gave better definition. This was hotly disputed, but a little reflection should have shown the perfect correctness of the statement, since the diaphragm shutter, for an appreciable part of the exposure, acts as a small stop. The curious diversity sometimes met with in different focal-plane photographs of the same subject, according to the direction in which the blind was travelling, and the occasional travesties of possibility seen in projected cinematograph films, such as cab-wheels moving backwards if they happened to be running at a certain speed when taken, are further examples of shutter relativity.

Then there is the relativity of the exposure to the correct rendering of contrast and tone values. Every operator knows how under-exposure increases contrast and diminishes the shadow detail, while over-exposure reduces contrast and has a general flattening effect. What is not always so fully grasped is, how vitally the features and expression in a portrait may thereby be affected, so that the result ceases to be truthful. The lines, wrinkles and hollows in a somewhat strongly-marked face are hideously and exaggeratedly emphasised in under-exposure; whereas, in over-exposure, the tendency is the other way, and what little character may already be present in rather inane features is tamed down and extinguished. Obviously, the hint is not without its value, since it enables us to give more firmness to a flabby, vapid face by slight under-exposure, or to soften undue asperities in a stronger one by over-exposing a trifle.

The relativitiy of orthochromatism to a faithful and convincing record need scarcely be insisted on. The use of orthochromatic plates and films in studios is, as might be expected, steadily on the increase. The employment of a screen is not always practicable, on account of the lengthened exposure, but even without one the results are distinctly superior to those on ordinary plates.

A faithful depiction of the orginal light and shade in the subject depends not only on reasonably correct exposure, within the latitude of the plate, but on the duration of development, since this will affect the contrast. Yet the amount of contrast desirable is, to some extent, a matter of relativity, as it will vary in the final result according to the printing process. A negative not contrasty enough for a bromide print may still give an excellent result with a vigorous gaslight paper. Indeed, there is now such a wide range of rapidities and surfaces to choose from, capable of so greatly modifying the ultimate effect, that it becomes rather a bold venture to declare too dogmatically whether the negative of any given print was good or bad.

Relativity is even more startlingly evident in the mutual opposition of mount and print. The self-same photograph may be made to seem darker or lighter, warmer or colder in tone, by mere variation in the depth and tint of the mount. An amusing tale is being told by a well-known worker of a lady who brought back all her photographs, alleging that they were far too dark and heavy. Not wishing to have them printed afresh, and noticing that the mounts were comparatively light, the astute proprietor had the pictures detached and placed on mounts darker than themselves. This time the photographs gave every satisfaction, the fair sitter declaring how much better they were than "those other things!"

It will be seen that relativity plays a much larger part in photography than many might imagine, influencing, qualifying, or radic-

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 8 to 13

PHOTOGRAPHY.—No. 21,278. Photography. W. P. Carpmael.

REPRODUCTION METHOD.—No. 21,383. Photographic reproduction of pictures, etc. W. E. Masson and N. S. H. Sitwell.

REFLEX CAMERAS.—No. 21,000. Device for a folding reflex photographic camera. S. S. Roberts.

FINDERS.—No. 21,366. Focussing devices and distance-finders for photographic cameras. J. H. Whitehead.

STEREOSCOPY.—No. 21,572. Camera for taking stereoscopic pictures. J. C. Wichmann.

APPARATUS.—No. 21,006. Photographic apparatus. F. E. Hoffman.

COLOUR PHOTOGRAPHY.—No. 21,554. Colour photography. W. van D. Kelley.

CINEMATOGRAPHY.—No. 21,275. Method of manufacturing non-inflammable cinematograph films. R. A. McJunkin.

CINEMATOGRAPHY.—No. 21,074. Cinematograph films and methods of making pictures thereon. J. E. Thornton.

CINEMATOGRAPHY.—No. 21,077. Printing cinematograph films, etc. J. E. Thornton.

COLOUR PRINTING.—No. 21,075. Colour printing. J. E. Thornton.

COLOUR CINEMATOGRAPHY.—No. 21,076. Multi-colour cinematograph films and methods of printing and manufacturing same. J. E. Thornton.

CINEMATOGRAPH-PHONOGRAPH.—No. 21,243. Apparatus for producing synchronous cinematograph and gramaphone records. A. J. D. and J. W. Spark.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

VACUUM STORAGE OF PLATES OR FILMS.—No. 163,661 (January 7, 1920). The invention relates to a method of (and container for) preserving sensitive plates or films, and consists in placing the films or plates within a container and sealing the container under a vacuum.

For example, a film spool may be placed in a container which is sealed while under a vacuum. Plates may be similarly stored. —Francis Patridge McColl, Ridgewood, New Jersey, United States.

LANTERN SCREENS.—No. 166,015 (May 19, 1920). The invention consists of a cinematograph screen constructed of a sheet of polished plate glass coated on its rear side with a white pigment applied direct to the glass to act as a reflector.

The screen is constructed of plate glass, preferably having the greenish tinge which plate glass usually has, and the glass should, of course, be free from blemishes, and perfectly plane.

The glass, after having been carefully polished, is provided on its rear side with pigment, e.g., zinc sulphide mixed with a solution of sodium or potassium silicate, of a strength of not less than 30 deg. B., is found to yield the best results. In order to prepare the screen, the glass is suitably supported, and the pigment flowed on to it, and the mixture allowed to dry, the action of the alkaline silicate being to bind the pigment to the glass, the whole mass becoming like a hard enamel, securely attached to the back of the glass. Other white pigments, not acted on by the atmosphere, can also be employed mixed with the alkaline silicates referred to, such as, for example, finely ground glass or white precipitated calcium sulphate. When the pigment has completely set, the plate is preferably mounted in a frame of wood, metal, or the like, and the back covered with any suitable moisture-proof protective covering, such as moisture-proof paper, varnish, or the like.

The pictures are projected on to the uncovered side of the glass plate. It is found that the greenish tinge usually present in plate glass produces a restful and soft effect to the eye, whilst the glass itself has the effect of bending the light towards the observer, so that where a screen of this type is used, the picture can be equally well seen from practically all angles in front of the screen, whereas with the ordinary type of screen, those observers sitting in the centre of the room or hall obtain the best view of the picture, which latter is apt to be distorted when viewed from the sides.—Robert Gilpin, 22, Homewood Villas, Gander Green Lane, Sutton, Surrey.

LANTERN SCREENS.—No. 166,067 (October 8, 1920). The fabric is covered by priming coats of starch and liquid glue, and by subsequent successive coats of paint, the first of which consists of old linseed oil, zinc white, oil of turpentine, and driers, and the second coat of which consists of zinc white, ultramarine, ivory black, linseed oil, oil of turpentine, and driers, each of the coats being flatted with glass paper when dry, and the last coat being treated with a gilding mixture, which is likewise flatted, and, when dry, is padded over with a mixture of metallic powders.

A method of preparing a fabric screen is:—1. The fabric is primed with a coat of liquid starch, applied with a sponge. 2. When dry, this coat of starch is covered—also by means of a sponge—with a coat of glue, melted in a water bath.

The object of these two operations is to prevent the subsequent coats, which have a basis of linseed oil, from penetrating into the fabric.

3. After drying, a first coat of paint is applied, composed of zinc white, matured linseed oil, oil of turpentine, and driers. When this coat is quite dry it is smoothed with glass paper. 4. After this flatting process, a second coat of paint is applied, composed of zinc white, ultramarine, ivory black, linseed oil, oil of turpentine, and driers. This coat, which is pearl-grey in colour, also forms a dull ground, and is likewise flatted with glass paper when dry.

The resulting surface is smooth and uniform.

5. A metallising coat is next applied, composed of gold size, to which 100 grammes of aluminium powder and 50 grammes of silver powder have been added per litre of the mixture. 6. When dry, which takes about 24 hours, the surface is padded with a mixture of 80 per cent. of aluminium powder and 20 per cent. of silver powder, applied dry with a pad of cottonwool. The resulting surface is perfectly bright, free from spots or streaks, and the adhesion of the metallised coat is absolute.—Joseph Coutelier, 23, Rue Jolly, Brussels.

METAL BINDING FOR PHOTOGRAPHS.—No. 166,858 (December 23, 1920). A strip of metal having a series of serrations or scollops along both edges is used. This strip is adapted to be folded over upon itself so as to embrace the edges of the photograph or other card to be framed. Owing to the serrated edges, the strip may be readily bent round corners or along the edges of round, oval, or other curved cards, whilst the serrated edges also provide a decorative effect.

The serrations along the edges of the strip preferably extend to within a short distance of its centre, a thin strip down the centre being left quite plain. This strip may conveniently be of

a width about equal to the thickness of the average card to be framed.

The photograph or other card to be framed is provided with a transparent cover, which may be readily cut to the outline of the card. The metal strip is then applied, and bent over the edge and pressed down upon the back and front thereof; so as to securely clamp the cover in position.—Siegfried Henry Kaufmann, 42, Tottenham Street, Tottenham Court Road, London, W.1.

Cinematograph Colour Printing.—No. 130,603 (July 26, 1917). The machine comprises step by step feeding means, and registering pins, independent of the feeding means, one of which passes through and completely fills one perforation in the positive and a corresponding perforation in the negative.

The registering pin means is mounted so as to be reversible whereby in printing on opposite sides of a positive from different negatives the shrinkage of the latter is taken up relatively to the same perforation or perforations in the positive.

The feeding means is bodily movable to effect the feeding of the strips, and is operable to engage the negative strip only, or both the negative and positive strips, during successive movements.—William Van Dorn Kelley, 1586, East 17th Street, Brooklyn, New York State, and Joseph Mason, 712, East 175th Street, New York.

Substratum for Emulsion on Metal.—No. 14,344 (June 15, 1914).—A coating is applied to the metal surface of a mixture of gelatine and potassium silicate or sodium silicate (soluble glass).

To harden the coating, formaldehyde or alum may be added to the substratum mixture.—Michael Werthen, 5, Germaniastrasse, Munich, Germany.

Waxed Paper Emulsion Stripping Base.—No. 166,686 (April 19, 1920). The invention relates to photographic transfer processes in which a photographic image is transferred from a paper support on which it is originally made to any desired surface such as, for example, a special paper or a surface of wood, porcelain, glass, fabric.

A paper support is employed, impregnated with a solution of paraffin wax, such solution being so weak as to leave the paper surface apparently free of any continuous layer of wax, and the emulsion is then applied directly to the surface of the paper so treated. It will be found that while the emulsion adheres sufficiently to the paper support to allow of the usual photographic manipulations, it is readily separated therefrom when applied to the surface of the final support.

It is essential that a very small amount of paraffin wax should be employed and a weak solution is therefore necessary, *e.g.*, about four or five grains of paraffin wax in one ounce of benzol or other solvent. Such a solution sufficiently impregnates the paper with wax, the amount of which may be varied according to the texture of the paper employed, and enables it to carry a photographic image which leaves the waxed paper temporary support upon transfer to any suitable substance.

The paper is either dipped in or passed through the weak wax solution. The emulsion is then applied thereto in the usual manner after evaporation of the wax solvent. The transfer of the print on to the paper, wood, glass, or other surface is then effected in the ordinary way, and the transfer image or print then separated from the original waxed paper temporary support.—Thomas Albert Mills, 72, Manor St., Clapham, London, S.W.4

Colouring Carbon Prints.—No. 146,134 (January 31, 1919). The invention relates to a process for the colouring of carbon prints by painting them with albuminous glaze colours, and subsequently applying a strong solution of asphalt in any suitable medium. The solution has a dark brown colour and gives a coating of the same colour, which is, however, transparent. Then the bright or lighter portions of the picture are wiped out in successive stages. When the initial tinting is being done, the tone values must be made to appear much more intense than in the original, as they are reduced to their proper values partly by the tone values of the carbon print and partly by subsequent treatment.

In pictures not containing large portions showing one and the same colour the colouring with albumen-glazing colours and the subsequent coating with asphalt is sufficient. Before, however, colouring an adjacent portion, the portion already painted with albumen colour must be protected in order not to destroy it in the subsequent wiping operation. This is effected by spraying on to the large portions painted with albumen glazing colour a solution of resin or mastic in alcohol, after which, in order to connect the several portions of the picture with each other well, the solution of asphalt and resin in oil of turpentine is applied, the colour depth of the solution being so selected as to be equal to the darkest part of the original. Then the lights, *e.g.*, as clouds, are wiped out and smoothed down with the softening or shading brush, and then again the brightest of the remaining parts are wiped out, and so on, until through this continuous brightening or setting off the impression of the shaded original is attained.

Larger surfaces, especially those strongly coloured in the original, which are fairly uniform, that is to say, poor in detail, after the initial colouring with transparent albuminous colours as previously described, may require an additional colouring, which is done with oil colour. As the transparent colour has combined with the bichromated gelatine layer the translucent or transparent oil-colour layer or coat remains thereon. The corresponding oil colour is applied as a glazing colour without exact observance of the outlines, and is uniformly distributed with the softening brush, whereupon the outline is wiped out with a rag and again treated with the softening brush. The oil colours employed are varnish colours in contradistinction to opaque colours. In this way the relief effect of the original is more fully apparent and gives the appearance of a freshly painted picture, without the reproduction having the undesired character of a coloured photograph. After drying, an alcoholic shellac or mastic solution is sprayed on, leaving a transparent resin coating behind. Finally an asphalt layer is applied to the whole, prior to the drying of which the softening down and wiping out of the brightest points or parts is effected in the manner already described.

The finished picture is varnished for the purpose of increasing the brilliancy of the colours, and in order to prevent soaking in and dulling due to careless drying. Too strong a gloss or lustre is removed by brushing or by means of petroleum.—Ulf Seidl, 9, Weihburg Strasse, Vienna.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sunday, August 28.

Hammersmith Hampshire House P.S. Outing to The Chess Valley.

Tuesday, August 30.

Hackney Phot. Soc. "Garden Flowers." A. C. Fort.
Scottish C.W.S.C.C. (Glasgow). Criticism of Holiday Prints.

Thursday, September 1.

Kinning Park Co-op. Soc. Open Night.
North Middlesex P.S. Competitions: Prints and Slides, General.

Saturday, September 3.

Kinning Park Co-op. Soc. Outing to Fereneze and Gleniffer Braes.
Scottish C.W.S.C.C. (Glasgow). Outing to Langbank.

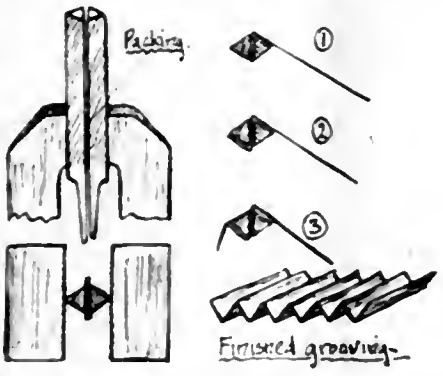
CROYDON CAMERA CLUB.

Out of the trials and tribulations of Mr. J. Walker arose last week a topping tip. It happens that he is possessed of a washing tank and contained corrugated rack. It also happened, indeed it was inevitable, that either the plates were too small for the rack or the rack was too large for the plates, which were of special proportions. So the owner hied himself unto a London dealer of repute and attempted to place an order for a superior rack made to measure. He was courteously informed this was out of the question, as the racks are made by a special machine, and to carry out his wishes a new one would have to be made, and possibly a new factory erected to hold it. Whereupon Mr. Walker returned to Croydon, invoking a Calvinistic version of the "H—— and D—— doctrine" more understandable than the one recently expounded in this journal.

However, there is a practice in the club to consult either "Vivian" or "Rose" when in difficulties of this nature. Mr. V. Jobling happened to be handy and his services were secured. "Why, the thing is as easy as drinking," he observed, and last week, by request, the procedure was explained.

To make the corrugations, either in sheet zinc, tinplate or brass,

two triangular files are taken, and a strip of metal about an inch long, and a little thicker than the metal to be operated upon, is sandwiched between them, as shown in the sketch in side elevation and plan. The files are preferably gripped between the jaws of a vice, or they may be bound together with wire. One end of the strip to be corrugated is inserted between the files and bent over, as indicated at 1. The strip is then reversed between the files and bent as shown at 2. It is again reversed and bent as shown at 3: these operations being repeated until the required length is corrugated. The form of the corrugations (indicated in the sketch) is



better adapted, he said, for securely holding dry-plates than the usual commercial pattern, and any length of metal can be treated speedily and easily.

A convenient way of making a plate rack is to take a strip of metal of the requisite length, remembering to allow for the corrugations, and bend it at the corners to rectangular shape, the corrugations being made where required. It can then be attached to a wooden framework by household brass pins, or soldered, if preferred, to a metal support. Mr Jobling spoke highly of wood for the purpose, provided it is treated with paraffin wax. Some paraffin wax (candles will do well) is kept melted in a shallow metal tray, all sides of the framework being successively immersed until they have absorbed a fair amount of the wax. It was unanimously agreed that the method demonstrated of making plate-racks was extremely neat, and likely to prove useful on many occasions. Divers other matters also received consideration during the evening.

Commercial & Legal Intelligence.

Legal Notices.—The partnership between Ernest Hill and Emil Schou, carrying on business as photographers, enlargers and artists, at 12, Custom House Street, Cardiff, under the style of Hill & Schou, has been dissolved by mutual consent. All debts due to and owing by the late firm will be received and paid by Ernest Hill.

NEW COMPANIES.

D. O. S. Associates, Ltd.—Registered August 17. Capital, £80,000 in £1 shares. Objects: To take over all the shares in the Drawing Office Supplies Ltd. of 51, Cheapside, E.C., and to carry on the business of lithographers, photographers, photo and photo-mechanical plan printers, map and plan mounters, draughtsmen and tracers, manufacturers of and dealers in photographic papers, chemicals, instruments, etc. The first directors are:—W. Monkhouse, 10, Augustus Road, Wimbledon Park, S.W.19; B. J. Hall, Fieldens, Eastcote, Middlesex, and J. S. Walker, 64, Sellons Avenue, Harlesden, N.W.10. Private company.

A Houghton Clearance List.—Messrs. Houghtons have just issued a 12-page list of clearance bargains in mounts, albums, and photographic accessories, chief among which are a great variety of plate and print washers, commercial teak developing tanks, and printing frames and negative boxes. The list is sent free on application.

News and Notes.

Lost Rollex Camera.—Messrs. Robbins, Manistre and Co., 2, Poultry, Cheapside, London, E.C.2, ask us to mention that the loser of a quarter-plate Rollex camera (N. and G. Sibyl pattern), fitted with Zeiss lens, may be able to recover his apparatus if he will communicate with them. Description of the camera and serial number of the lens should, if possible, be stated.

Picture Postcards and Postal Rates.—The regulation as to the five words of greeting allowed on a postcard for a penny, instead of the full rate of 1½d., will not be altered. But early next year the Postmaster-General believes that the financial situation of the Post Office will be bettered, so that the extra rates on cards and letters now imposed may then be taken off.

Messrs. Dallmeyer inform us that the cinematograph film obtained of the Carpentier v. Dempsey fight was taken with one of their No. 12 cinematograph lenses having an equivalent focal-length of 17 ins., and working at the aperture of *f*/5.6, requiring a back extension of only 8½ ins. This lens is identical with the No. 4 Ser. VI. Dallon tele-photo lenses, which are listed for use on half-plate cameras.

Death of Mrs. E. J. Humphery.—We are exceedingly sorry to hear of the death, on Saturday last, August 20, of Mrs. E. J. Humphery. With her husband, Mrs. Humphery regularly took part in the meetings of the Photographic Convention, and was greatly esteemed by those attending these annual gatherings. Conventioners will, we are sure, join with us in extending sympathy to Mr Humphery in his bereavement.

Messrs. Houghtons, in the current issue of the "Ensign Messenger," publish some reproductions of the enlargements which won prizes ranging from £50 in the Ensign enlargement competition. Particulars are also given of the £100 competition for photographs on "Ensign" film. A new size of camera is announced, namely, the No. 4 "Popular Ensign Klito," for 8 × 12 cm. plates. This is the size recommended by the British Photographic Manufacturers' Association to replace the quarter-plate in course of time.

Seltona Demonstrations.—The Leto Co. inform us that the popular Seltona demonstration sets will be issued from the commencement of October to the end of April. Club secretaries wishing to arrange for an interesting evening during their winter session should write to the firm (Roman Wall House, London, E.C.3) for full particulars. The lecturette issued with the demonstration set enables a member to act as lecturer, but it is advisable for club secretaries when writing to mention the proposed date and approximate number expected to be present.

Sales Development.—In the current issue of "System" is an article, "Making More Sales for Manufacturer and Retailer," by Mr R. Crane, advertisement manager of Messrs. W. Butcher and Son. Mr Crane dwells upon the help organised by Messrs. Butcher for the sale of goods by retailers in the shape of showcards and window displays, catalogues for retail customers, and is able to show the beneficial effect of these measures. In the same issue is a paper by Mr. S. W. Copley who writes on his experience in banking and assurance. Among the many interests which Mr. Copley has in business is that of the photographic firm of Photex Papers, Ltd.

Care of Old Furniture.—Many of the studios owned by our best and well-known workers being furnished with genuine old chests and other artistic articles of value, it is deserving of note that such pieces are liable to suffer from cracking during excessively hot weather. Mr. Oliver Brackett, of the department of woodwork at the Victoria and Albert Museum, after consulting with expert workmen who have the furniture in the Museum under constant care, agreed that the recent heat has not been particularly favourable for old "pieces." "So far as this museum is concerned," he explained to a "Daily Chronicle" reporter, "we do not note any particular effect on the furniture. But, then this building has particularly thick walls, which would not be found in the majority of private houses, and fans are kept constantly in motion, so that the temperature may be regulated as desired. But even so, there is always anxiety attached to the care of Boule and other inlaid work. Variations in temperature are at once reflected in the condition of this type of furniture into the making of which glue enters so largely." Asked for suggestions for collectors who are anxious about their treasures, Mr. Brackett advised the use of beeswax and turpentine, except for veneered and

polished woods, which should be wiped over with an oiled rag. Cracks are due to the heat extracting from the wood any moisture which it holds. Fissures should be filled and glue replaced where necessary.

IDEAL HOMES EXHIBITION.—In the photographic section of this exhibition, which opens at Glasgow on September 19 next, the judges will be Messrs. J. Craig Annan of Glasgow, Arch. Cochrane of Barrhead, and Professor D. Forrester Wilson of the Glasgow School of Art. Exhibits are accepted in five classes, allotted respectively to landscape and seascape, portraiture and figure studies, architecture, contact prints of any subjects, and prints illustrating a happy holiday. Prizes ranging from £10 10s. are awarded in each of these classes. The entry form must reach the General Manager of the Exhibition, Kelvin Hall, Glasgow, not later than Thursday, September 8, and exhibits must be despatched to arrive on the same day.

MESSRS. F. BRODRICK, LTD., who for some years past have been in business in High Street, Bloomsbury, as manufacturers of tanks, printing machines, and many other photographic accessories, have recently built and equipped a factory in the outskirts of South-West London, adequate for the increased demand for their goods. We recently had the pleasure of visiting this factory at the time when Messrs. Brodrick were completing apparatus in the shape of tanks, boxes, and other accessories for the Shackleton expedition. It was evident that the equipment of wood-working machinery provides ample facilities for the making of the many pieces of photographers' outfits, which hitherto have been staple products of the firm, *e.g.*, printing cabinets, enlarging easels, drying cupboards and racks, and hard wood tanks for development, fixing, etc., in a wide range of sizes. Moreover, the larger accommodation gives Messrs. Brodrick greater scope for their business in the complete building and furnishing of studios, design and supply of exhibition stands, etc., a department which of late has become of increased importance. The factory is staffed throughout with ex-Service men, and Messrs. Brodrick may be congratulated upon their enterprise in having fitted up a factory which will enable them to keep pace with the demand for their goods.

KODAK, LTD., DISCONTINUE DRY-PLATE MANUFACTURE.—A sensational announcement is made by Messrs. Kodak, Ltd., on an advertisement page of this issue to the effect that they have discontinued the manufacture of gelatine dry plates. The department of the Harrow Works, hitherto employed for the manufacture of plates, has been converted to the making of Eastman Portrait Film and the other grades of sensitive cut film. The firm's dry plates will disappear from the market. The step is a significant one in the manufacturing policy of the Kodak Company; and its significance becomes more striking when it is remembered that the immense business of the Company began with the manufacture of dry plates upon a very small scale, by Mr. George Eastman, no longer ago than the year 1880. Nine years later the Eastman transparent roll-film was placed on the market; and since then the Kodak Company has never looked back in its production of flexible sensitive material, an immense demand for which has been created by the rapid rise of the cinematograph industry. By now cutting itself adrift from the manufacture of dry plates, Messrs. Kodak, Ltd., no doubt, wish to signify, as no other act could do, their profound confidence in a stiff celluloid film as a sensitive material superior to dry plates for all the ordinary purposes of photography. Putting aside quality of emulsion, the lightness, unbreakability and facility of cutting any piece of film to a required size are positive advantages, which have been not unduly emphasised in their advertisement programme of Eastman Portrait Film. The step of discontinuing the manufacture of dry plates is, of course, a logical outcome of confidence in the qualities of Portrait Film, and would scarcely have been taken were it not felt that the company will benefit by staking this department of its trade upon those qualities. Nevertheless, we cannot help thinking that this Cortes-like policy will come as a surprise to many users of the dry plates hitherto made by the Company. It must be presumed that the deliberate resignation of a certain amount of trade in dry plates is to be interpreted as a sign of the company's belief in the wisdom of concentrating its manufacture upon Portrait Film.

PHOTOGRAPHING THE AURORA BOREALIS.—In the "Scientific American Monthly" for July last appears reproductions of a remarkable series of photographs of the aurora borealis taken by Prof. Carl Stormer, of Christiania, who, in an interesting article describing them, says that in March of last year there appeared over the greater part of the earth a display of northern lights, the form and beauty of colouring of which were unique, and which aroused the keenest attention among all investigators. This display appeared in great splendour in Europe, where it was observed by the professor and his assistants from a number of stations in Southern Norway. These stations were connected with each other by telephone, and provided with cameras so that many hundred successful photographs were taken in the course of the night. As they were taken simultaneously at several stations, the height and situation of the northern lights can be calculated with accuracy. It appeared that on that night the rays of the northern lights reached quite exceptional heights, between 500 and 600 km. above the earth. As all usual observations of the northern lights are more or less subjective and unreliable, it is of the greatest importance to obtain an objective method, and the only reliable one is in the present case photographic. For many years the problem of photographing the northern lights resisted all efforts. It was not until 1892 that Brendel succeeded in obtaining a fairly serviceable picture by an exposure of seven seconds during a stay at Bossekop in the north of Norway. More pictures with short exposures were not published, until in 1909, when Prof. Stormer commenced systematic investigations in order to solve the problem. By the use of a small cinematograph lens with a 25 mm. aperture and a focal length of 50 mm. and Lumière violet label plates, he succeeded in obtaining serviceable pictures with exposures of a few seconds, and in consequence he undertook two northern lights expeditions in 1910 and 1913 to Bossekop, in order to apply photography to the study and measurement of altitude of the northern lights. Bossekop, 80 kilometres south of Hammerfest, is a classical spot for the investigation of the northern lights, and in the course of time has been visited by many scientists. One of the pictures in the article shows one of the cameras used on the expedition of 1913. Fitted to it is an arrangement whereby the image of an illuminated watch can be photographed on the plate simultaneously with the northern lights. It was thereby possible to read the time direct on the plate, and it was unnecessary to take time observations during the work. This arrangement was particularly useful when the northern lights developed in great beauty. The pictures could then be taken quickly one after the other with registration of time for each picture. A cinematograph was also employed and the operator obtained series in which each picture was illuminated for about four seconds.

AMERICA'S FIRST "MOVIE SHOW."

To the Editors.

Gentlemen,—Referring to the letter of J. W. Dickerson, on page 455 of your issue of July 29, in *re* C. Francis Jenkins and the beginnings of motion picture photography in America, may I point out that all the information given in "The New York Tribune" and "The Literary Digest," to which Mr. Dickerson refers, with further particulars and illustrations, can be found on pages 37-54 of Homer Croy's "How Motion Pictures are Made," published by Harper and Brothers, New York, 1918.

Another reference to Jenkins and his "Phantascope" may be found in that entertaining brochure, "The Story of the Motion Picture, 65 B.C. to 1920 A.D.," by Ben J. Lubschez, New York, 1920, this Lubschez, by the way, being a brother of N. E. Luboshez, who so often enlivens the meetings of your photographic societies.

A portrait of Jenkins, with illustrations of his motion-picture apparatus, may be seen in his book, "Picture Ribbons: An Exposition of the Methods and Apparatus Employed in the Manufacture of the Picture Ribbons Used in Projecting Lanterns to Give the Appearance of Objects in Motion," published by the author at Washington, D.C., in 1897. See also many references in Appendix II., years 1894-1898, in "Living Pictures," by Hopwood and Foster, London, 1915.—Yours faithfully,

JOHN A. TENNANT,
Editor of "The Photo-Miniature."

103, Park Avenue, New York.
August 12, 1921.

THE LATITUDE AND DEVELOPMENT OF DRY PLATES.

To the Editors.

Gentlemen,—The latitude of most modern plates (I have experimented with five different makes) is truly remarkable, the word "latitude" being defined, of course, as "the range of length of exposure which may be given to a plate under any given conditions of stop and subject to produce a good negative." Experimenters, as a rule, devote their attention to the remedying of over-exposure, or, rather, to the point to which one may over-expose, yet get a really good print from the overdone negative.

My own rather rough experiments were with plates of what one may term average over-exposure, such as any practical worker may meet with. I saw no object in purposely over-exposing enormously and then, in some special way, getting the best printable negatives possible from such exposures. It was everyday work I had in mind, and in everyday work one does not over-expose "enormously." An over-exposure of three or four times is, I think, all an average worker makes accidentally, and although I have in front of me passable—I may even say good—results from plates over-exposed twenty to thirty times, I do not consider them to be of much interest to practical workers, except, of course, as curiosities. Such exposures were known over-exposures, and were treated as such in developing, a process differing materially from that of the treatment of unknown over-exposures, since most of us are not aware of over-timing until the developer starts its work.

My principal experiments were carried out with five different makes of plates, having speeds of between 260 and 350 H & D, medium speeds, such as I believe the average worker uses. The accurate exposures given were the result of many years' experience, such exposures being endorsed by three exposure meters, and when there were differences—as there were at times—between the readings of the meters, the mean was taken. The subjects, it may be said, were a still-life set-piece and an architectural subject opposite my place of business, the camera being set in an upper window during the July spell of cloudless days, when the light at midday was as constant as it could possibly be in England.

I found that I might over-expose six times, and by using a normal developer, could get negatives which gave perfect prints on self-toning paper, and that by altering the developer to suit the extent of over-exposure, I could get really good printable negatives from plates over-exposed as much as eighteen times. To my way of thinking, the task of over-exposing enormously and making up the developer to counteract the over-exposures, is one for the laboratory alone, whereas that of getting the best negative from an unknown over-exposure when using a normal developer is one all average workers may have put before them, and it is interesting to know what can be done under such circumstances. A studio or out-of-doors operator must be very inexperienced to so misjudge light or subject as to over-expose more than six times, though I have known experienced workers to do it by calculating an exposure for a small stop and forgetting to insert it, thus using the lens in error at its largest (and focussing) aperture.

Present-day methods of developing a plate found to be over-exposed, I believe, vary considerably, but in days gone by it was the custom to add a good dose of bromide, or to increase the amount of the density-giver, usually labelled "No. 1," the "No. 2" solution being the accelerator. Increase of the density-giver after the developer has started work may have some beneficial effect, but the practice of adding bromide after development has started was abandoned long ago by expert workers, because it was proved to have no effect.

The secret of taking advantage of the great latitude of modern plates, and of success in developing over-exposures up to six times, is to use a normal developer with the average amount of bromide, ignore any sign of over-exposure and the appearance of the image, and develop for the same time as one would develop a correctly-exposed plate, thus throwing factorial development overboard for exposures other than the correct one, and adopting tank development—in theory, if not actually in practice. Tank development is unquestionably the best for all under- and over-exposed negatives, and although I rarely use a tank, I always use the system, but employ a dish.

There can be a no better or no more instructive experiment than to expose four or more quarter-plates for varying times beyond the normal, and to develop them all at one time in the same dish, along with a correctly-exposed plate, keeping an eye on the latter and ignoring the others. The finished negatives will, of course, vary in appearance and density very considerably, but they should, if properly printed, give good results—so good that it would be a very difficult matter for the uninitiated to tell the prints from the over-exposed plates from that correctly exposed.

If negatives less dense and of a more even appearance—but of little or no better printing quality—are wanted, then altering the composition of the developer to suit over-exposures will give them, but in order to secure the best results the approximate amount of over-exposure should be known. Assuming a normal two-solution pyro-soda developer is used, over-exposures up to four times may be counteracted by using equal parts (normal developer) and adding bromide (before applying the developer) up to, say, four drops of a 10 per cent. solution to each ounce of working solution, but for over-exposures above four times, which should be rare in everyday work, one must start increasing the density giver (No. 1) as well as the bromide. This increase goes on as the exposure increases, and I have found that for a known over-exposure of twenty times a developer consisting of 2 ozs. of No. 1 and 1 oz. of No. 2, with 15 drops of a 10 per cent. bromide, to give a good negative. This particular work, however, is beyond the scope of the present note.

The work I set out to do was to find out how far one could take advantage of the great latitude of modern plates without altering one's developer and method of working. In conclusion, I may say that for the very dense negatives one gets from over-exposed plates developed in the manner I have advocated, I find nothing better than ordinary and self-toning paper—I use Ilford and Wellington's respectively, though others may be quite as good.

L. Tennant Woods.

THE PHOTOGRAPHIC CANVASSING FRAUD AT CANTERBURY.

To the Editors.

Gentlemen,—The photographic profession in general owe to the Chief Constable of Canterbury, Mr. Carlton, a deep debt of gratitude for his having brought yet another photographic fraud to book in Canterbury, and the gentlemen sitting on the Bench are to be congratulated on taking the serious view of these frauds they did in passing sentence. It is only by doing so, that this sort of thing will stop, and the case should be well published.

This free enlargement and colouring stunt has been carried on for years, to the detriment not only of the photographic profession, but to the annoyance and loss of the general public. One looks back to the time of war, when so many people were left perhaps with one photograph only of the departed and much-loved one, and perhaps would not part with it for untold gold. These canvassing frauds collect such photographs with a plausible tale of what they are willing to do for nothing or little, so that many, on the spur of the moment, part with their much-cherished photograph, to find at a later date they can only get it back by paying 15s. 6d. for a 3s. frame; or, worse still, having paid a deposit, find they hear no more about it. The valuable photograph, which they are unable to replace, has been lost for ever.

It is quite evident that the Chief of Police of Canterbury is a very practical business man, and while he does not make too much of the few shillings collected as deposits, he has taken up the position of how cruel it is to rob people of their photographs in this way, and at a time so soon after a great war. He thus kills two birds with one stone—helps the photographer and opens the eyes of the public to the danger of parting with valuable photographs to strangers. Might I suggest that when photographers do get a Chief of Police to bring these frauds to book, a suitable letter of thanks should be personally addressed to the gentleman who goes to the trouble of taking the matter up, and a further letter should be addressed to the Chairman of the Watch Committee. This would prevent the matter dropping, and bring the public's notice to the fact that it is necessary to stop this canvassing fraud. The public then would not be so eager to believe all that is told them about something for nothing and the opening of premises. It would also induce other Chiefs of Police to take the same trouble as Mr. Carlton has in this matter.—Yours faithfully,

An Old Photographer.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. D. M.—The alkali of developers has a considerable corrosive action on zinc, and this metal has a comparatively short life as a lining for developing tanks. These tanks are better lined with sheet lead, or without any metal lining if well made of hard wood.

F. T.—Of the three designs, we prefer the simplest, No. 21A. In No. 21B light is lost by recessing the sky-light into the roof, and in No. 21 there is increased cost of construction with no compensating advantage. We should recommend a rather longer run of glass, say 17 ft., instead of only 15 ft.

W. Harpur.—Your friend is not quite right. You can use supplementary lenses on the lens of a reflex camera, although there is not the same advantage in using them as there is with an ordinary fixed-focus camera, since you can take a standpoint close to the subject and focus correctly by extending the camera to the required amount.

A. C. W.—(1) Many local periodicals would only pay a reproduction fee of 5s., or even less. (2) It is a case usually (unless the photograph is of special local interest) of getting what you can instead of charging what you should. In many cases the subdivision of the whole edition under different titles does not represent a very large circulation, and very frequently a fee less than the common one of 10s. 6d. is paid for the whole lot of the localised editions.

H. J. C.—Probably what is known as "Silver point" is referred to. In this method of drawing a point or pencil of silver is used upon what is called "metallic" card or paper on which the silver makes a very fine or delicate line. It is an art little practised, as few artists can draw with the firmness, delicacy, and accuracy necessary, as erasure or correction is impossible. We do not know of any brand of bromide paper on a vellum paper base. You could use Kodak Transferotype and transfer the gelatine film to any paper you choose.

E G.—The numbers that you quote, *f*/6.8, etc., are the F. Nos. of the lens, the exposure required with the different stops being proportional to the squares of these Nos.; that is to say, if you require 1 sec. at *f*/6.8, the exposure with *f*/9 will be 1 sec. x 9 x 9 ÷ 6.8 ÷ 6.8.

The corresponding U.S. Nos. are:—

f/6.8	*f*/9	*f*/12.5	*f*/18	*f*/25	*f*/36
3	5	9	20	36	80

In the case of the U.S. No., of course, the exposures are directly proportional to the Nos.; that is to say, exposure with stop No. 9 is one-quarter that with stop No. 36.

S. E.—A bleacher which is not so poisonous is the following:—

Thiocarbamide	240 grs.	25 gms.
Nitric acid	4 drs. (fl)	25 c.c.s.
Water	20 ozs.	1,000 c.c.s.

We suppose your difficulty is to buy the very poisonous cyanide. If you could buy mercury bichloride, as used for intensification, you would find this just as effective as cyanide and iodine, but we think you will find the thiocarbamide sufficient for the purpose, though you will probably have to write to Hopkins & Williams, 16, Cross Street, Hatton Garden, E.C.1, or British Drug Houses, Ltd., 22-30, Graham Street, City Road, N.1, in order to get it.

W. P. H.—The plates ought not to frill as badly as you describe. If the temperature is never above 75 deg. we should not have thought it was necessary to use the tropical hardener. Perhaps the cause of the frilling lies in the use of baths at different temperatures, or perhaps more likely, washing between development and fixing. We think that very likely if you were to use an acid hardening fixing bath, made up with alum, sulphite and hypo, and were to put the plates straight from the developer into this without any washing, you would find your frilling troubles disappear, particularly if you can keep all solutions at an even temperature of, say, 70 deg., testing this with a thermometer.

A. G.—You will not find five 1,000-c.p. lamps too much if you wish to give short exposures. The light from these, being spread over a larger area, will not require so much diffusion as was necessary with a single 3,000-c.p. lamp. If you use rapid Iso plates, 500 H. & D., you should not have to give more than 1 sec. at *f*/4. Of course, the distance between lamps and sitter has a great effect on the exposure. You will find it satisfactory to fix three lamps for the front light and two for the side, beginning opposite the centre of the background. If possible arrange to have the lamps to raise and lower. It is necessary to have them 8 ft. from the floor for standing figures and groups, but 6 ft. is high enough for most sitting figures and children. Roughly speaking, the light should fall on the sitter's head at an angle of 45 deg. Thin calico or nainsook makes a good diffuser.

Right to Photograph.—(1) If I take a photograph of, say, children playing on the sands and subsequently sell the photograph to a firm for advertising purposes, can the parents of the children take any action to stop the publishing of the same as an advertisement, either against me or the firm using the photograph? (2) Suppose I sell a firm a photograph of my own children for use in their advertising business, am I able to take other photographs of the same children and submit such photographs to another firm for their advertising department, without infringing my contract with the first firm? Actual contract with first firm: To supply them with a separate photograph of each child for a stated fee.—L. S.

(1) In this country the "right of privacy," which is what the subject of your query amounts to, is sustainable very seldom. Unless the photograph is libellous in character, holding persons up to ridicule or contempt, it is not possible to restrain anyone from making any use they like of portraits taken unawares. This is a rather complicated question, and involves certain legal obscurities, as you may see by referring to the article on it in the "B.J." of last year, August 27, page 525. (2) This question also is a somewhat obscure one, and in your case contract relations appear to be mixed up with the question of copyright. Generally it is assumed that you can create copyright in a photograph of the same subject repeated, with variations, several times, but we think that is a rather dangerous assumption, and in your circumstances we should think it very likely, in view of your contract, that the advertising firm would have a case against you on the ground of breach of contract. See "B.J." May 14 1920, page 294.

Contents.

SUMMARY.

Dr. B. T. J. Glover, in the second portion of his paper advocating a factorial system of developing bromide prints, sets forth the observations on which his recommendations are based, and shows that by adoption of a factorial method both the best exposure for the bromide paper and the best period of development may be ascertained, or, perhaps we should say, these two times brought into correct relation. (P. 519.)

In a leading article we deal with the provision of interchangeable fitments for the lenses and plate-holders of various cameras whereby considerable economy may be effected, not only in the time required for changing from one lens to another, but in the outfit which is necessary when employing different sizes of camera. (P. 518.)

In the further portion of the paper on the theory and technique of light-filters, M. G. V. Potapenko gives the specifications of different types of light-filter, and shows the relation of a filter consisting of several dyes to the properties of the individual components. (P. 522.)

A highly successful Convention of the Photographers' Association of the Pacific North-West was recently held at Vancouver, B.C. (P. 625.)

The estate of the late Mr. S. H. Fry, formerly secretary of the Professional Photographers' Association, has been proved at over £12,000. (P. 524.)

Change of colour in studio blinds, by exposure to light, may be the cause of misjudgment of the strength of illumination. (P. 518.)

In photographing large groups in the studio, the difficulty of obtaining even illumination may be reduced by the use of a large white background as reflector and by closing the blinds at the end of the studio where the group is arranged. (P. 517.)

Formulæ for preparing clear collodoid solution from waste film are given by correspondents of the "Pharmaceutical Journal." (P. 526.)

The death is reported of Mr. Peter Cooper Hewitt, inventor of the well-known lamp known by his name. (P. 526.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. E. A. Burchardt raises a point in connection with the making of sets of three-colour negatives from Autochrome transparencies. From his observations in making reproductions of sharply outlined colour charts, he concludes it is necessary to back up the Autochrome with a very thin negative made by white light. (P. 33.)

Mr. F. J. Wall concludes his review of processes for obtaining gelatine reliefs (for use in the assemblage processes of colour printing) by methods other than that of exposing bichromated colloid films to light. (P. 34.)

A two-colour process of cinematography is described in a patent specification, one of the authors of which is the late Mr. W. Friese-Greene. (P. 36.)

EX CATHEDRA.

Groups in the Studio. One of the greatest difficulties encountered in making large groups in an ordinary studio is that of obtaining even illumination of all the figures. This can be minimised by closing the curtains or blinds at the end of the studio where the group is posed and admitting as much light as possible from the other end, taking care to open the blinds right up to the top. This will give a high front light, which is what is wanted. Another aid is to use a large white background as a reflector. This should be placed about midway between the figures and the camera and slightly turned to throw the light upon the shadow side. Care must be taken not to include the edge of this reflector upon the negative. If the light will allow it, a rather small stop should be used in preference to swinging the camera back, as the latter procedure has a tendency to destroy the proper proportions of the various rows. If it can be managed, the best results are to be obtained by working at a slight angle across the studio, the camera being nearer the glass side. Full exposures should be given with large studio groups, so that the back row of figures can be fully developed before the front row is too dense.

* * *

System in Bromide Printing. The paper by Dr. B. T. J. Glover, of which the second part appears on another page of this issue, is deserving of a careful reading, since it is an endeavour to substitute a system based on scientific principles for rule-of-thumb methods in one of the most largely practised of photographic operations, viz., the making of prints and enlargements on bromide papers. That such a system is a desideratum was impressed upon us a day or two ago by the remark of a well-known teacher of photography to the effect that he was bound to tell his students of bromide printing that he could add nothing material to the instructions given by the makers of the papers. That is an admission that the difference between a maker of best bromide prints and the maker of indifferent ones consists in the possession of a certain skill, technique, *flair*—call it what you like—something that cannot be communicated from one person to another in definite terms. To the reform of that admittedly unsatisfactory state of things comes Dr. Glover with certain definite rules based on observations on the relation between the exposure and the time of development of bromide prints. Of these, the most challenging is that, within certain limits of time of development, that is above a minimum and below a maximum, as Dr. Glover defines these times, the product of the time of exposure and time of (correct) development is a constant. We think that more data and confirmation by other workers are required before accepting this formula, but it is relevant to add that a formula which falls short of scientific exactitude

may easily be exact enough for application with benefit to a process like bromide printing. A formula may fit working conditions sufficiently well to be of value in them—and that, we imagine, is all that Dr. Glover claims for his. Granting these preliminaries, the very simple rule for the factorial development of bromide prints, and also for the establishment of a correct time of exposure, follows, as set forth in the paper, and certainly is a system of a kind which has hitherto been lacking as a substitute for the eye in securing the best results of which the process is capable and in repeating them with uniformity.

* * *

Studio Blinds. Those portrait photographers who favour the convenient "festoon" curtains for controlling the light will do well to purchase only such fabrics as will stand prolonged exposure to light without fading. Many of the dark green and blue sateens and casement cloths lose much of their light-stopping power after exposure for a single season, but with these the effect on the lighting is visible and can be allowed for. We recently visited a studio where the conditions were, perhaps, rather unusual, the aspect being westerly and the dark curtains originally a deep brown. They have now faded to such an extent that a large quantity of orange-coloured light passes through, and even when the glass is entirely covered, the studio appears to be quite well illuminated. This, of course, makes it very difficult to judge any particular effect of light, as the orange, though visually luminous, has little effect upon the plate. The best material for the purpose which we have seen is black Bolton sheeting, which is quite opaque, and appears to remain so for several years.

LENS AND CAMERA FITTINGS.

It is hardly going too far to assert that a very large proportion of photographers fail to obtain the greatest amount of service from a fairly large collection of apparatus through lack of any means of securing interchangeability between the components of the various cameras they possess. Many years ago Messrs. Ross made the first step in this direction, when they issued their series of portable symmetrical lenses, the first ten sizes of which, having a range of focal lengths from three to fifteen inches, fitted the same flange. Later, the introduction of the R.P.S. standard flanges did much to remove the inconvenience of having several lenses of nearly the same size, each requiring a separate flange and front, because the screw threads differed slightly in pitch or diameter. To obtain the full advantage of the standard flanges it is necessary to take stock of all lenses up to a certain size, which can be used upon any particular camera, and to fit a front panel with a standard flange which will accommodate the largest of them, and to provide each of the smaller ones with a brass adapter of the correct size. Most opticians and some of the repairing firms will make such adapters for a very few shillings, and the time saved and the advantage of being able to transfer a lens without removing a flange and making even a rough front board will amply justify the expenditure. Another way of gaining the same end is to have a number of small standard-sized front panels carrying the original flanges, and to make another panel to fit each camera with a central recess to receive them. For example, to take an actual case, the standard panels fit a half-plate Premo camera and carry four lenses of from 3 to 12 inches focal length, besides an Adon. These can in a moment be transferred to whole plate and 12 x 10 cameras without any unscrewing being necessary. They also fit a copying camera and an enlarging lantern, in both of which short-focus lenses are often badly needed.

Coming to the camera, the same idea can be carried out with regard to dark slides and inner carriers. It is not uncommon to find two outdoor cameras of the same size of which the slides are of a different gauge and register, so that only, say, three slides can be taken on an outdoor job, when six might be used without the inconvenience of changing. As a rule, the adjustment can be done quite easily, the slides being either planed down or built up as necessary, and the runners on the reversing back shifted to fit. The next step is to make adapting frames to carry the reversing frames of the smaller cameras in the back of the larger one, thus utilising half- or whole-plate slides in a 12 x 10 camera. This will often save carrying a second set of apparatus, if worked in conjunction with the interchangeable lens system described above. A half-plate roll holder or film-pack adapter fitted in the same way affords a convenient means of carrying a reserve of exposures, which may possibly produce a larger return than the original order amounts to, an actual case being that of a photographer who, on a visit to take 12 x 10 architectural negatives, was asked if he could take some prize animals which were being sold the next morning. Thanks to his film outfit, he was able to do so, and netted a goodly order. It may be worth mentioning that to cope with an emergency order of this nature a 12 x 10 plate may be made to yield four 6 x 5 negatives by using a simple card or zinc mask which only allows one-fourth of the plate to be exposed at once. If the camera be provided with ample rising and cross front adjustment and a good lens the pictures can be sufficiently well centred. In like manner a stereoscopic negative can be made by using a card which will cover each half of the plate in succession and moving the cross front to centre the lens upon each as nearly as possible. Inner carriers and film carriers should all fit and register in every slide, and in any larger carrier in which it is desirable to use them. Some slides have metal corners to prevent the shutters from pulling out, while others have screws through the wood for the same purpose. If all carriers are grooved to allow the screws to pass, they can be used in either pattern of slide.

The studio camera is usually a complete item, but its usefulness can occasionally be increased by the addition of either a back or front extension. The tendency is towards the use of lenses of greater focal length, and the expense of a new camera to accommodate them may be avoided by the addition of a front extension, which may take the form of a light box fitted to an extra front panel. If this can be made to reverse it will allow of the use of a short-focus lens for making a very small picture or a greatly-reduced copy. An extension can be fitted at the rear of the camera, but is liable to interfere with the action of the swing-back. If a front extension is to be used for copying, it may advantageously be of conical form, as it is then less likely to interfere with the illumination of the original.

A very useful fitment for the studio camera is a bellows or sliding box fitted in front of the lens to carry a negative or transparency for enlarging or reducing direct upon bromide paper or when making enlarged negatives. This may conveniently be marked for different degrees of enlargement with one or more lenses, and then the required enlargement can easily be obtained by adjusting the rear of the camera.

It is, perhaps, hardly necessary to point out that all outdoor cameras should be fitted for the standard ¼-inch

Whitworth tripod screw, as not only can they be used with any tripod, but in the case of the screw being lost a "bolt" of this size can be procured for two or three pence from any village ironmonger or blacksmith. A long screw with a flynut is preferable to the usual T pattern, as it enables the camera to be fitted to the top of a pair of steps, or at the end of a plank for awkward jobs.

THE CASE FOR FACTORIAL DEVELOPMENT OF BROMIDE PAPER.

(*Concluded from page 504.*)

Exposure and Development Properties of Bromide Paper.

The exposure and development properties of bromide paper which will be dealt with in the succeeding paragraphs are restricted to those which have a definite bearing upon the problem of formulating rules to take the place of "development by inspection."

Various kinds of printing paper exhibit different powers of recording black. Other things being equal, the blacker the black that the paper can be made to record the better. Prominent workers use platinum paper, carbon paper, and work in ink (Bromoil, etc.), partly because of the ease with which they can get an intense black if they wish. The best black that a paper will yield is called its "maximum black." Let us examine the parts played by exposure and development respectively in the production of the best black possible on some particular brand of bromide paper. It is a matter of simple experiment, and is more or less common knowledge, that increase of exposure gives rise to increasing darkness of tone. Before black can be obtained, therefore, a sufficient exposure is required. More exposure than this will not yield a deeper black, and less exposure yields a dark grey or, at any rate, a less deep black. But it is not so generally known that unless development be carried *beyond* a certain minimum degree a very great increase in exposure is needed to record the best black (maximum black) compared with the exposure required when development for a proper time is utilised.

The following experiment illustrates this development property:—It was in the first place ascertained that under the temperature and development conditions which prevailed the minimum development time for maximum black, equivalent to the minimum development time for the gamma infinity of the paper, was approximately 70 secs. This time was deduced from the paper curves in which the reflection densities of the paper were plotted against the logarithm of the light intensities which gave rise to them. It was ascertained that with the particular printing light employed 16 seconds exposure and 70 seconds development yielded a black whose measurement was 1.50 (D_R), equal to the maximum black of this paper. Let us see whether increase in exposure will allow this black to be obtained in 35 seconds development. Sixty-four seconds exposure and 35 seconds development yielded D_R = 1.40. 256 seconds exposure and 35 seconds development yielded D_R = 1.425. Both of them were blacks of a bad colour. It is evident that 16 times the normal exposure fails to bring out black when only half the minimum time of development is employed.

Prints A and E in Tables I and II illustrate the same failure to record maximum black through insufficient development. Given sufficient exposure, there is a minimum time of development below which the paper fails to yield its best black. The attainment of maximum black coincides with the attainment of the maximum contrast of the paper.[1] The first rule we can formulate is therefore:—

"Development must not be for a shorter time than that required to produce the maximum black of the paper."

This rule must not be understood to imply that every print produced should exhibit black. It means that if the exposure given in printing be sufficient to produce black then the development must be sufficiently prolonged to allow of its attainment.

It is known that in the production of any bromide print there are two variables to be taken into account, one exposure and the other development. If they are completely independent of one another, then it will be necessary to calculate both, if print-making by rule is to be made possible. If, on the other hand, it can be shown that exposure and development are closely related and dependent upon one another, then the calculation of either of them alone will be sufficient.

In Table II details are given of four prints made from a step plate of eleven densities. Each print was developed in fresh Amidol of the Kodak formula at 62 deg. F. The printing distance and printing light were the same in each instance, so that it suffices to express the exposure in seconds in the manner usual with ordinary practical printing. It will be noticed that in each case the exposure given multiplied by the time of development in seconds = 1,800, that is to say, exposure × time of development = constant, or the exposure is inversely proportional to the time of development. The reflection densities (D_R) of each print were measured, and are given in columns E to H.

TABLE II.

	Print ..	E	F	G	H
Densities of the Step Plate. D_R	Exposure in seconds	45	30	15	10
	Total time of development in seconds	40	60	120	180
2.150	Reflection Densities.	.02	.025	.025	.025
2.025		.05	.05	.025	.05
1.875		.10	.075	.075	.075
1.725		.25	.175	.15	.25
1.350		.55	.45	.45	.475
1.075		.80	.75	.80	.80
.880		.975	.975	1.025	1.075
.725		1.125	1.125	1.175	1.375
.525		1.20	1.23	1.44	1.44
.225		1.30	1.35	1.475	1.475
.015		1.325	1.475	1.475	1.475
	Time of first appearance of image in seconds	5	6	8	8
	Watkins' factor	8	10	15	22½
	Fog strip density	.00	.00	00	.00

There is remarkable similarity in appearance in the case of prints F, G and H. Shown to an experienced photographer, he had difficulty in pointing out differences, except upon the closest critical inspection. Had they been pictorial prints they would have been quite indistinguishable. What differences there are can be seen from the figures giving the measured print densities (Table II). In practical photography prints F, G and H would be regarded as the same. It will be noticed that print F had 30 seconds exposure, and

1. "The Sensitometry of Photographic Papers." "B.J.," January 1, 8, and 15, 1915, Messrs. Mees, Nutting and Jones.

print H had 10 seconds exposure. The print with the short exposure was developed for a long time, and compelled to become as dark as print F. Prolonged development has compensated more or less exactly for short exposure. Within the range of exposures from print F to print H (30 seconds to 10 seconds) appropriate development has produced similar prints. The time of appropriate development is that which, when multiplied by the exposure, yields a constant. In print F, 30 seconds exposure × 60 seconds development = 1,800, in print G 15 seconds exposure × 120 seconds development = 1,800, and in print H 10 seconds exposure × 180 seconds = 1,800. The experiment is simple, and can be readily verified. Now let us examine print E. Here we gave 45 seconds exposure and 40 seconds development, again yielding a product upon multiplication of 1,800. But in this case 40 seconds development is insufficient to give the maximum black of the paper, yielding 1.325 instead of 1.475 (see Rule I). We have developed for less than the minimum time of development allowable. This print is also of poor colour compared with the other three. Print E is, in fact, developed to a Watkins factor of 8. With the Kodak formula for Amidol this is not sufficient, a conclusion similarly noted above apropos of Table I. By prints F, G and H we have established the fact that exposure and development are variables which are dependent upon one another. They show that exposure and development are inversely proportional when prints of similar depth are made from the same negative. In any scheme for making prints by rule it will therefore be unnecessary to calculate both exposure *and* development, it will only be necessary to estimate one of them, and the other will consequently be known in the manner indicated in a later paragraph.

Our second rule is that a knowledge of either the correct exposure *or* the correct time of development is a complete guide to both exposure *and* development, because exposure and development are dependent variables of which one is inversely proportional to the other.

Before proceeding to the third and last rule, let us consider this "give and take" in the exposure and development of bromide paper. It is totally different to the exposure and development relationships in the case of photographic plates and lantern slides. With the latter, increase in the time of development leads to a steady increase in contrast until a degree of contrast is reached far beyond the requirements of practical photography. There is no "give and take" in exposure and development when making negatives and lantern slides, and we acknowledge this in practice by calculating exposures and calculating times of development quite independently of one another, making no alteration in the development time, because of variations in exposure. Bromide paper, however, rapidly develops to its maximum contrast coincident with the possible attainment of maximum black, and further development does nothing but make the print darker. It is in this stage that further development can compensate for lack of exposure. It is this "give and take" peculiar to bromide paper and similar materials such as gaslight paper which leads to the announcements in paper makers' advertisements to the effect that their particular paper possesses exceptional "latitude." The use of the word "latitude" in this connection is most unfortunate. The same word is already used in connection with plates to describe the relationship between the range of light-intensities in the subject and the range of light-intensities which the plate is capable of rendering with truth. During printing the negative is the subject, so far as the printing paper is concerned, and the negative range and the paper exposure range must approximately coincide if a good print is to be obtained. There is no "latitude," because there has to be "coincidence." The terminology of photography is already sufficiently confused, and the use of one word to describe two totally different phenomena is to be deprecated. I would suggest that this "give and take" in the exposure and development of bromide paper be described as "pliancy." It is an ugly word, but fairly descriptive. A paper which will stand a considerable decrease in exposure, and will then allow prolonged development to produce a normal print without fog or stain, is a very "pliant" paper. The particular batch of Kodak Velvet Bromide paper which provided the figures for Tables I and II possessed a minimum development time of 60 seconds for the attainment of maximum black under certain developer and temperature conditions. There was no difficulty in getting fog-free and stain-free prints under the same developer and temperature conditions with 3½ times that time of development, and, of course, a corresponding *decrease* in exposure. The pliancy of that paper was I—3½, and it was a very good specimen of its kind. There are many papers whose pliancy is less than I—2, so that prolongation of development to compensate for lack of exposure is prevented by fog and stain.

The third rule is a very simple one. The practical stop to further development is the onset of fog or stain, or both. We can define the maximum development allowable as that which just stops short of these two undesirable defects.

These three simple rules descriptive of the exposure and development properties of bromide paper are all we require to formulate a scheme for the production of bromide prints accurately by rule without any possibility of failure so far as exposure and development are concerned. Briefly summarised, they are as follows:—

(1) The minimum time of development is that which is just sufficient to allow of the attainment of maximum black.

(2) Between the minimum and maximum times of development the exposure given and the development required are inversely proportional to one another.

(3) The maximum time of development is that which just falls short of fog or stain, or both.

These rules have been stated primarily to describe certain exposure and development properties of bromide paper in order to devise a scheme of work. They should also be considered in conjunction with the first part of this paper. It is obvious that development by inspection takes little, if any, notice of them, nor does it allow the photographer to judge whether they are being complied with or not. The fact that exposure and development relationships exist and are ignored is a measure of the failure of development by inspection.

The Choice of the Factorial Scheme in Preference to Others.

It has been shown that exposure and development need not both be calculated because of the definite relationship that exists between them. A correct exposure may be defined as that which allows of development above the minimum time but below the maximum allowable time, and produces in that time a print of the required depth. We are faced, therefore, with two alternative schemes:—

I. The calculation of correct exposure (in some manner) so that the attainment of the desired depth of print during development is indicative of the correct time of development; or,

II. The calculation of the correct time of development (in some manner) so that the attainment of the desired depth of print in that time is indicative of correct exposure.

Let us examine the practical possibilities of scheme I. In order to calculate the correct exposure we require to have the following information:—

(*a*) The strength of the printing light incident upon the surface of the negative during printing.

(*b*) The measure of the maximum density of the negative through which the minimum light action on the paper beneath it is required.

(*c*) The influence of the colour of the negative upon the time of exposure in conjunction with the spectral composition of the printing light.

(*d*) The speed of the paper.

(*e*) The depth of print required.

It is perfectly obvious, without any elaboration of those conditions, that the precise calculation of correct exposure

would tax the capacity of a well equipped laboratory, and is quite beyond the capacity of the ordinary photographer. It is not possible to calculate exposure with precision *preparatory* to exposing the print, and we use it as a factor in the determination of correct development.

Now let us explore the possibilities of scheme II. If we can determine a correct time of development the problem is solved. We have only to make an exposure trial strip and develop it for that correct time of development, and the portion of the trial strip which is correctly exposed is that which exhibits precisely the depth of print we want. That exposure given to the final print, which in turn is developed for the same correct calculated time, yields the print desired with absolute certainty. Can we devise a method of calculating or indicating the correct time of development for any brand of bromide paper under all the variable conditions of temperature and developer irregularities which occur in practical work? I have in the past shown that the Watkins' method of factorial development, however uncertain its indications may be in the development of plates, is an exceedingly accurate index as to the degree of development of bromide paper. A very great deal of experimental work has convinced me that bromide paper can be developed to a fairly precise pre-determined degree by noting the time of first appearance of the image and multiplying it by a factor, the resultant time being "a correct development time." Each developer has its own factor. That for amidol (Kodak formula) is 12. Our choice of a system for producing bromide prints by rule must fall upon Scheme II as being the simpler and, indeed, the only possible method, and it is rendered possible by the application of the Watkins' method of factorial development. The choice of a factor for any developer is limited by Rules I and III given above as to the minimum and maximum development allowable. With amidol (Kodak formula) the minimum factor is 10. With a very "pliant" paper the maximum factor is about 30, for further development is very liable to give fog or stain. Whatever factor be chosen, and for many reasons 12 is a good choice, both the trial strip and the final print must of necessity be developed to the same factor (Watkins) if the former is to be a guide to the exposure of the latter. Except for the purpose of altering the shade of sepia in subsequent sulphide toning, there is no need to depart from this factor of 12. It ensures the attainment of maximum black if the negative transmits a printing exposure which suffices, and it is far short of the onset of fog and stain if the photographer is careful in the choice of a bromide paper made by a firm of good standing. There are but few bromide papers on the market made by firms of repute with which it has not been tried, and it yields perfect results with all that have been so tried.

Summary.

The making of bromide prints by inspection fails in many instances because inspection does not tell the worker with certainty that *both* exposure *and* development are right. The common fault is over-exposure, followed by under-development, in an attempt to prevent the print from becoming too dark. A trial strip is no remedy for this, because the same faulty procedure is adopted with the trial print. The statement that development appears to stop when it has been carried far enough is untrue.

The making of bromide prints by rule is made possible by the Watkins' factorial method of development. With the guidance of this development rule correct development is ensured. If development be right, then the attainment of the required depth of print in that development time is proof of a correct exposure. The correctness or otherwise of both exposure and development is therefore known with certainty.

There are many who doubt the need for rule, and there will remain many who continue to doubt it. It is interesting to note, however, that there has never been published in any photographic text-book or pamphlet, so far as I know (and I have read most of them) any definition whatever of what constitutes correct exposure and correct development of a bromide print in a manner which enables the reader to apply that definition to his own work and obtain success with certainty. Correct exposure and correct development cannot be defined in terms of "development by inspection."

But the rules that have been given in this paper, and the scheme of print production based thereon, enables a complete and accurate description of correct exposure and correct development to be given. We can define them so that it does not matter what is the strength of the printing light, or what is the density or colour of the negative, or what the developer may be or what are the development peculiarities of the paper. It is a definition which is a practical working one, for it can be applied in practical work in any dark-room in any part of the world, whether it be hot or whether it be cold. It is as follows:—

The correct exposure for a bromide print is that which, when developed with amidol (Kodak formula) to a Watkins' factor of 12, yields a print of the desired depth.

That definition is based upon experimental evidence. Further experimental evidence of an opposite nature alone can upset it. It is useless for opponents merely to deny it. We cannot hope to help those who are inexpert unless we are able to define exactly the conditions to be fulfilled in order to yield the desired result. If the definition given above is untrue, then we must find another one if bromide printing is not to remain a matter of pure chance when in the hands of those who are struggling to learn. If there is another definition in existence which is equally precise and equally capable of being realised in practice I would be glad to hear it, for it does not yet seem to have appeared in print.

There is an interesting point of commercial importance illustrated in Table II. The two prints F and H are equal in all practical respects. Print F took 30 seconds to print and 60 seconds to develop, a total of 90 seconds in all. Print H took 10 seconds to print and 180 seconds to develop, a total of 190 seconds in all. From the point of view of time involved in production, print F is the better commercial proposition. There have been some short-sighted and ill-considered criticisms of the factorial development of bromide paper as to its utility to the trade photographer. It appears to have been overlooked that the development of one print factorially at the beginning of a term of work yields a *total* time of development applicable to the particular batch of bromide paper in use when certain developer and temperature precautions are taken. Trade photographers will probably admit that their aim is the highest quality combined with the shortest possible expenditure of time. It is reasonably certain that a high degree of quality and a vast saving of time and material could be made by substituting rule for experience. I have seen skilled and experienced bromide printers temporarily baffled by some unknown condition which was leading to loss of quality, wasting time and material trying to overcome the difficulty. Not the least advantage of bromide printing by rule is the readiness with which changed working conditions can be recognised instantly, so that faulty work, the result of an unrecognised change, may be avoided.

The correct exposure for a bromide print is that which, when developed with any developer to an appropriate Watkins' factor, yields a print of the desired depth.

At the present time this is the only definition in existence which has any value in practical work.

B. T. J. Glover.

Welsh National Exhibition.—A booklet descriptive of the exhibition to be held during next summer at Cardiff has been issued from the headquarters of the Welsh National Exhibition, 4, Mount Stuart Square, Cardiff. In the section devoted to industrial arts, photography and colour photography are to be included, and the making and operation of moving pictures will be exhibited.

THE THEORY AND TECHNIQUE OF LIGHT-FILTERS.

[The following is an important paper on the principles of the action of light-filters and on the practice of their preparation and use. It is the work of a Russian physicist, M. G. V. Potapenko, and was first published in the Journal of the Russian Physical and Chemical Society (Chemical Section) 1916, vol. 48, p. 790. We owe the accessibility of the paper to Dr. C. E. K. Mees, by whom the translation from Russian has been made. Dr. Mees while rendering the text into English, does not thereby wish to imply his agreement with everything contained in it. He has refrained from exercising a translator's right of commentary except in one or two instances which particularly call for correction. The fact that he has made the translation and given us the opportunity of publishing it, may be taken as an indication that he regards the paper as a contribution to the literature of light-filters of exceptional value.—EDS. "B.J."]

(*Continued from page* 510.)

An even greater number of investigations have resulted in the successful preparation of sets of three filters for tri-colour photography, which are usually termed standard filters if they are employed for photography by the so-called additive process, and which divide the spectrum into three parts—red, green, and blue-violet. The most extensive work on this question was done by Eder[25], who definitely stated the limits of transmission for standard filters and gave formulæ for their preparation. After König had made available a whole series of organic dyes suitable for the preparation of light-filters, which were placed on the market by the firm of Meister, Lucius & Brüning, many workers tried to prepare standard filters of the greatest precision, and at the present time the formulæ given by Von Hübl[26] have been generally adopted as representing filters of the highest accuracy and transparency. The limit of the red filter prepared by him lies near 585$\mu\mu$ which corresponds to the middle of the yellow part of the spectrum. The green filter transmits light between 585$\mu\mu$ and 495$\mu\mu$, so that its curve terminates in the middle of the blue-green part of the spectrum. Finally, the third filter transmits the blue and violet rays from 495$\mu\mu$ to 400$\mu\mu$.

At this point the limit of a filter must be defined more exactly. The absorption curve of a dye is never perpendicular to the axis, but is inclined to it at a greater or smaller angle. If we refer to Fig. 1 we shall see that the absorption curve of this filter terminates near 620$\mu\mu$ and 458$\mu\mu$ but these values cannot be taken as the limits of the filter since the absorption curve could easily be extended further if it were possible to increase the precision of measurement, and thus determine the transmission in other parts of the spectrum, such as near 640$\mu\mu$ or 450$\mu\mu$, where it is very small, and therefore cannot be measured. From equation 8 we see that when e=1.0 the absorption of the light amounts to 90 per cent., when e=2.0 it is 99 per cent., and when e=3.0 it is 99.9 per cent., *i.e.*, scarcely any light is transmitted by the filter. The practical limit of transmission for a filter may be considered to be the wave-length which corresponds to a value for e of 2.0, when the filter transmits 1 per cent. of the light; for all points on the absorption curve beyond this the light transmitted will be less than 1 per cent., and can be neglected in practice. In conformity with this criterion Hübl used the following concentrations of dyes in order to obtain filters whose limits are those given above.[27]

Rose Bengal	1.5 H.	for the red filter.
Tartrazine	2.0 H.	
Patent blue	0.7 H.	for the green filter.
Tartrazine	2.5 H.	
Acid Rhodamine	3.0 H.	for the blue filter.
Patent blue	1.0 H.	

Von Hübl's green and blue-violet filters, however, are sometimes unsuitable since they transmit much red light of long wave-length near 700$\mu\mu$, which is quite visible. They can therefore be considered monochromatic filters only for photographic use, since the most orthochromatic emulsions have very little sensitiveness to these long waves. In order to obtain more strictly monochromatic filters other combinations of dyes must be used, but up to the present it has not proved possible to absorb entirely the extreme red light, though its intensity can be greatly weakened. In the preparation of liquid filters similar difficulties are not met with, since numerous coloured inorganic compounds can be used, solutions of which completely absorb the red light, but these, of course, are unavailable for use in film form. As early as 1903 König[28] showed that naphthol green was very suitable for the absorption of the red light transmitted by the standard green filter, but it cannot be used for the blue-violet filter since it has a second maximum of absorption near 450$\mu\mu$, and it therefore diminishes the transparency of the filter to a great extent. The author has experimented with toluidine blue, and after a number of trials has obtained a series of standard filters which completely absorb light of 700$\mu\mu$, transmitting only waves longer than 710$\mu\mu$, which are scarcely visible. These waves also can be absorbed, but at the cost of too great a loss in the transparency of the filter; in addition to which the amount of red light transmitted is so small that it can only be detected spectrographically with long exposures.

In these experiments a peculiarity of vision was very noticeable. Under normal circumstances the retina is sensitive only to rays of shorter wave-length than 765$\mu\mu$, when these rays are absorbed by a filter the eye begins to see rays from 770 to 775 $\mu\mu$, and when these are absorbed light is observed up to 790$\mu\mu$, and so on. How far such observations could be pushed is not definitely known, but Stefanik,[29] using a filter transmitting only the infra red end of the spectrum, could see light whose wave-length was 1,000$\mu\mu$.

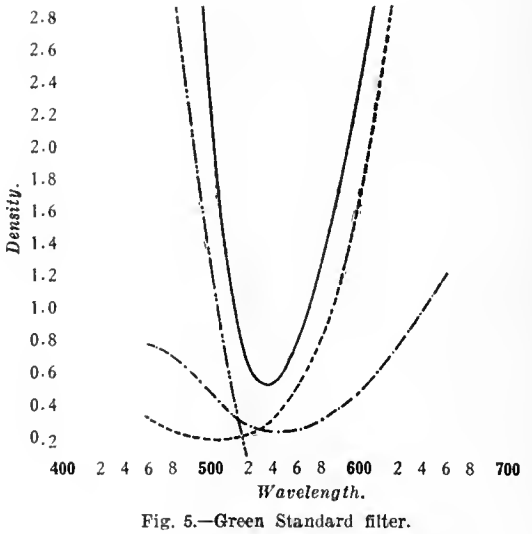

Fig. 5.—Green Standard filter.

The third light-filter of the series was made from the following dyes :—

Fig. 5.—
- Absorption curve of patent blue in concentration 0.45 H. .....
- Absorption curve of naphthol green in concentration 0.4 H. – – – – –
- Absorption curve of tartrazine in concentration 1.5 H. – – – – –
- Absorption curve of light-filter ——

The technical details for the preparation of filters will be given later. We will here deal only with the formulæ which were used for this series of standard filters. The first of them, the red filter, was made according to Von Hübl's formula given above.

Rose Bengal	1.5 H.
Tartrazine	2.0 H.

27. Hübl, *Die Phot. Lichtfilter*, p. 101.
28. König, l.c.
29. Stefanik, C.R., CXLII., 1906, pp. 986 and 1569.

For the green and blue-violet filters the following combinations of dyes were used :—

Green standard filter, 585$\mu\mu$ to 495$\mu\mu$.

Patent blue	0.45 H.
Naphthol green	0.4 H.
Tartrazine	1.5 H.

The absorption curve of this filter is given in Fig. 5, in which are shown also the curves corresponding to the several dyes. All

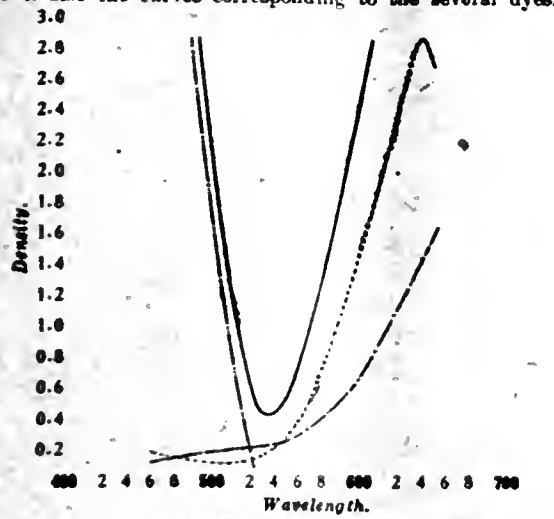

Fig. 6.—Filter of Patent Blue, Toluidine Blue, and Tartrazine.

Fig. 6 {
- Absorption curve of patent blue in concentration 0.35 H ——————
- Absorption curve of tolnidine blue in concentration 0.75 H. – – – – – –
- Absorption curve of tartrazine in concentration 0.25 H. – – – – – –
- Absorption curve of light-filter ——————

Blue-violet filter (595$\mu\mu$—400$\mu\mu$).

Tolnidine	1.8 H.
Acid rhodamine	1.4 H.

the absorption measurements made in the course of this work were carried out on a König-Martens-Grunbaum spectrophotometer in which the light-filter under investigation was placed on one side, and on the other an exactly similar but undyed gelatine film, thus compensating for the absorption of the gelatine and the reflection from the surface.[30]

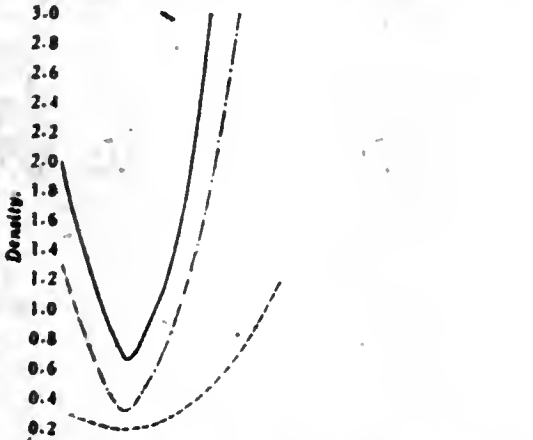

Fig. 7.—Blue-violet filter of Tolnidine and Acid Rhodamine.

Fig. 7. {
- Absorption curve of toluidine blue in concentration 1.8 H. ——————
- Absorption curve of acid rhodamine in concentration 1.4 H. – – – – – –
- Absorption curve of light-filter ——————

30. For the apparatus and method of measurement see I. Plotnikoff. *Photochemische Versuchstechnik*, Leipzig, 1912, p. 133.

The slit of the spectro-photometer was illuminated by means of a gas burner or a Nernst lamp.

In the formulæ given above toluidine blue can be substituted for the naphthol green The formula will then be :—

Patent blue	0.35 H.
Toluidine blue	0.75 H.
Tartrazine	2.5 H.

The absorption curve of this filter is given in Fig. 6.

Fig. 7 gives the absorption curve of this filter.

Instead of acid rhodamine, rhodamine B is often applied, the curve of which is of a somewhat different form, more red light being transmitted by rhodamine B than by acid rhodamine.

The filter made from this dye is not sufficiently transparent, since it is necessary to increase considerably the concentration of the tolnidine blue.

In Fig. 8 are given the curves of Von Hübl's filters. By comparison with these it is clear that the elimination of the red rays from the filters has made it necessary to sacrifice transparency.

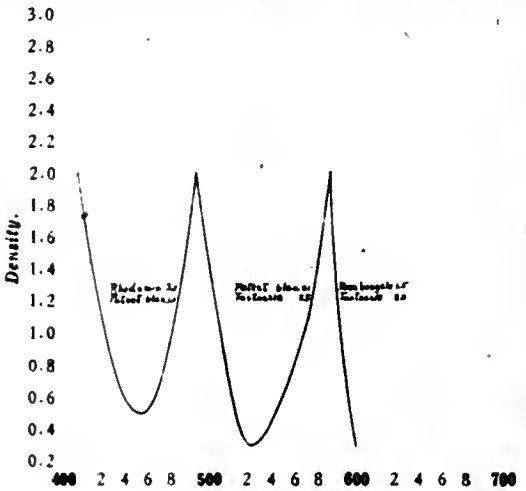

Fig. 8.—Von Hübl's filters.

However, our series of standard filters makes it possible to work with emulsions of greater red-sensitiveness and thus increase the accuracy of the work. The results obtained are summarised in the following table :—

STANDARD (ADDITIVE) FILTERS.

No.	Light transmitted.	Dyes.	Concentration.	Limits.	Remarks
1.	Red	Rose bengal	1.5 H	–585$\mu\mu$	Hübl's filter
		Tartrazine	2.0 H		fig. 8
2(a).	Green	Patent Blue	0.45 H		
		Naphthol Green	0.4 H	585–495$\mu\mu$	fig. 5
		Tartrazine	1.5 H		
2(b).	Green	Patent Blue	0.35 H		
		Toluidine Blue	0.75 H	585–495$\mu\mu$	fig. 6
		Tartrazine	2.5 H		
3.	Blue & Violet	Toluidine Blue	1.8 H	495–400$\mu\mu$	fig. 7
		Acid Rhodamine	1.4 H		

All the above-mentioned dyes are acid; they mix well in one solution and do not precipitate each other.

Parallel to the standard additive filters we may have a series of subtractive filters, used in three-colour photography by the subtractive process from which they derive their name.[31].

The shape of their absorption curves has already been discussed, and one of these subtractive filters has been given in Fig. 3. We will not discuss them further since they do not exhibit any points of especial interest: for formulæ the reader is referred to the papers of König, Von Hübl, and Eder.[32]

Let us turn now to the theory of compensating filters. If we examine the absorption of the yellow compensating filter, given

31. For a discussion of the additive and subtractive processes of three-colour photography, the reader is referred to the books and articles by König, Hübl, and Eder already referred to.

32. König, l.c. Hübl, *Die Dreifarbenphatographie*. Eder, *Spektral-Stud. über Dreifarbenphot*, Denkschrift der mat. natur-Wiss.

in Fig. 2, we shall see that it is characterised by an unidirectional curve, which stretches continuously from the red end of the spectrum to the violet. Compensating filters are mostly used for the correction of the inaccurate reproduction of colours by photographic emulsions, the maximum of sensitiveness of which does not accord with the maximum sensitiveness of the eye. According to Schwarzschild[33], ordinary gelatino-bromide emulsions are most sensitive to light of λ 430 while the maximum sensitiveness of the eye is in the green.[34]

By special sensitizing the curves of sensitiveness of photographic plates can be extended towards the red, but they never coincide with the curve of the eye.

Compensating filters are used to correct this difference, absorbing the violet and blue light, and therefore appearing of a yellow colour. Sometimes such compensating filters also absorb the red and thus appear of a greenish colour. All artificial light-sources are very rich in red rays in comparison with diffused sunlight, and such greenish filters are therefore used with them. Ellis[35] has measured the intensity of various light-sources for the three spectral regions, and gives the following results :—

	Ratio of Intensity.		
	Red.	Green.	Blue.
Diffused daylight	100 :	100 :	100
Nernst lamp	100 :	515 :	11.3
Carbon filament lamp	100 :	45 :	7.5

From this it can be seen that the compensating filter for a Nernst lamp, for example, will have an absorption curve whose ordinate values corresponding to the above-mentioned spectral regions will have the ratio :—

$$100 : 51.5 : 11.3.$$

Such a filter will be of a bluish-green colour, and the light transmitted by it will resemble daylight, corresponding to its selective absorption.

The theory of compensating filters was first worked out by Callier,[36] who published the method of finding the absorption curve of a filter adapted to any emulsion.

It is well known that the blackening S of a photographic plate is proportional to the quantity (It) where I is the intensity of the illumination and t is the time of exposure, *i.e.*,

$$S = k\ It \qquad (9)$$

where k has a value ranging from 1 to 2, increasing with the time of development.[37] The blackening of the plate is determined photometrically from the relation

$$I = I_0 10^{-S}$$

analogous to formula (5) where I_0 is the intensity of the light falling upon the plate, and I is the intensity of the light transmitted.

If we photograph a spectrum and express the measured densities S as a function of the wave-length we obtain a curve characteristic of the plate used, and corresponding to the equation

$$S = \phi\ (\lambda).$$

If the ordinate values of this curve are diminished by an amount c it is obvious that we obtain the same result as if the light by which the curve were made had been screened by a filter having absorption coefficients equal to c. In Fig. 9 is given the spectral curve of a gelatino-bromide plate sensitized with pinachrome and also the visual intensity curve of diffused daylight, measured by Vierordt[38] and corrected by Callier from Köttgen's[39] observations.

In order to render these two curves as much alike as possible it is necessary to use the light-filter whose absorption curve is shown as the dotted curve on the diagram. The ordinates of this curve are obtained simply by subtracting the ordinates of the curve A N from those of the curve A M.

Usually orthochromatic plates do not have such simple spectral curves as that shown in Fig 9 : they generally have two maxima of sensitiveness, with a minimum between them, this usually being the green part of the spectrum.

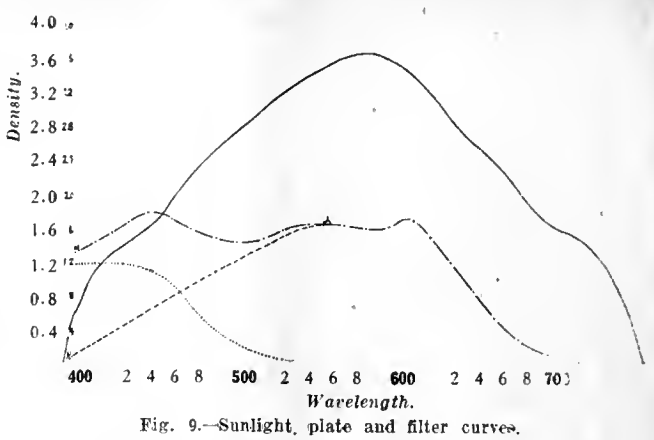

Fig. 9.—Sunlight, plate and filter curves.

Fig. 9. { Intensity curve of diffused sunlight ——— ; Curve of pinachrome sensitized plates according to Callier – – – – – ; Desired form of characteristic curve ····· ; Absorption curve of compensating filter ····· }

The compensating filters for such plates should also have absorption curves of a wavy form and lose their simple character.

An example of such a filter is given in Fig. 10, and its absorption curve can hardly be classified under any one of our three classes.

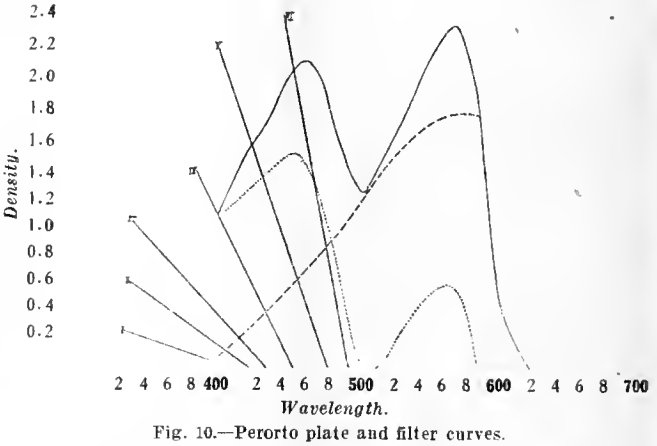

Fig. 10.—Perorto plate and filter curves.

Fig. 10. { Characteristic curve of Perorto plate (green label), according to Callier ——— ; Required curve ····· ; Absorption curve of compensating filter ····· }

It appears to be a combination of the curves corresponding to the compensating and the subtractive filters. On the existence of such minima of sensitiveness for orthochromatic plates in the green part of the spectrum is based the use of green safelights for their development.[40]

A formula for such a filter was given by Von Hübl.[41] The yellow filters commonly found in commerce have a steeper absorption curve than those shown in Figs. 2 and 3, and absorb the blue, violet, and ultra-violet rays.

THE LATE MR. S. H. FRY.—The estate left by the late Mr. S. H. Fry, formerly secretary of the Professional Photographers' Association, has been valued for probate at £12,219 (gross).

PHOTOGRAPHERS' ASSOCIATION OF THE PACIFIC NORTH-WEST.

Seventeenth Annual Convention.

The seventeenth annual convention of the Photographers' Association of the Pacific North-West was held in Vancouver from August 2 to August 9, under the presidency of Mr. Thomas Gagnon, of Tacoma. The Association has a membership of about 400, 200 of whom attended the Convention, which on all hands was pronounced to be the most successful gathering of photographers on the Pacific Coast which has hitherto been held. The Convention had its headquarters at the Dominion Hall, Vancouver, where members were officially welcomed by the acting Mayor and by the American Consul-General. On the opening day, Mr. J. C. Abel, general secretary of the Photographers' Association of America, gave an address on cost systems and cost finding. As a representative of that Association, he emphasised its importance to all photographers in America as regards national advertising and other co-operative movements. He outlined a plan formulated at the last meeting of the P.A. of A., whereby it is proposed to undertake a campaign of national advertising in the interests of the professional photographer. Various means of financing the undertaking were mentioned.

In a talk on "A New Idea for the Craft," Mr. Dick O'Connor, of Vancouver, urged that there should be combined with the present form of convention a photographic "clinic," similar to what was so successfully adopted at a convention of dentists. He advocated that they should secure the services of the most expert photographers for demonstrations and short courses of instruction in the various branches of photography in which they were interested. This suggestion was viewed very favourably by the Convention, and it is hoped that at next year's meeting the opportunity will be provided for individual instruction in any part of his work in which a member feels weak.

Other addresses were given on "Character Analysis," by Mr. A. L. Struthers, and on "The Value of Organisation," by Mr. J. T Crowder, president of the Retail Merchants' Association.

A great feature of the Convention was the exhibition of photographic work by British, American, European, and Japanese professionals. Several hundred pictures were brought together, including a fine collection of the work of English and Scottish photographers sent by Mr. Marcus Adams. Individual exhibits were sent by Mr. W. Crooke and Mr E. Drummond Young. The Canadian Trade Commissioner in Japan had obtained for the Association a large collection of the work of leading Japanese photographers, and the exhibition, of course, included the representation of Canadian studios on the Pacific Coast and in the Prairie Provinces. This exhibition was thrown open to the public, and was largely visited by residents in Vancouver.

We are informed that a grand sweepstake prize went to Mr. W. Crooke, of Edinburgh, and that the first and second awards to foreign exhibits were made to Mr Lumney and Mr. Herbert Lambert. The Curtis studio, of Seattle, was awarded first place for a study of mounted Indians, entitled "The Vanishing Race," and other Salon honours went to Mr. H. C. Knight, of Victoria, B.C., and Messrs. Dupras and Colas.

So appreciative were members of the Convention of the enormous labours which the officers of the Association had undertaken in making the meeting a success that they decided it would be unfair to re-elect them for the further session. The following officers were therefore elected:—President, W. G. McCormick, of Friday Harbor; vice-president, Mr T M Grady, of Seattle; secretary-treasurer, Wilfred Gibson, Victoria, B.C. It was also decided to increase the subscription to the Association to 6 dollars per annum.

Bird Photography.—The camera (writes "Nature") is being used increasingly to elucidate the habits of birds, and striking success has been achieved by Dr. Overton in his observations on the great horned owl, described in "Natural History" (vol. xxi., No. 2). It has hitherto been supposed that the bird attacks its enemies and prey by means of its wings or bill. The remarkable series of photographs which are used to illustrate Dr. Overton's article clearly demonstrates, however, that the bird attacks solely with its feet. We have seldom seen so conclusive a collection of photographs of birds.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 15 to 20 :—

Plates.—No. 22,043. Manufacture of photographic plates and films. H. E. Coley.

Colour Cinematography.—No. 21,671. Colour cinematography. F. W. Donisthorpe.

Cameras.—No. 21,873. Automatic photographic cameras. F. C. V. Laws and C. M. Williamson.

Toy Camera.—No. 21,830. Toy camera. G. C. Nesbitt.

Lens Device.—No. 21,718. Devices for indicating reduced light intensity of apertures of lenses when used at considerable extension of camera. W. G. Rickman.

Cinematography.—No. 21,747. Optical devices for viewing photographic, etc., film pictures. H. F. G. Smith and A. L. Stouvenaut.

Cinematography.—No 21,748. Attachment for photographic, etc. films or film pictures and means for filing such pictures. H. F. G. Smith and A. L. Stouvenaut.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Two-colour Cinematography.—No. 165,826 (June 4, 1919). The invention relates to a two-colour process of colour cinematography in which a yellow screen, which may be of flavazine, is employed.—W. Friese Greene (the late), 41, Portsdown Road, Maida Vale, London, W.9, and Colour Photography, Ltd., 3, St. James's Street, London, S.W.1. (Details are given on another page in the "Colour Photography Supplement.")

The following complete specifications are open to public inspection before acceptance :—

Cinematographs. No. 167,737. Cinematographic apparatus. O. Messter.

Stereoscopy. No. 167,751. Classifying apparatus for examining stereoscopic or panoramic views. E. J. Delens.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Trefoil Design ("As de Trefle").—No. 416,088. Photographic paper. Grieshaber Frères and Cie, also trading as Société des Produits Photographiques "As de Tréfle," 27, Rue du Quatre-Septembre, Paris, France, manufacturers. June 13, 1921.

FORTHCOMING EXHIBITIONS.

September 10 to October 8.—London Salon of Photography. Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, SEPTEMBER 6.

Hackney Phot. Soc. Print and Slide Competition

WEDNESDAY, SEPTEMBER 7.

Bradford Phot. Soc. Evening Excursion to Chellow Dene.

THURSDAY, SEPTEMBER 8.

North Middlesex Phot. Soc. "The Chemical Side of Photography." J. H. Harris.

SATURDAY, SEPTEMBER 10.

City of London and Cripplegate P.S. Outing to Wimbledon Common.

Glasgow and W. of Scot. Amateur Phot. Assoc. Excursion to Erskine Grounds.

Hackney P.S. Outing to Waltham Cross. F. C. Toye.

Hammersmith (Hampshire House) P.S. Outing to Ickenham

North Middlesex P.S. Outing to South Mimms.

CROYDON CAMERA CLUB.

"Odds and Ends by Oddities," so ran the announcement for last week's fixture, which, in the opinion of the chairman, Mr. F. C. Reynolds, might be excused by the licence allowed bill sticker Sellors.

The Brothers, L. J. Hibbert and J. W. Purkis (a strong combination of talent) provided the main turn with a divertissement on P.O.P., supported by a powerful company of test-tubes and chemicals. The "brothers" are to be congratulated on dealing very interestingly with a hackneyed subject in a quite unhackneyed manner. Mr. Hibbert explained and demonstrated practical procedures, and was followed step by step by Mr. Purkis with instructive test-tube experiments, and not once did the demonstrators jam. In this way, among other things, was illustrated the necessity of washing out the free silver nitrate before toning, and the production of stains by the introduction of minute traces of hypo into the washing water prior to, and after, toning.

A P.O.P. emulsion of Abney's formula was prepared and utilised in a novel and pretty experiment. The warm emulsion was poured into a rectangular glass tank, and allowed to set. A clear-glass type of negative, representing a horse with two amateur jockeys up, was then placed in contact with the tank and illuminated by an electric arc. The treasurer having offered level money on the horse for a place, the bet was promptly taken by the "office boy." This led to a disagreement between the two owing to the heat of the arc eventually melting the emulsion and causing the picture of the horse, in sadly contorted state, to mount to the top of the tank, which the last-named stoutly maintained was not "a place within the meaning of the Act." A second trial with the arc removed to a greater distance was completely successful in securing an adequate representation of the negative. A concluding experiment consisted in toning a shilling into a sovereign to recoup the lecturers for their outlay.

An interlude was next afforded by a member exclaiming that he had been suddenly struck with softening of the brain. He based this opinion on being unable to comprehend, despite strenuous concentration, the second paragraph of an article by the "Bandit" (in the "A.P." of August 24), which he read aloud. The case of the afflicted was not considered hopeless.

The evening terminated with Mr. J. Walker discoursing on the unorthodox entry of light into film-packs, which he resented. In one adapter he had kept the intruder out by glueing strips of velvet one over the other along the top of the back so that they exercised just sufficient pressure.

DEATH OF MR. COOPER HEWITT.—Mr. Peter Cooper Hewitt, the well-known American scientist and inventor, died on August 25 at the American Hospital, Neuilly. He was in his 61st year, having been born at New York on March 5, 1861. Mr. Cooper Hewitt was educated at the Stevens Institute of Technology, Hoboken, and at Columbia University. Throughout his life he devoted himself to the study of economics, physics, electricity, and chemistry. He was probably most widely known as the inventor of the "Cooper-Hewitt lamp," which inaugurated a new principle in electric lighting, and has been largely adopted in photographic studios.

Commercial & Legal Intelligence.

NEW COMPANIES.

STEREOSCOPIC MOTION PICTURE SYNDICATE, LIMITED.—Registered August 20. Capital £100 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in stereoscopic cinematograph cameras and projectors, film producers and manufacturers, etc., and to adopt an agreement with E. H. Wright. The first directors are: E. H. Wright, 49, Cresswell Road, Twickenham; E. F. Savage, 36, Brookfield, Highgate, N. Qualification: 1 share. Registered office: 152, Finsbury Pavement, E.C. Private Company.

News and Notes.

THE CLUB PHOTOGRAPHER.—Members of the Portsmouth Camera Club provide the contributions to the current issue of the "Club Photographer." Dr. Bertram Stone has some notes on methods in Nature photography; Commander E. J. Mowlam writes on seascape photography; and Mr. R. Parker gives formulæ for range of tones in sulphide toning.

CELLULOID SOLUTION.—A correspondent of the "Pharmaceutical Journal," writing on the making of varnish from celluloid, says:—The best celluloid is old Kodak film, cleaned *both* sides. It makes no difference whether exposed or not. I use:—

Clean film		1 oz.
Acetone Amyl acetate	equal parts	10 ozs.

First polish the article with anything liquid or paste. Then thoroughly clean with plenty of methylated spirit and soft rag. Set aside to dry—say half an hour—then polish up again with a clean polishing cloth or chamois, apply the lacquer with a soft large brush; use plenty, and leave to dry. Another correspondent, Mr. R. J. Stratton, writes:—My experience is that ordinary clear celluloid (such as old photographic films, cleaned from emulsion) is sufficiently soluble in acetone to form a thick syrupy solution, but that the solution dries semi-opaque with a patchy whitish appearance. If, however, equal parts of amyl acetate and acetone are used, the film formed on drying is perfectly transparent. A smaller proportion of amyl acetate might suffice; this could easily be decided by experiment.

PHOTOGRAPHY ON THE LOST AIRSHIP.—Photographs were being taken on the ill-fated airship (R38) when it fell into the Humber on the 24th ult. Mr. Arnold Bateman, one of the Government scientists on board at the time of the accident, has given to the Press an account of the incidents leading up to the disaster, and of his own wonderful escape. Mr. Bateman was on board as one of the representatives of the National Physical Laboratory, Teddington, taking measurements of the forces that act on the control surfaces, with a view to testing airworthiness. He was in the tail of the airship taking photographs of the pressure on the fins, and says:—"There were three of us making these measurements, which are for the guidance of designers of future airships in relation to the fins, which have always been a doubtful point. . . . I took up my position, and had been taking photographs for about 15 or 20 minutes when the accident occurred. It was swift and complete. . . . My parachute was handy, and I attached myself to it and jumped overboard." Mr. Bateman, who was one of the five saved out of a crew of forty-nine, was picked up in a dazed condition by the barge "Klondyke," of Ramsgate.

MEASURING THE GLOSS ON PAPER.—L. R. Ingersoll has designed an instrument for measuring the gloss on paper. When light falls on a piece of paper, part of it is diffusely reflected and part is reflected specularly—that is, as from a mirror. This latter part is found by experiment to be almost completely plane-polarised, when its angle of incidence on the paper is about 57.5 degrees. An eye-piece is set so as to receive the specularly reflected beam which has mingled with its also diffused light. Gloss is defined as the fraction of the brightness of the composite ray, due to the plane-

polarised light contained in it. This constituent of the beam is eliminated by passing the light through a nicol, and from the setting of the latter it is possible to calculate the desired fraction. There still remains an arbitrary element, the angle subtended by the source of light, and, since this is so, the author takes the angle through which the nicol must be turned from a certain setting as a convenient, though not an absolute, measure of the gloss. On this scale blotting-paper reads 20 degrees; Solio, 50; ordinary magazine paper, 25 to 40. An absolute determination of the gloss as above defined can be got by using two different angles of incidence. The instrument, the glarimeter, is portable and strong. Only 15 or 20 seconds are needed for a determination, and darkening the room is not necessary. Its use is not limited to paper. The gloss of paints, varnishes, textile fabrics, and finishes can be investigated with it. Its special employment seems to be for controlling the calendering process of papers. The instrument in its general outlines was devised some years ago, but the famine of optical parts during the war delayed its completion. Keiser, in Germany, appears to have developed a similar instrument independently, though later (see "B.J.," February 11, 1921, p. 78).

Correspondence.

SULPHIDE TONING.

To the Editors.

Gentlemen,—The writer desires to call attention to two small matters in connection with the communication, "Experiments on Sulphide Toning," which appeared in the July 29 number of this journal. In each case the statements made, while not incorrect in themselves, are misleading as they stand, and should have been amplified in the original paper.

First, the use of a bleach bath of potassium ferricyanide with potassium chloride suggests the intention of converting the silver of the image to silver chloride (see page 447, expt. B1). There was no such thought, however, in these experiments; and, in fact, the ferricyanide-chloride bleach of the composition used yields an image which consists mainly of silver ferrocyanide, and in which it is difficult or impossible to detect any silver chloride. And, as being of some importance in practice, it should have been specifically pointed out that while true conversion to a chloride, as by means of a permanganate-chloride bleach (see page 448, expt. B11), gives on subsequent sulphiding a tone which is somewhat more purplish than normal, a decided deviation in the *opposite* direction results from the use of the ferricyanide-chloride bleach. This latter bath, it should further have been specifically mentioned, appears identical in action (both speed and tone) with ferricyanide alone.

Second, in footnote 1, on page 448, the wording, through lack of amplification, is such that the impression is given that the writer's experiments have proved the non-formation of thiosulphate by the spontaneous oxidation of sodium sulphide solution in the air. The reverse is the case, however, and the tacit admission that sodium sulphide is converted at a certain stage of oxidation very largely into sodium thiosulphate was intended in the footnote. The toning experiments pointed to the conclusion that dilution alone, rather than the formation of hypo by oxidation, is the main cause of the too yellowish tones obtained by using a sulphide solution which, although freshly prepared from good material, is too dilute.

The writer desires to avail himself of this opportunity of stating, in explanation of the empirical and somewhat incomplete character of the "Experiments on Sulphide Toning," that the work was carried out some time ago as part of a plan—now abandoned—for an exhaustive examination of the methods of toning by means of sulphur, selenium, and tellurium. Much further photographic manipulation, together with both chemical and physical (colour) analyses, are probably necessary before it would be possible to understand fully the *rationale* of the tone-variation effects already known, and a theoretical discussion of these was therefore omitted.—Very truly yours,

E. R. BULLOCK.

Research Laboratory, Kodak Park, Rochester, U.S.A.

TRADE DISCOUNT ON MAWSON PLATES.

To the Editors.

Gentlemen,—We have received several complaints lately from customers stating that certain dealers are not allowing the maximum discount on the sale of our plates. We know that the majority of our friends selling our plates are careful to give the usual trade discounts.

In the interest, however, of ourselves, as well as of the buyer, we should be glad if you will give publicity to the fact that our discounts are the same as those applying to higher-priced plates.—Yours faithfully,

For and on behalf of MAWSON COMPANY, LIMITED,
DAVID BLOUNT, Managing Director.

Newcastle-upon-Tyne, August 26.

THE KODAK MANUFACTURING POLICY.

To the Editors.

Gentlemen,—In common with other professional photographers of the Kingdom, I received a day or so ago an "Announcement" from Messrs. Kodak, Ltd., stating that they were about to give up making glass plates, and were in future going to confine their attention to Portrait Film.

Had the announcement in question been confined merely to a statement of this change in the policy of the firm there would have been no cause for me to trouble you with any comments upon the matter. I should have just assumed that the management of the firm had decided that it could make more money out of film than out of plates, and I should have accepted the situation with what philosophy I could command, consoling myself with the thought that, should I require glass plates, there were other firms prepared to supply my needs.

But this announcement goes on for three pages trying to prove in the high-flown language so characteristic of the modern advertising manner that the glass plate has become old-fashioned and must be relegated to the past to which it now definitely belongs—"that the Eastman Portrait Film marks the beginning of a new era in photographic history—an era in which the plate is destined to become little more than a memory," together with much fulsome talk about "progress," and a picture of the Kodak Company leading the way throughout the ages, which I feel to be profoundly boring and unreal.

Now, as a matter of interest to the profession generally, I want to ask a question: Does the glass plate belong to the past, and are all those who, like myself, decline to give up using it, to be classed as "unprogressive persons who abhor change of any kind"? Personally, I think not. After making a most careful trial of the film, extending over some months, I find that I return to the glass plate more than ever convinced of its superiority and convenience, and I will give the Kodak Company the credit of being the manufacturers of the plate which I prefer to their much advertised film.

I am not saying for a moment that the Portrait Film is not a good film; it is, indeed, one of the best, but it has several very definite disadvantages and no amount of advertising will obviate these disadvantages. May I hazard the suggestion that the real reason why Messrs. Kodak are giving up the manufacture of plates is that they find it pays them better to import films from America than it does to employ British labour and to manufacture in this country. If this should prove to be the case, it appears to me to be a matter for very great regret, and not at all the subject for dithyrambic advertisement talk about "progress."—Yours faithfully,

HERBERT LAMBERT, F.R.P.S.

32, Milsom St., Bath.
August 30.

[In reference to the concluding paragraph of the above letter, we are informed by the Kodak Company that Eastman Portrait Film is made at their Harrow works.—EDS., "B.J."]

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. C.—We have never head of a developer supplied as "Creatol."

G. T.—We cannot see any difference between your two questions. In order to include the same amount of view on a quarter-plate as with a 19-inch lens on a whole-plate, the required focal length is half 19, that is 9½ inches, the quarter-plate being exactly half the scale (linear) of the whole-plate.

J. B.—There are no formalities whatever in obtaining copyright, registration having been abolished by the Act of 1911. The mere fact that you take the photographs without being paid by anybody to do so vests ownership of the copyright in yourself.

R. H.—Either of the lenses marked ought to cover a 15 × 12 plate. Of the two, we should prefer the Krauss, if in good condition. *F*/6.3 is quite large enough aperture for a lens of 20-in. focus; in fact, we think there is very little advantage in having a lens of this size of larger aperture than *f*/8. Except for subjects such as groups, and often for them, you will find yourself using the lens regularly at *f*/8 for the sake of depth.

An Old Hand.—We cannot undertake to make chemical tests of materials, but we have passed on your sample to a friend, who now informs us that it certainly is a sample of sulphite, but one, he considers, of low quality. Probably it contains less sulphite and apparently some acid impurity, so that, if you have to use it, you may perhaps be able to make it do by using more of it, and, at the same time, adding a little soda carbonate to the amidol developer, as found to be necessary.

A. J. F.—(1) If self-toning paper is well washed before fixing, or, better still, if it is passed through a weak bath of bicarbonate of soda before fixing, we think the results are just as permanent as P.O.P. Cases of impermanence of self-toning papers are chiefly due, in our opinion, to placing prints directly into the fixing solution which, thereby, is very often rendered acid. Therefore, we advise you to choose a paper which will give a good tone if thoroughly washed, or treated with bicarbonate, before fixing.

M. D.—Taking price into consideration, and also the fact that you only require to cover one-quarter of a quarter-plate, we think the best choice would be 152B, which could be easily fitted and would give excellent definition if in thorough condition. Another lens, also suitable for these midget portraits, is No. 156S, but this would not be of long enough focus to cover the whole quarter-plate. If you want to use the lens for quarter-plate negatives, No. 152B would be the better choice, and would be a fairly satisfactory lens for enlarging as well as for indoor and outdoor use.

Royal Patronage.—Can a photographer, who is engaged to photograph "a house-party group" amongst whom is the King and Queen, advertise, and use the term: "Under Royal Patronage."
Wallasey.

We think that if he advertises himself in these circumstances as having received Royal Patronage, he will come under the unfavourable notice of the Lord Chamberlain. From the brief particulars given it does not appear that he has received any royal patronage. The mere fact that the King and Queen were included in the group could surely not be considered as such.

C. Usherwood.—Unless we could personally supervise your work, it is difficult to say the cause of the veiling and inferior tones. But the most usual cause is over-exposure of the prints and development for a shorter time than can be given if you expose less. You should try cutting down your exposures, say to half or less, and then see whether you can get the required depth in the black prints by a longer period of development. As a rough guide, prints should be kept in the developer for at least 3 minutes. If you are developing in a less time than this, it is a sign that you are exposing too long. We should not use sulphide which has become liquid. It may be all right, but, on the other hand, it may have deteriorated. In any case, now it is liquid it is impossible to make up a sulphide solution of the proper strength.

W. H. C.—(1) If you are not familiar with making up the mercuric-iodide intensifier we advise you to buy it ready made, either in powder form from Mr. T. K. Grant, 89, Great Russell Street, London, W.C.1, or in "tabloids" from any photographic chemist. (2) We do not advise using M.Q. with caustic alkali, but if you must have a developer of this type, the following is a very good formula, particularly for use in cold weather, owing to the larger proportion of metol:—

Metol	60 grs.
Hydroquinone	30 grs.
Sodium sulphite	1 oz.
Sodium hydrate	120 grs.
Potass bromide	10-15 grs.
Water	15 ozs.

(3) We know of no method of restoring a negative which has received patchy stains from mercury intensification. The best thing you can do is to make an enlarged transparency from it, and work this up on the back with stump, and on a "Bildup" coating, so as to even out the patches of lesser density.

W. A.—(1) We do not think temperature of development has anything to do with it. The darkness of the renderings is no doubt due simply to the exceptional tanning of the complexions in conjunction with the use of an ordinary plate. You would do better with a self-screen plate and liberal exposure. (2) The usual plan of making embossed titles more distinctive is by the use of thin-metal foil, which adheres to the relief letters, and can be brushed away from other portions. You can obtain these foils through any dealer in embossing machines. (3) If the ordinary mercuric-iodide intensifier does not give you sufficient increase of contrast we should try more powerful means, for example, the Monckhoven mercury-cyanide intensifier, a very short action of which will give very considerable increase in contrast, often a great deal too much. (4) To a certain minor extent the definition of a complete lens suffers from the fact of construction allowing of the use of the separate elements as single lenses. But in practice this does not amount to a very great deal. Generally speaking, however, the greatest perfection in lens construction is reached when the whole objective is not convertible into separate lenses.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3201. Vol. LXVIII. FRIDAY, SEPTEMBER 9, 1921. Price Fourpence.

Contents.

SUMMARY

Mr. T. C. Turner sends a graphic description of the disaster to the R.38, of which he was an eye-witness, and of which he obtained the first photographs taken at close quarters on the Humber. (P. 537.)

Mr. Thomas Bolas, in an article on the Freund process of desensitising with potassium iodide, points out the characteristic peculiarities of this method, one of which is that bromide acts as an accelerator in the subsequent development. He gives practical instructions for the making of the iodide desensitiser and the subsequent developer. (P. 532.)

Mr. Harold Baker relates his experience in attempts to develop bromide paper according to a system. (P. 541.)

In a contributed article, Mr. R. R. Rawkins gives instruction in the making of bromide prints with a plain tint border, and insists on the use of a printing box specially for exposure of the tint surround. (P. 531.)

In a leading article we deal with the considerations which govern the selection of an appropriate height for the camera, both for landscape and interior subjects. Among the latter a low point of view will frequently effect a very great improvement. In portraiture also a low position of the camera renders the neck more gracefully, has the effect of shortening the nose and of causing the corners of the mouth to droop slightly. (P. 530.)

The repair of studio roofs with one or other of the semi-fluid compositions which are sold for application to zinc or lead roofing can be recommended as a means of preventing leakage which, otherwise, is pretty certain to occur as the result of the abnormally long spell of hot weather. (P. 529.)

M. G. V. Potapenko, in the concluding part of his paper on the theory and technique of light-filters, deals with the practical preparation of filters consisting of dyed films. He appends a list of 118 notable publications on the subject. (P. 534.)

The policy of the Kodak Company in discontinuing the manufacture of dry plates has prompted letters from several correspondents on the respective advantages of plates and cut film. (P. 542.)

A correspondent draws attention to the local trade to be done in views of buildings, which frequently are not published as postcards (P. 541.)

The programme of lectures to be delivered during the course of the exhibition of the Royal Photographic Society, which opens on September 19, will be found on page 538.

A recent communication from the Home Office describes the regulations which it is proposed to make relating to trades in which articles of celluloid or cellulnid material are manufactured or stored. (P. 540.)

The multi-view postcard or print may serve as an appropriate kind of advertisement for photographic studios. (P 530.)

The advantage of brilliant light when photographing still-life subjects or garden scenes in which much colour occurs is the subject of a paragraph on page 530.

A process of colour cinematography and methods of aero-photographic mapping are among the patents of the week. (P 538.)

EX CATHEDRA.

Leaky Roofs.

The long hot season which is now drawing to an end has probably loosened the putty in many studio roofs, and the first heavy rain is likely to reveal a goodly crop of leaks. There are some skylights which appear to defy all ordinary methods of rendering them weather-proof, but from an experience which we had last winter, we are able to suggest what would appear to be a permanent cure. It is, to use instead of putty or paint one of the plastic materials now extensively employed by builders to repair leaky slate, zinc and lead roofs. Our experiment was made with Matex, a semi-fluid composition, which was applied to every suspicious place in a studio roof with a palette knife. It appeared to run into the smallest cracks, and while in a few days it became fairly firm, it has not yet become hard enough to chip out of its grooves. There appears to be no necessity to remove any putty which is not actually loose, and there is no need to replace putty which has come away. There are several similar products, which would probably answer as well, and can be obtained from any builder's merchant.

* * *

Plates and Film.

As our correspondence columns show, the decision of Messrs. Kodak, Ltd., to discontinue the manufacture of dry plates, and thereby to mark their belief in the qualities of the Eastman portrait film as a negative-making material for professional photographers, revives a controversy which in the amateur field is of old standing. As we all know, reams of polemics have been filled during the past twenty years in debating the respective merits of plates and roll-film. Now that the controversy is transferred to the portrait studio, it involves questions on which opinions differ with equal sharpness, although the properties which distinguish the one type of material from the other for the purposes of the portrait photographer are of a different kind. It seems evident that one result of the action of the Kodak Company will be to provoke a more frank and heated discussion of the respective merits of plates and cut film in studio practice than has taken place hitherto. The Kodak Company have judged it well to challenge the merits of the dry plate, and, therefore, it is not surprising that users of the latter should be stirred in its defence. Without wishing to exhibit a bias one way or another in the discussion, it is necessary that we should correct a note which we appended to the letter of Mr. Herbert Lambert in our last issue. Although Eastman portrait film has been made at the Harrow works, the present supply comes from America. It is due to Mr. Lambert and also to the Kodak Company that prominence should be given to this correction. On the cognate point of employment of labour which is raised by Mr. Lambert, it is stated that the discontinuance of dry-plate manu-

facture does not affect the number of employees of the Company, but on the contrary will lead to a greater employment of labour in the future.

* * *

Light and Colour. There is an old proverb which says, "In the dusk all cats are grey," and the saying embodies a fact of great importance to all workers in colour photography by either screen-plate or three-colour processes. On looking at an ordinary street in sunshine one cannot fail to be impressed with the difference in colour contrast which exists between the lighted and the shadow sides. Photographing the same subject upon a dull day is virtually equal to working in shadow and the colour-rendering suffers accordingly. The same effect is produced in a less degree by working with a small lens aperture. Here again, the intensity of the light is reduced and the colour values are degraded, the defect not being avoided by prolonging the exposure. The best results from most still-life subjects can be obtained by working in the open air in the brightest diffused light obtainable, or in some cases full sunlight. It is never worth while making garden scenes in the evening, as the evening effect will be much more pronounced in the picture than it appeared to the eye when exposing.

* * *

Advertisement Postcards. A hint for producing an acceptable advertising novelty for manufacturers, boarding-house and hotel-keepers, may be taken from the view cards, composed of several pictures of a town, which are to be seen at most pleasure resorts. We have before us one issued by a photographer depicting his own premises. It consists of five views—an exterior, two studio interiors, the reception room, a dressing room, the entrance hall, and a workroom. These are fitted under a decorated cut-out mount bearing the name and address, which is photographed to the exact postcard dimensions. It is, of course, necessary to make a series of half-plate negatives in the first place, and these should be a source of profit independently of the cards, as they could be mounted for display at railway stations or other suitable places. If the cost of bromide cards be thought too heavy for large numbers, good collotypes could be substituted, or even half-tone blocks might be used. The latter, however, must be made through a very fine screen and well printed, or a cheap effect will be produced. Some of the trade printers are ready to make up and print the whole thing in bromide at a reasonable rate, if the photographer is uncertain as to his powers.

* * *

The Magic Lantern. The ordinary projection lantern, as sold for exhibiting slides, is a very useful addition to the apparatus of the amateur who works a small-sized camera, for not only does it enable him to show his work on a large scale upon the screen, but it enables him to make permanent enlargements from his small negatives, or such portions of them as are included within a four-inch circle. Most lanterns are provided with a lens of the portrait type, which is very similar, except that it is not provided with diaphragms, to those sold as "enlarging objectives." Should the field be too curved to give good definition at the corners, a cardboard stop fixed close in front of the lens will remedy this Should there be any leakage of light from the lantern body, it may be intercepted by hanging up a focussing cloth, with a circular hole cut in it, in front of the lens. Conversely, an enlarging lantern will answer perfectly for screen work if its construction allows of the slide being placed far enough away from the condenser to receive practically the whole cone of rays. If this cannot be done, an ordinary four-inch condenser may be substituted for the 5½ or 8½ one already fitted. This can easily be done by fitting the smaller condenser into a wooden block of the proper diameter.

THE HEIGHT OF THE CAMERA.

The height of the camera in relation to the object or view to be depicted is a subject which does not usually receive the consideration which it deserves. Many photographers practically work at a fixed elevation and adjust their subjects upon the screen, either by tilting the camera or by using the rising front, thereby neglecting a valuable aid to successful and artistic rendering.

It is granted that no particular elevation has advantage over others, the sole aim being to choose such a one as will suit the lines or proportions of the subject. In landscape, commercial work or portraiture a high or low view-point must be adopted according to the exigencies of the case; and it must not be forgotten that a difference in ground level between the camera and subject must be allowed for in reckoning the height of the camera. This may seem too obvious to need mention, but it is sometimes overlooked.

In landscape work the importance of objects in the foreground is to a great extent determined by the degree of elevation of the camera; and it may be well to point out that the effects of using the rising, or falling, front and of raising and lowering the whole instrument are widely different and must not be confounded. The former merely serves to adjust the view on the plate, while the latter has a very considerable effect upon the composition of the picture. This, perhaps, can best be explained by describing a photograph of a river scene taken with the lens less than two feet from the ground, the river bank being about six feet above the water level. At the eye level of a person standing, the edge of the bank is entirely omitted, and the view commences with an unbroken stretch of water, the buildings and trees on the further bank appearing flat and uninteresting. By lowering the camera some small bushes and plants are brought into sight, and serve to break up the monotonous surface of water, without materially altering the appearance of the distance or the amount of sky visible. If the camera front had been lowered to include the same amount of foreground, a large proportion of the sky would have been sacrificed and a much less pleasing view of the bushes obtained. On the other hand, if an unsightly iron fence had been in the foreground a higher point of view would have been the correct one to choose, and in certain positions might allow a foreground, invisible from the lower point, to come into view. A low view-point has the effect of foreshortening wide flat expanses, and this is usually beneficial to the composition.

When working on indoor subjects, either general views of interiors or single articles of furniture and the like, the height of the camera is of even greater importance, although it must be confessed that the photographer will here often find himself between two evils. A rather low position will minimise the "wide-angle effect" of table tops and chair seats which are near the camera, but at the same time it causes such near objects to obstruct the view of other things which it is desired to include. In such cases, the general effect must be considered and the distortion minimised by keeping such low objects as chair seats as far from the camera as possible, and bringing a small table or cabinet into the foreground. The flat surface in this case will be higher and the perspective less offensive. With single articles of furniture, as photographed for illustrative purposes, this trouble does not arise, and for these a lower position

with the camera kept perfectly level is to be preferred to using a higher one and tilting the camera, as is commonly done, particularly when the available space necessitates the use of a shorter focus lens than is desirable. There is one contingency in which a very high standpoint is advantageous in interior work, and that is when making flashlight or even daylight views in rooms containing a number of persons. In such cases it is necessary to choose a position from which all the faces are visible and, in the case of a dinner, the display upon the tables. Here the camera may be placed any height up to eight feet, or even more, from the floor and the lens pointed down, the camera back being brought to the vertical so as to secure both parallelism of the upright lines and to bring the nearer sitters into focus with a fairly large aperture. By this means it is possible to use a much larger aperture than if the camera were level, and the saving of flash powder or of time of exposure is considerable. When working by daylight the risk of movement is thus greatly reduced.

In portraiture, camera-height plays a very important part, and neglect of it militates against the success of the artist. The practice of placing the sitter upon a throne or platform, so generally adopted by portrait-painters, indicates a recognition of the merits of a low position for the eye. The reason generally assigned for this is that it gives a more dignified appearance to the sitter, while it has also been claimed that a more natural effect is produced when the picture is afterwards hung at a considerable height. The photographer will find it instructive to make duplicate exposures upon a life-sized plaster bust, altering nothing but the height of the camera, the lens being three feet and five feet from the floor respectively, and the head being in the position usually occupied by that of a sitter. Upon comparing prints, many noteworthy differences will be found. At the 3-feet elevation the neck will appear longer and more graceful, being more or less clear of both shoulders, the nose shorter, and the mouth more turned down towards the corners, than is the case with the picture taken at five feet. Lowering the camera is, of course, equivalent to raising the sitter as the painter does. Some very successful portraitists prefer to take bust pictures while the sitter stands, which, of course, comes to the same in the end, but the risk of movement, now that the head-rest is abolished, prevents many from attempting to do this.

It may be contended that as far as the features are concerned the same relative positions between the lens and the face of the sitter can be obtained by slightly inclining the head forward or backward. There is some truth in this, but such inclination must alter the pose of the head and neck, as well as the lighting, and the general effect will not be so good. A common mistake in taking full-length figures, where the lens has to be raised to the height of the sitter's breast, is to give an excessive tilt to the camera, so as to include the feet and foreground; or, failing to obtain sufficient tilt, to lower the camera. The proper course is to work at the proper height, to tilt slightly, and then to centre the image by lowering the lens board. It must be remembered that in any case, and more especially with a tall sitter, the lens is always in a relatively low position with a standing figure.

BORDER PRINTING ON DEVELOPMENT PAPERS.

A GREAT deal of the work turned out by high-class photographers consists of prints made on development papers (mostly of the gaslight type) with a faintly printed border surrounding the picture. At first sight the effect appears to be obtained by multiple mounting, and the whole production has a distinctive appearance. I am inclined to think that this style will become quite a vogue amongst the photographers who do a high-class business, but it is neither suitable nor desirable for general adoption by other photographers. The prints are generally made on card thickness or double-weight papers considerably larger than the negative—12 x 10 for whole-plate negatives and 9 x 7 for half-plate negatives.

The Cosway borders had a run some years ago, but the results were too ornamental and detracted considerably from the photograph itself. Personally, I think the border should be quite plain, and printed lightly with the edge of the photograph softened into the border so that there is no line or shadow showing.

The Apparatus.

Border printing sets can now be obtained commercially in a variety of stock sizes. To those who are not familiar with border-printers I may say that a set consists of two parts. One is a mask upon which the negative is placed, and the other a framework of celluloid upon which is fixed the part cut out of the mask. Small right-angle "feed" stops are fixed so that registration shall be correct. The negative is placed film up on top of the mask, adjusted the printing paper "fed" to the stops, and exposed. The paper is then transferred to the celluloid tinter part, "fed" to the stops and exposed. If the "feeding" has been correctly done the resulting print should not show any join or shadow, but I have heard several photographers complain that the "feed" stops are too small and not raised sufficiently in some of the commercial sets.

Photographers can easily make their own border-printers provided they can cut masks true. I prefer the home-made variety, and make a point of fixing prominent right-angle "feeds" the whole length and breadth of the paper. To those who intend to make the border-printers I would say that everything is easy with the exception of fixing the "feeds" in the correct place on each part. One good method is to use pin-pricks and fix the stops to the holes. Another is to print a piece of P.O.P on both the parts, join by transmitted light, and trim together. Other methods may occur to the practical man. It must be understood that with a properly made border set there is no special skill required to produce perfect results, but the fact that the image cannot be seen until developed makes it imperative for the "feed" stops to be correct and foolproof.

Printing the Border.

The object of this article is to deal with printing the borders and not to describe how to make the apparatus. To those who are desirous of introducing border-printed photographs let me say that one essential to success is to make a special exposing light-box for exclusive use with the celluloid tinter part. The illuminant should be such that an exposure of not less than two seconds (four seconds for preference) will produce upon full development a light grey border. The exposure would seldom vary (excepting with different papers or batches) and the border part could be exposed by a junior assistant, who could do as many as required and place them in a light-proof box (all one way up, of course) for the printer who exposes the negatives. It is asking for trouble to use the same box and printing light for both negative and tinter unless some definite method be adopted of screening the light when exposing the tinter. The exposure would be so quick that a big margin of error is possible, and instead of obtaining a light

grey border we should get a border like a funeral card. In exposing borders as above for stock it is not advisable to do more than is likely to be required for three days' work, as I have found that with some papers the latent image deteriorates to such an extent as to almost disappear, especially in damp places or in damp weather. The exposures may have to be varied under special circumstances, such as printing the portrait part from a hard negative, which necessitates considerable over-exposure and arrested development to produce a soft harmonious result. This short development would naturally affect the border part and therefore the exposure through the tinter should be increased. The same remarks apply to prints made on development papers that give warm-blacks by over-exposing.

Printing the Portrait.

In printing the portrait part, the negative is placed film up on top of the mask opening and adjusted to suit the subject. There is very little to play with if the mask is only a quarter-of-an-inch smaller all round. For half-plate negatives I use a $5\frac{3}{4}$ x 4 opening. Some negatives have rather wide clear-glass rebates, and if this rebate comes within an eighth of an inch of the mask opening the light will creep under and cause a shadow line to appear on the border. The remedy is to block out the rebates with an opaque strip, or reduce the rebate ledge in the dark slide of the camera. Another way to avoid shadow lines is to permanently fix (by the top edge only) a thin opaque mask a trifle larger all round than the negative mask so that the negative can be slipped under this special mask to protect the clear-glass rebate.

Printing from Films.

If film negatives are used it is necessary to fix permanently a piece of clear glass to the mask. This glass should be at least half-an-inch larger all round than the mask opening, and must be fixed on top of the opening. The film negative is then placed on this glass and fastened temporarily with gummed strips at, say, two corners. The usual thickness of glass used for negatives is just sufficient to give that very necessary diffusion which the edges of the mask give by being in contact with the "glass" side of the negative.

Helps to Correct Registration.

The best type of border printer is that which has raised "feed" stops because the printing paper used may not be cut absolutely true, and correct registration can be obtained by making a point of *always* "feeding" the paper to one side and simply allowing the top to touch where it will. This must, of course, be done with both mask and tinter.

The pressure pad can be made from thick cardboard or three-ply wood covered with felt. When the printing paper is "fed" as described, the pressure pad can be slid on the back of the paper up to the feed-stops, and the grip given by the felt will be sufficient to ensure correct feed. Paper that is inclined to curl is difficult to handle, but a good pad with felt grip will help to prevent any bulging.

Printing Names or Titles.

The best place to fix a negative or positive of, say, the photographer's name is on the tinter part, as the exposure of this part is constant. If a facsimile of a signature is required it is an easy matter to first write the name in indian ink and then to copy it on a celluloid film. This can be fitted in the tinter part by cutting away some of the opaque paper outside the actual tint at a spot chosen and fastening the film negative to the opening with adhesive. It may be necessary to add one or two additional thicknesses of clear celluloid to the *back* of the little opening to ensure perfect contact.

R. R. Rawkins.

DESENSITISING WITH POTASSIUM IODIDE. FREUND'S METHOD.

Now that so much attention is being given to Lüppo Cramer's method of desensitising so as to allow of comfortable observation in a good light during development, it may be well to look back on an old, much neglected, and very much misunderstood or misrepresented method by which a similar end can be realised, but without the disturbing element of stains or dyes.

The method in question, that of Freund, merely requires a weak solution (1 in 25) of potassium iodide, in addition to the usual chemicals for development; and development can be carried out in a white light such as one has in an ordinary room; in fact, by such a light as will serve for reading a newspaper or book. The absence of obscuration by a dye is a distinct advantage when careful watching is desirable, as in making the triad of negatives for heliochromy.

Freund devised his process some fourteen years ago, and full working details are given in his German patent specification of 1908 (No. 213,775), but I have not traced any parallel British specification. The process consists in soaking the exposed plate for about two minutes in a 4 per cent. solution of potassium iodide, whereby the unexposed particles of silver bromide are superficially or partially transformed, or pseudomorphed into silver iodide; while the fully exposed particles appear to undergo little or no change. The plate so treated develops in the dark-room much or nearly as an ordinary plate would develop, or as if no bath of potassium iodide had been used, but there is this advantage: Once the developer is well over the plate the dish (not a glass-bottomed dish, unless protected) may be taken into moderately intense daylight, and the development can be minutely watched or carefully studied without fear of fogging. Bromide of potassium added to the developer acts as an accelerator, and tends to softness, and Freund mentions a developer for ordinary use which contains one-sixtieth of potassium bromide; but if the utmost acceleration with softness is required, the developer may be nearly saturated with potassium bromide, the extra dose being added towards the finish of the development.

All the above will be fully understood if it is remembered that silver iodide, whether exposed or unexposed, is almost unaffected by such weak alkaline developers as are used in ordinary photographic practice, while the developability of the latent image is scarcely or not affected by the potassium iodide, excepting so far as too prolonged treatment with the iodide or the use of an over-strong solution of the iodide may appreciably iodise and weaken the latent image.

While the iodide of potassium solution covers the exposed plate, light will obliterate or destroy the latent image: the action in this case being analogous to the essential feature of Bayard's pre-Daguerrean process, the chemistry of which process is very admirably illustrated and explained in lines 17 to 28 of col. 1, p. 158, of Volume IV, Watts's "Dictionary of Chemistry," new edition, 1888 to 1894. The article in which the above is contained is on photographic chemistry, and is by the late Professor Meldola. It is pointed out that in the system which consists of:—(1) Exposed gelatino-bromide film, (2) potassium iodide solution, the potassium iodide is the photolyte and the exposed film the sensitiser; so, the photolyte being uncoloured, it is by no means surprising to find that

the red light of the dark-room may have in this case a very considerable action, hence the potassium iodide should act in complete darkness—or in a remote corner of the dark-room. Another source of over-iodising and obliteration is the use of almost chemically pure iodide of potassium. The chemically pure iodide of potassium is so sensitive to the combined action of light and moisture that, as seen, sold and handled, it is invariably more or less brown from the presence of free iodine, and its solution in water often becomes very definitely brown. This solution will not only over-iodinate the plate as a whole, but will partly or entirely destroy the latent image. The remedy is to use the so-called medicinal potassium iodide, which contains free alkali and remains white, or to add an alkali to the pure iodide, as described in the practical section below.

Potassium Bromide as an Accelerator in the Developer.

If all conditions are satisfactorily realised, a state of things by no means difficult, a fully vigorous and well-gradated negative is obtained without the use of bromide in the developer, but if there is over-iodination a hard negative recalling the result of under-exposure is obtained. A partial remedy for this is to use potassium bromide very freely in the developer: the potassium bromide acting as an accelerator and producing the weak, thin and often fogged negatives which, in the case of ordinary work, result from excess of alkali in the developer, and the non-use of bromide.

Thus the effect of bromide is precisely the reverse of its effect in ordinary work, this being quite easy to understand when it is remembered that the function of the soluble bromide in Freund's process is to partly de-iodinate the plate by the "action of mass." In this reaction we have a specially interesting example of one of the many notable inter-actions of silver halides and alkali halides.

Early Misunderstandings as to the Freund Method

Most, and perhaps all, of the troubles incident to the early history of the Freund method are, I think, traceable to a misunderstanding of the function and effect of the soluble bromide in the developer.

Take, for instance, the account of the method which is to be found on p. 1427 of "Die Photographische Industrie" of October 20, 1909, an account which appears to be the source of inspiration of most of the notes and articles which have appeared in the English and French publications. To Herr Freund's statement that a very large dose of bromide in the developer acts as an accelerator, "Die Photographische Industrie" appends no word expressing doubt; but the course taken reminds one of the legendary Sacristan:—

"The Sacristan, he says no word that indicates a doubt,
But he puts his thumb unto his nose, and spreads his fingers out."

The "(? ?)" which follows Herr Freund's statement may be regarded as a journalistic or technical equivalent of the Sacristan's gesture.

No wonder, then, that on p. 13 of the 1912 edition of Cassell's "Cyclopædia of Photography," under the heading "Aktinal" (the iodide solution was sold under this name) is to be found a statement that the "developer is fully restrained with potassium bromide."

Important Researches by M. Coustet.

The one carefully studied and serviceable article on Freund's method which requires special notice is that by M. Coustet, and it is to be found on p. 197 of the "British Journal" of March 15, 1912; but M. Coustet's comments and experiments on the Freund method are rather likely to escape notice and indexing, as this matter is supplementary to an article on development in daylight after fixation.

M. Coustet carries the method several stages farther. He considers the possibility of operating by adding the soluble iodide to the developer (soda sulphite and diamidophenol) without the use of a soluble bromide, and although the indications appear against this course, the secondary outcomes are highly important. In this case the iodination does not travel through the film towards the glass side so fully as when the separate iodising solution is used, and M. Coustet was led to observation of the depth action, or extra density of image in the lower strata. Here we may have a gradual change towards the ordinary condition, and a region may exist where bromide in the developer may be much weakened in its accelerating action; or possibly in a thick stratum the turning point may be passed and the bromide may function slightly in the lower strata of a thick film, in its usual *rôle* of a restrainer.

To the experiments and comments of M. Coustet I owe suggestions which made the Freund method really satisfactory in my hands.

Practical Instructions for the Freund Method of Daylight Development.

The preceding matter should be read and understood, and thus the present section may be made concise in some parts.

Plates.—Gelatino-bromide, slow or rapid, colour sensitised or otherwise. Bromo-iodide plates are less suitable, but may be used if increased exposure is given, and a tendency to thin images is tolerated.

Exposure.—Usual or ordinary exposure for bromide plates. Bromo-iodide plates may require one and a-half to twice the usual exposure. If the iodising solution contains even a mere trace of free iodine, there will be partial destruction of the latent image: so, whatever the exposure, results will be unsatisfactory.

Iodising Solution.

White medicinal potassium iodide	1 oz.
Water	24 ozs.

Somewhat greater certainty is realised by using the "pure" potassium iodide of "analytical reagent" standard, but the free iodine must be neutralised (see above, under the heading "Important Researches by M. Coustet"), or if at any stage the potassium iodide solution shows the faintest trace of brown colour from the presence of free iodine, the following routine must be followed:—To the above 25-oz. batch add 5 grains of crystallised sodium carbonate, if the brown tint is so obvious as to be seen at a glance, or 2 grains if faint. The carbonate of soda acts slowly, and requires warmth, as by placing the bottle in a saucepan containing cold water, raising the temperature to near the boiling point, and allowing to cool. By repeated treatments, if necessary, and in this way every trace of brown colour must be eliminated, the bottle being placed on a sheet of white paper for observation, and it must be remembered that the action of light may renew the brown tint, but restoration in this case is by warmth alone.

Iodising the Exposed Plate.—Ordinarily two minutes in *complete darkness* or in a dark corner of dark-room. Longer for cold weather or hard coating, less for warm weather or soft coating. Rock dish whole time.

Signs of Over-Iodising.—Slow development, hard picture. Bromide required in developer as accelerator.

Signs of Under-Iodising.—Rapid development, soft picture, fogging in the weak daylight. Addition of iodising solution acts as a restrainer.

Washing after Iodising.

Three or four changes of water in dark-room. Avoid even red light during the washings, or until the developer covers the plate. Failure to wash, or a short washing, is equivalent to adding a restrainer.

Developer.

Purest (A. R. Standard) crystallised sodium sulphite	1 oz.
Crystallised sodium carbonate	1 oz.
Water	4½ ozs.

Crush the salts in a mortar, add the water, and grind till dissolved. Then add:—

Hydroquinone	45 grs.

Measures about 5½ ozs. Will keep good for years in full and well-closed bottles. Suited for most aspects of work. Seldom requires the addition of bromide. Dilution undesirable.

Development.—Not in the direct stream of light from a window. Glass dish to be preferred. In light tight case with lid. The crux of development is the condition of the deeper strata, so occasional glances are required by lifting out. The coated side should be turned towards the window during inspection. The iodising solution acts as a restrainer: one-twentieth the volume of the developer and over. Potassium bromide acts as accelerator: of a 10 per cent. solution add one-tenth or over. If practicable, it is better to avoid the use of potassium bromide. See mention under heading "Important Researches by M. Coustet."

Fixation.—After washing, a plain "hypo" bath, 1 to 4 of water, is used for fixation, and rather more time is required than in the case of plates containing no iodide. All the usual considerations apply. For example, fixation in the dark-room or in a subdued light, thorough fixation and, perhaps, second hypo bath after plate appears clear, testing the purity or efficiency of chemicals. The worker who is careful in these matters is likely, on the whole, to do better and more uniform work than one who is lax. Similarly, one who realises standard activity of solutions by using but once is likely to fare better than one who uses solutions many times; but it may be mentioned that the iodising solution may be used many times, and that the above-mentioned developing solution has a like quality in a very pronounced degree; but to realise the many merits of this developer the purer grade of sodium sulphite must be used.

Somewhere I seem to remember having seen a suggestion that potassium cyanide should be used for fixing in the Freund method, but I regard this as undesirable from several points of view, although there are exceptional cases in which cyanide fixing may perhaps be desirable for gelatine plates, as, for example, when a weakening of the fainter tones is desired.

Much more might be said about the Freund method, but it is hoped that enough has been said to call more general attention to it—a much neglected method—so that it may take its due place in photographic practice.

THOMAS BOLAS, F.C.S., F.I.C.

THE THEORY AND TECHNIQUE OF LIGHT-FILTERS.

[The following is an important paper on the principles of the action of light-filters and on the practice of their preparation and use. It is the work of a Russian physicist, M. G. V. Potapenko, and was first published in the Journal of the Russian Physical and Chemical Society (Chemical Section) 1916, vol. 48, p. 790. We owe the accessibility of the paper to Dr. C. E. K. Mees, by whom the translation from Russian has been made. Dr. Mees while rendering the text into English, does not thereby wish to imply his agreement with everything contained in it. He has refrained from exercising a translator's right of commentary except in one or two instances which particularly call for correction. The fact that he has made the translation and given us the opportunity of publishing it, may be taken as an indication that he regards the paper as a contribution to the literature of light-filters of exceptional value.—EDS. "B.J."]

(*Concluded from page* 524.)

For yellow compensating filters a most useful dye is rapid filter yellow, prepared by König[42] (Höchst Dye-Works), and the six filters given by him are included in the following table :—

No.	Dye Concentration.	Edge of Curve.	Filter factor.
1	.07H	415$\mu\mu$	1.5
2	.15H	425$\mu\mu$	1.8
3	.29H	435$\mu\mu$	2.0
4	.59H	450$\mu\mu$	3.0
5	1.18H	470$\mu\mu$	4.0
6	2.37H	490$\mu\mu$	6.0

In the last column of the table is given the factor of the filter, *i.e.*, the increase in the exposure required when the filter is used with plates sensitized with pinachrome, whose spectral curve is given in Fig. 9.

In Fig. 10 are shown diagrammatically the absorption curve given by these six filters, and it will be clear at once that none of them correspond exactly to the compensating filter required for correct translation of colour values in the making of the negative.

These filters, are, however, of considerable importance in landscape photography, since, thanks to their absorption of the violet light, they increase the constrast of the photograph, and the clearness of detail in the scene. In Grebe's classification they are placed in a separate group and called "contrast" filters, regardless of the fact that from the point of view of their absorption curves they belong to the group of compensating filters.

We have not yet considered the degree of precision which can be obtained in the production of a given absorption curve, or how far we can expect to repeat the preparation of a filter of a given constitution. This will depend both on the instability of the dyes and on the effect on their absorption curves of small amounts of impurities in the gelatine, and even on changes occurring as a result of keeping the dye solutions. In order to deal with these questions we must consider the technique of the preparation of filters.

The Preparation of Dyed Films.

Filters may be divided into those of gaseous, liquid or solid form. The first are very rarely used, having first been employed by Cornu, who used bromine vapour, which H. P. Peskoff recently utilised for the preparation of an ultra-violet filter.[43]

Liquid filters have been more widely used, thanks to their simplicity and to the variety of coloured solutions which are available.

Solid filters, as we have already said, for a long time were used only in the form of coloured glasses, and it is only recently that these have been replaced by thin films made from solutions of dyes in collodion, celluloid or gelatine. Such films are very cheap, convenient in use, and can be obtained more easily than the various forms of glass-walled cells required with coloured solutions, which must be made with extreme care if they are not to affect the optical definition. The most accurate and technically perfect appear to be films made of gelatine, the preparation of which we will now consider in detail.

In practice such films are most conveniently placed between two thin glass plates or collodion films, which will protect them from damp and injury.

Any transparent emulsion gelatine is suitable for making filters, but the hard gelatine which dries more quickly and gives a firmer film when set is easier to use, and is therefore to be recommended for initial trials; the softer varieties make it possible to obtain after some practice a more even coating and a clearer surface. A preliminary soaking of the gelatine in an alum solution hardens it and raises the melting point. Recently the firm of Meister, Lucius & Bruning have placed on the market special gelatine of great transparency for making filters.

The melting point of gelatine, as was shown by Dr. Lohse,[44] is not definite, and does not appear to be constant, but for 8 per cent. solutions it may be taken as from 30 deg. to 32 deg. C. With lower concentrations the melting point falls, and rises with greater concentrations.

Gelatine solutions set at temperatures below 30 deg., and the difference between the melting and setting points for most emulsion gelatines is 8-10 deg.

In making filters a weighed quantity of the gelatine is first solution of bromide instead of water. After washing, the gelatine

42. König, *Das Arbeiten mit färbenenff, Platten.* Berlin, 1909, p. 41.

43. H. P. Peekoff, J. Russ. Chem. Soc., 1915.

44. Lohse, Phot. Archiv., 1880, p. 50.

being continuously kneaded with the hands to ensure the removal of soluble salts. Henderson[45] recommends the use of a 1 per cent. solution of bromide instead of water. After washing, the gelatine is transferred to a weighed beaker, where the required amount of water is added. The temperature is raised to 30-35 deg., solution being aided by stirring with a glass rod.

Frequently the gelatine contains a small quantity of fat which produces on the surface of the filter small transparent spots like pinholes. The fat can be removed by keeping the gelatine solution in the liquid state for two or three hours without increasing the temperature. In this time the fat separates from the solution and appears on the surface in a large spot. A longer keeping of the warm gelatine cannot be recommended since otherwise it will set badly, an effect which Eder[46] ascribed to decomposition. Without shaking the solution it is allowed to set, and after warming the outside of the beaker the set mass is removed and the top and bottom layers to the thickness of 5 10 mm. are cut off with a horn knife.

The remainder of the gelatine will be perfectly transparent, and can be used for making filters. The gelatine must now be dissolved again, warming it to the former temperature, and it is then filtered through flannel or chamois leather just as thick liquids are filtered (i.e., by the aid of suction or a filter press).

König and Hübl[47] recommend the use of 5 per cent. solutions of gelatine, but it is much better to employ a somewhat greater concentration, about 8 per cent. This gives better results, since drying proceeds more quickly, but owing to its thickness it flows over the surface of the glass more slowly, so that its use requires some practice. Many authors advise the use of still stronger solutions containing 10—12 per cent., which set still more quickly, stating that when more liquid solutions are used there is sometimes a dulling of the surface, which is ascribed to the separation of grease from the solution.[48] If difficulties are met with as a result of using thick solutions, thinner ones should be substituted for them.

Sometimes it is advisable to add alcohol to the dye solutions, but only in small quantity, up to 5 per cent.; this improves the surface of the film, increasing its polish. The addition of the alcohol to the gelatine also assists in preserving it from decomposition, which affects setting, and also leads to curling and wrinkling of the film.

To prevent the film cracking, which occurs especially with high concentrations of dye, glycerine is sometimes added, which adds to the elasticity of the film and diminishes its contraction when coated on the glass. This contraction can easily be observed from the bending which it produces in the glass plates on drying.

The extent of the bending produced can be seen from the fact that an 8 per cent. gelatine solution coated on a glass of 1.12 mm. thickness to the extent of 7 c.c. per 100 square c.m. will produce a curve having a radius of from 14,889 to 19,471 mm.[49] The shrinkage also results sometimes in the cracking of the film. While making a filter from Crystal Violet in a concentration of 3.0 H. coated on a plate 40 by 60 cm and 1.0 mm. thick, the curvature was easily visible as a result of improper drying, and the surface of the film was covered by a network of cracks.

In such cases it is necessary to add to the gelatine about 3 per cent. of glycerine, but this diminishes the stability of the dyes, so that they are liable to fade rapidly and thus render the filter useless.[50]

The addition of acid or alcohol to the solution has sometimes a considerable influence on the dyes, changing the character of their absorption curves. This is often the cause of considerable difficulty in obtaining duplicate results. The gelatine solution prepared as above and carefully filtered is ready for use, and after the addition of the dyes we may proceed to the most difficult part of the work, the coating of the filters. Experience has shown that the best results are given by using 7 c.c. of gelatine solution to 100 cm. of filter surface.[51]. The thickness of the film obtained in this way will not exceed .04 mm. Before coating, two solutions must be prepared separately, the dye solution and the gelatine, which when mixed together will give the required concentration and colour. If the above-mentioned quantity of dyed gelatine is used for coating, each square metre will require 700 c.c., and consequently the following solutions may be used:—600 c.c. of 9 per cent. gelatine and 100 c.c. of dye solution, containing as many grams of dye as the required filter contains in Hübl units (grams per square metre). When the two solutions are mixed they will clearly correspond to about an 8 per cent. solution of gelatine. We may repeat that throughout the work the temperature of the gelatine must not exceed 35 deg. C.

Before coating, the glass must be carefully cleaned from dust and grease. The glass may be treated with boiling water, dilute nitric or sulphuric acid or spirit. We obtained the best results by cleaning the glass with a hot soda or borax solution, and then polishing with alcohol.

If the surface of the glass is not perfectly clean and grease spots remain on it, the film is uneven, this being particularly observable just after setting. The greatest number of failures are due to insufficient cleanliness of the surface, to which the greatest attention should be paid. The coating is carried out in two different ways, according to whether the film is to be stripped from the glass, or whether it is to remain on it. In the latter case the glass must be of very good quality, and should not be thicker than 1-½ mm., in order that its absorption for light should be as small as possible. If it is intended to strip the film from the glass its surface should first be coated with a 3 per cent. solution of collodion containing 1 per cent. of castor oil; this is then coated with the necessary quantity of dyed gelatine, and after drying it coated again with the collodion. The film is then cut through at the ends and lifted from the surface of the glass. Such a film, however, has not much strength, and owing to its thinness is easily torn. To obtain a stronger and thicker film the following procedure is used:—The collodion-coated glass is first coated with an undyed gelatine solution prepared as follows:—

200 c.c. of 12 per cent. gelatine solution warmed to 40 deg., to which is added

5 c.c. of acetic acid.
5 c.c. of glycerine.
70 c.c. of alcohol.

After drying, this is coated with collodion on which is again coated the dyed gelatines, and this is finally protected by another coating of collodion. Such a film will be strong and very flexible, while its thickness does not exceed .2 to .3 mm. The thick coloured films found in commerce are made in this way. A formula given by Fleck[52] is as follows:—

To a solution of

Alcohol	70 gms.
Ether	30 ,,
Collodion	4 ,,
Castor Oil	2 ,,

Add the required quantity of dye and coat in a thick layer (5 to 10 mm.) on a carefully levelled glass plate. The plate is placed in an electric oven and dried at a temperature of 50 deg.

To aid in stripping the films it is sometimes recommended that the glass should be prepared with talc or a solution of wax, but this often causes failures, as the gelatine coats badly on such a surface, and with small filters an even coating cannot be obtained, the centre being thicker than the edge.

The coating is done as follows:—The required amounts of gelatine and dye are mixed in the proportion of 1 : 6 and are warmed on a water-bath to a temperature of from 40 to 45 deg. A calibrated pipette is also warmed, this being used to measure out the required amount of solution. The solution is then flowed on to the middle of the glass, which has been levelled carefully and is spread over the surface. Two or three cm. above the glass is placed a cover to protect it from dust, this being preferably a second glass, though a piece of cardboard can be used. When the gelatine is set, the filter is placed on edge in a drying cupboard until completely dry.

The solution must not be heated above 45 deg., or the setting power of the gelatine may be affected. Insufficient heating also introduces difficulties, since the gelatine is difficult to coat, and is sometimes covered with characteristic damask-like markings. The room should be rather warm, about 20 deg. C. The glass must not be warmed, since this cannot be done evenly, and thus affects the cleanliness and evenness of the film. Failures are often caused also by shaking the glass in order to cause the solution to spread over the surface. If the solution spreads badly it may be ascribed to inferior gelatine, and the coating can be improved by the addition of a little acetic acid.[53] If, on the other hand, the gelatine

45. Henderson, Phot. News, 1885, p. 303. (This is probably a misunderstanding; Henderson was discussing the use of gelatine for making emulsions, not filters.—Translator.)

52. Fleck, Phot. Chronik 1901 p. 366.
53. Eder, Phot. Corr., 1896, p. 483.

sets slowly and unevenly, it is often due to decomposition, since the gelatine solution must not be kept too long; it is also possible that too soft a gelatine has been used which could be improved by treatment with alum solution. Such in brief is the whole process for the making of light-filters. It will be seen that it is quite simple, and that with some practice failures should be rare.

There is another method which may be called "the bathing process." In this the glass is first coated with undyed gelatine forming a thin film over its surface. After this has been dried the glass is immersed in the dye solution, where the gelatine becomes coloured to the required degree and is then completely dried. In this process the colouring is often uneven,[54] and it is advantageous only because of the possibility of using ready-coated gelatine, such as a fixed out photographic plate of which the gelatine film can be used for dyeing.

Dyes for Light-Filters.

The selection of the dyes to be used in making light-filters is of the utmost importance. We have already seen that not all dyes can be used in dry films, since many of them crystallise out during the drying of the gelatine. In addition to the fact that many are unstable and fade rapidly, only a few have sharp enough absorption curves to give satisfactory filters. These considerations, as we have already said, led König[55] to select about 40 special dyes, of which 18 were investigated by Von Hübl, who measured their absorption curves with the utmost precision.[56] The most complete series of investigations of the absorption spectra of dyes is due to Formanek,[57] but his results can only be used as preliminary indications, since the absorption curves of dye solutions which were measured by Formanek rarely agree with their absorption in dry gelatine films.

The part played by gelatine has not yet been definitely settled, but its influence on the absorption curve of a dye may be considered to be demonstrated; this was confirmed by Monpillard[58] and Von Hübl[59], who ascribed it to the influence of sulphite present in the gelatine. The prolonged washing of the gelatine in clear water previously recommended was for the purpose of removing these salts. The reproducibility of our curves previously referred to may therefore now be considered as dependent on the purity of the gelatine and the accuracy with which its solution is made.

The general character of the absorption curve does not vary when different kinds of gelatine are used, but the numerical value of the co-efficients vary within a few per cent., and greater accuracy cannot be expected until the influence of the gelatine on dyes has been more completely investigated. In coating filters it will be observed that the colour of the dry film and of the undried gelatine after setting is never the same. It is possible to some degree to form an idea of the way in which the drying should affect the absorption curve changing its position in the spectrum to some extent; this effect is often called the shifting of the curves. More careful measurements show that the character of the curves is also not entirely unchanged, and that they are frequently deformed to a surprising extent, which suggests that processes of unknown nature take place during the drying of the film.

A question of some importance is the effect of the mixing of the dyes on their absorption curve; changes might arise from reactions between the materials, and it might be expected that the absorption co-efficient of the mixture would be a complex function of the co-efficients for the separate dyes. For solutions of dyes, a case has been given by Plotnikoff.[60]

In the simplest case the dyes are indifferent to one another, and equation (5) can therefore be written in the following form for a mixture of dyes in a dry form:—

$$I = I_0\, 10^{-(c_1 c_1 + c_2 c_2 + c_3 c_3 + \ldots\ldots)}.$$

In his investigations Hübl[61] did not notice any departure from the law expressed in this formula, and accepted it without qualification. From our own measurements the formula is also satisfactory within the limits of accuracy discussed previously, but the measurements made on coloured films on the dry film up to the present time are so limited that a definite decision on the question must be left to the future.

G. V. POTAPENKO.

THE AIRSHIP DISASTER AT HULL.

MR. T. C. TURNER, of Regent House, Anlaby Road, Hull, kindly sends us the following vivid description of the disaster to the R38 dirigible, of which he was an eye-witness. It will be seen from his account he was the first photographer to reach the wreck of the rear part of the airship on the water, his exposures being made at close quarters some time before those of any other photographer's. Moreover, his account is of great interest, since it corrects some of the imaginative "descriptions" of the disaster which have appeared in the newspapers. Mr. Turner's notes should have appeared in our last issue, and were despatched from Hull in time for inclusion in our issue of last week. Unfortunately, through a delay in postal transmission, which appears to be a fairly common feature of the present high-priced postal facilities, it failed to reach us until seven or eight hours after going to press.—EDS., "B.J.")

The studio was about to be closed when I heard the loud roar of an airship approaching from the north. For the moment I did not hurry to go down into the open, and, as projecting walls shut out my view to the north-west and north-east, I could only obtain a limited view of the sky due north. But as the airship seemed to be quickly getting overhead I hurried down to the front of Regent House, which faces due south and the Humber.

I was just in time to have a magnificent view of the immense vessel sailing due south-east after having just passed, presumably, over my house in a sharp curve from the north-east, as I noted the people outside were pointing upward in that direction. She was, apparently about 1,200 or 1,500 ft. up, and was moving fast. The weather was fine, and sunshine bathed everything around in glorious light; only in the upper strata was there fine mist in patches. The airship at moments passed through these patches of mist, but they were not sufficiently dense to obscure the view of it, only thick enough to make the chances of a perfect negative a little doubtful.

From the moment she passed over the house to the final catastrophe seemed to be but a minute or slightly more. As I look into the sky opposite, I still shiver with the horror of what happened. The glorious vision of beauty and movement suddenly and quite noiselessly parted well behind the middle, and to my amazement I saw the front portion for some seconds continue its course, while the rudder end followed more slowly, and, inflated, I suppose, by the draught, began to descend, but quite in its ordinary shape like a long cup with its open mouth towards the Humber. It was an amazing sight to see the two portions of the gigantic vessel separately moving in the sky and both descending. It occurred to me that if they were far enough to the south they might both safely reach the water. Suddenly, however, the front portion took a severe angle, and then commenced a terrific nose dive. With increasing speed and an awful twisting movement, she disappeared from my sight behind the houses which stand between my place and the Humber, which is from a quarter to half a mile away.

Four seconds elapsed, and then two frightful bursting reports shook the city. I just had time to jump away from a huge sheet of glass next door which shivered and fell to atoms. It was as if the gas, liberated on reaching the ground or water, had mixed with air and exploded, for it was very different from the more localised shock of bombs in the days when we were too horribly familiar with enemy airships, and would have rejoiced to see such a catastrophe.

Frightfully excited, I picked up my focal-plane camera, which ever since the days of the war I have always kept loaded ready for emergencies, and rushed with one of my sons to the river front. All Hull seemed to be rushing with us. Arrived at the front, near the Victoria Pier, the surface of the water was seen to be covered with burning pieces of the covering. I suppose the cellulose dope made it blaze with so much smoke, and the tide (it was almost dead low water) was carrying the burning material slowly up the river.

Right opposite was the rudder-end section, which I had seen detach itself from the airship and fall slowly and almost straight down. It was on the "Middle" sand, which lies some distance out in the river opposite the pier (and at that state of the tide might have only a foot or two of water over it). This part was *not* in flames, but nothing of the front portion, which exploded, remained above water except a few blazing and smoking pieces, which the water quickly extinguished.

You may guess what I think of such utterly misleading accounts as the following, which appeared the next evening in the London Press with absurd sketches:—

"It was like some huge elongated eggshell, cracked over a basin, and each end turned up for the yolk to fall out."

And another:—

"He said (the worthy "eye-witness" who gave the account to the Press) he was haunted all the way by the fear of the wrecked and blazing airship falling on to the people of Hull."

But the airship was never on fire over Hull, and the large piece of the rudder end, which had had no fire in it at all, broke up as the tide rose into fantastic shapes and presented the extraordinary appearance which pressmen arriving an hour later managed to record.

The first photograph undoubtedly showed smoke on the river, and was taken with a small camera from the shore, but at the moment I saw no interest in mere columns and patches of smoke, but rushed on to the pier to get on to the river for a close view.

A tug was just bringing in, I think, Capt. Wann, one of the survivors, and Neville (my son) and I just managed to jump from a slippery pier to its deck before it was away again. Owing to the extreme shallowness of the water on the sandbank, no tugs had been able to get close to the wreck, the rescue work being carried out by rowing boats. But by using the long boat hooks as sounders, we managed to find places where the water was deep enough for our tug to bring us into good positions for the camera. These views are the earliest taken from the Humber itself, and, looking towards Hull, have the advantage of making a record of the portion of the wreck against the outline of the city in the distance. Looking seaward, or towards the low Lincolnshire shore on the south, the historical value would have been much less. About an hour later our vessel returned to the pier and took off several other men with cameras, and they arrived on the scene when the wreck had broken up a great deal by the action of the tide, and had become perhaps a good deal more picturesque, although not appearing as it did when it first reached the water.

On reaching home I set to work enlarging the negatives to 12 x 10 for transmission to London by an early train the following morning. Some of the photographs have already appeared in leading newspapers without any acknowledgment of the photographs underneath, although the prints sent to an agency had the name, address and the word "copyright" carefully stamped on the back.

This is, of course, the chief return a professional photographer expects; the fees paid him by the Press are almost beneath contempt in many cases. I hope in the near future to initiate a discussion at our P.P.A. Council meeting on methods of preventing injustice of this sort.

TEACHING LANGUAGES BY PHOTOGRAPHS.—A Chicago contemporary tells of a plan worked out by a professor in the University of Oregon and used in the Spanish correspondence courses of that institution. Students had their greatest difficulty with pronunciation, until this teacher, recognising that the lips are used more than in speaking English, devised photographic aids. A series of 19 pictures are sent out with the lessons on pronunciation. These pictures show the position of the mouth in pronouncing all the difficult vowels, diphthongs, and triphthongs. The idea is that if the mouth is formed to the correct shape the issuing sound will be right. With the picture in front of him the student can practice the sound until he gets it

R.P.S. EXHIBITION LECTURES.

The following lantern lectures will be delivered during the forthcoming Annual Exhibition of the Royal Photographic Society, which will be open from Monday, September 19, to Saturday, October 29 :—

Tuesday, September 20.—Lantern Lecture : "London's Historic Mile," A. H. Blake, M.A.

Friday, September 23.—"Picturesque Cities of France," James Shaw, F.R.P.S.

Tuesday, September 27.—"Further Adventures among the Tree tops." Capt. C. W. R. Knight, M.C., F.R.P.S.

Friday, September 30.—"Wonderlands of the Western World," J. Dudley Johnston.

Tuesday, October 4.—"The Making of Portraits." C. P. Crowther, F.R.P.S.

Friday, October 7.—"Chartres Cathedral," E. W. Harvey Piper, Hon. A.R.I.B.A.

Tuesday, October 11.—The Twenty-fourth Annual Traill-Taylor Memorial Lecture : "Aerial Photography and Phototopography," Monsieur L. P. Clerc.

Friday, October 14.—"A Loon in London," W. L. F. Wastell, F.R.P.S.

Tuesday, October 18.—"Some Savoy Tributaries of the Rhone," E. W. Mellor, J.P., F.R.G.S., F.R.P.S.

Friday, October 21.—"Geological Rambles with a Camera," F. Martin-Duncan, F.R.M.S., F.Z.S., F.R.P.S.,

Friday, October 28.—"Durham Cathedral." H. W. Bennett, F.R.P.S.

FORTHCOMING EXHIBITIONS.

September 10 to October 8.—London Salon of Photography. Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

November 17 to 19.—Bowes Park and District Photographic Society. Particulars from the Hon. Sec., S. Smith, 68, Mannock Road, Wood Green, London, N.22.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

DEFEATING PIRATE PHOTOGRAPHERS.—During the staging of thrilling scenes for cinematographic purposes, many of the film producing firms in America have been greatly annoyed by amateur and Press photographers making exposures on arranged scenes, such as railway accidents, aeroplane stunts, etc. After spending £5,000 on staging and taking one scene, the officials of one cinematograph firm detected six pirate photographers at work upon it, and having many more thrilling scenes to arrange set to work to discover a method of preventing their open-air scenes being pictured by other photographers, particularly pirate cinema cameras After much thought and many experiments we are told that the reflection-mirror method was decided upon. When the next big scene was ready the producer detected several pirate cameras upon roofs and in windows, but this time (saye "Popular Mechanics") he was prepared for them. As many of his assistants as there were pirate camcras were on the scene with small hand mirrors The pirate camera men were not requested to leave, and no attention whatever was paid to them. When the scene was ready for taking, however, the men with the mirrors were ready. As the director called for his operator to begin filming, the men with the mirrors directed beams of reflected sunlight directly into the lenses of the pirate cameras. The reflected light in their lenses precluded the possibility of their taking the picture. Several of the pirate camera men went on photographing before they discovered the beam of reflected light in their lenses, but many observed the mirrors and beams of reflected light and simply picked up their cameras and tripods and marched away knowing that they were outwitted.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 22 to 27 :—

PHOTO-STENCILS.—No. 22.228. Photographic methods of producing stencils. M. J. D. Carter.

LENSES.—No. 22.231. Photographic objectives. C. C. Minor and H. A. de Vry.

CINEMATOGRAPHY.—N. 22.313. Cinematograph screens. W. Parker.

CONCEALMENT DEVICE.—No. 22,409. Device for concealing advertisements, photographs, etc. A. F. L. Smith and W. E. Tucker.

CINEMATOGRAPHY.—No. 22.527. Cinematograph screens. F. D. Sunderland.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR CINEMATOGRAPHY.—No. 166,344. (April 13, 1920.) The invention provides an apparatus with which two or three separate negatives for cinematography in colours may be taken by the additive method of colour-photography in such a manner that the pictures joining each other are placed one above the other on a continuous film, but so that the pictures, generally speaking, are placed on a shorter length than represented in the distances from one optical lens-centre to the lens-centre of the next lens in the lens batteries of the lenses employed, the direct light-cones forming the pictures being deflected. By reversing the light-action the same apparatus may be used to project the positive pictures in such a manner that the pictures are united into one picture of colours. To achieve this object two or three lenses are used and the two outside light-cones formed by such lenses are deflected by means of inserted wedge-shaped prisms.

In the drawings fig. 1 may be taken as the embodiment in a general way of this invention, and in which O^1, O^2, and O^3, are the three paired lenses which for taking pictures are generally

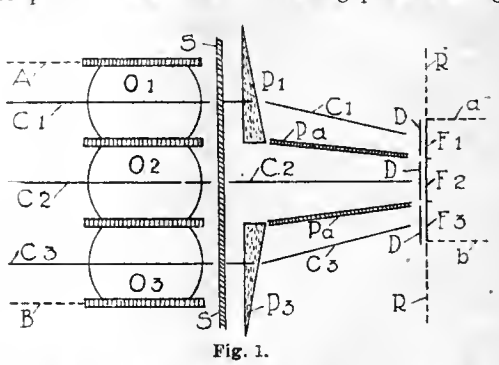

Fig. 1.

adjusted and then fixed together as a battery making one body and as a battery are movable for focussing purposes. This body of lenses project the pictures forming light-cones, C^1, C^2, and C^3, are the central light-rays in the respective projections, and such central rays passing through the combination arrive at their focussing planes F^1, F^2, and F^3, which in extent occupy the space *a—b*. This space is, in the drawing, given as half the length of A—B, the combined diameters of the lenses, but it is obvious that the space of the combined diameters of the lenses can be made to have other proportions as compared with the combined space of the focussing planes, *a—b*, and the deflection by the prisms has to be calculated to suit the respective case.

S, represents the revolving shutter, which could also be placed on the other side of the lenses. D, are the colour filters required by the additive method of colour photography. They could also be placed anywhere in the light-path if more convenient. P^1, and P^3, are the two wedge-shaped prisms of which the deflecting power is calculated so that the light-cone is deflected inwards

towards the central picture for just the amount required. Ps, stands for the partitions which are necessary to keep the different light-cones in their limited picture-plane and space. R, is the continuous film of the ordinary or desired picture width on which the picture series are impinged when taking the negatives.

For correcting or compensating purposes in the central light-path, C', a parallel, cylindrical, or lenticular plate or lens or block is inserted.

When reversing the light-action, the positives obtained from the negatives are placed in the same order in the apparatus, but if the apparatus remained as described above, the pictures would not unite into one colour-picture, since the central light rays

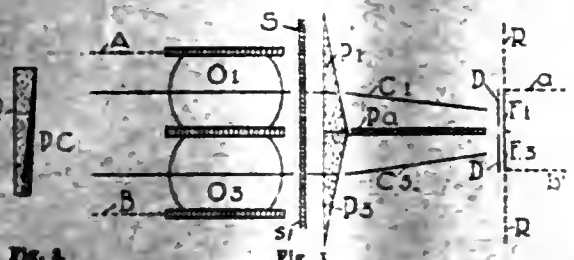

Fig. 3.

Fig. 3.

C', C', C', passing through the lenses are parallel. To arrive at that end several means of effecting this super-position may be used, *e.g.*, wedge-prisms with stronger deflecting power, or adjustment of the relative positions of the prisms, the lenses and the focussing planes by moving either the prisms or the lenses or both; or another prism may be placed in front of each of the outside lenses. Wedge-lenses, also called stereoscopic prism lenses could be used in place of the wedge-prisms, and would act similarly to the wedge-prisms and would be of special advantage in the apparatus when short distance projections are necessary.

An ordinary wedge-prism does not only deflect the light-cone, but if the wedge is of rather an obtuse formation, prismatic light-separation in the form of spectroscopic colour-fringes will be introduced and the more acute the wedge-prism used, the less will be seen of this light-separation, and the sharper will be the passed picture. Acute angled prisms are used in this apparatus, so the above named defect does not amount to anything destructive, but the defect can be corrected by compensation by cementing two smaller wedges of different glass together, as shown in fig. 3. PC, the compensation to P, the ordinary wedge-prism.

If a shutter of the generally known form (fig. 4) is used when exposures are made by means of a battery of lenses, such exposure is not alike in time through the different lenses and the correction is to provide the shutter with a different opening. The opening

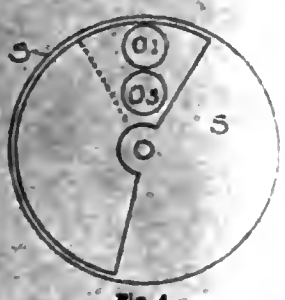

Fig. 4.

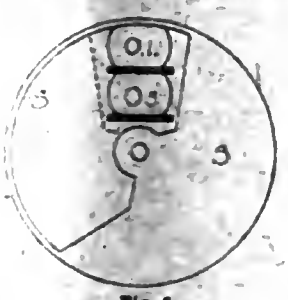

Fig. 5.

should be cut eccentrically, similar as shown in fig. 5; other eccentrically cut openings are naturally also possible. A good plan is to work a separate shutter for each lens or two shutters over three lenses, as the case may be.

While fig. 1 shows the embodiment of the apparatus, it is not necessary to employ the three light-cones; any two of the three light-paths can be used to form an apparatus taking a series of two pictures only. In that case one light-cone can be dispensed with altogether and as an instrument on that basis can be made, it has been thought advisable to give a separate illustration of a two light-paths apparatus in fig. 2, further description of which is, however, not necessary as the reference numbers and the letters employed therein, as well as in fig. 4, and fig. 5, are the same and refer to the corresponding parts as in fig. 1.—Otto Pfenninger, 44, Hitherfield Road, Streatham, London, and William Agate, 12, Liverpool Terrace, Worthing.

Aerial Photography.—No. 134,853 (August 24, 1915). The invention is an improvement on that of Eng. Pat. No. 134,851 ("B.J," March 25, 1921, p. 175). Instead of first taking a positive strip from the exposed film and cutting this strip into individual picture sections as previously, the exposed film itself is first cut into picture sections which are mutually superposed at their edges so as to eliminate repetition of similar portions of the picture appearing on adjoining sections. One of the

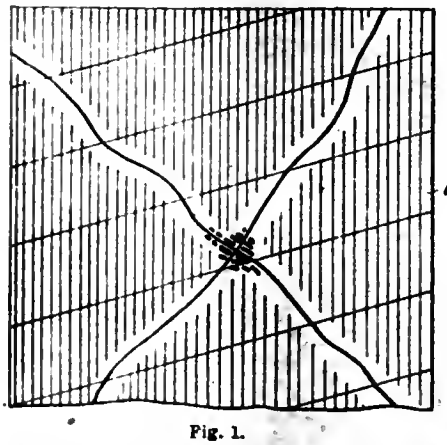

Fig. 1. Fig. 2.

overlapping edges of each section is then cut off, so that when the sections are again mutually arranged they will comprise a complete panoramic picture and present a flat surface. The complete negative thus produced is then preferably secured to a glass plate to facilitate production of positive copies.

Figs. 1 and 2 are respectively front elevation and transverse section illustrating a positive copy produced according to the present method.—Oskar Eduard Meester, 110-111, Leipzigerstrasse, Berlin, W.8.

Aerial Photography.—No. 134,854 (January 27, 1916). The invention is a modification of that in Eng. Pat. No. 134,851 ("B.J.," March 25, 1921, p. 176). A film band moved transversely to the direction of flight as previously is not used, but, instead, one which is moved in the direction of flight and is of such width that again dimensions of the resulting picture are, transversely to the direction of flight, a multiple of the dimensions in the direction of flight.

The apparatus employed for taking the exposures according to the present method will be substantially the same as that illustrated and described in the principal classification above cited.—Oskar Eduard Messter, 110-111, Leipzigerstrasse, Berlin, W.8.

The following complete specifications are open to public inspection, before acceptance:—

Colour Photography.—No. 168,035. Colour photography and cinematography. E. Wolff.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Wellington Speedy (Design).—No. 412,402. Photographic dry plates. Wellington and Ward, The Elms, Shenley Road, Boreham Wood, Elstree, Hertfordshire, manufacturers. February 18, 1921.

Dupli-Tized.—No. 416,805. Photographic film. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials. July 9, 1921.

Novabrom.—No. 416,635. Photographic printing paper and post-cards. Photo-Produits Gevaert (Société Anonyme), 23, Sapte Straat, Vieux-Dieux, Belgium, manufacturers of photographic materials. July 4, 1921.

Messrs. J. Lancaster & Son, 87, Parade, Birmingham, send us a prospectus of their condenser-enlarger, issued in five sizes and three patterns at approximately pre-war prices.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, SEPTEMBER 13.

Hackney Phot. Soc. "Kent, the Garden of England." A. Hester.
Manchester Amateur P.S. "Prints and Slides." H. B. Bradley.
Scottish C.W.S.C.C. (Glasgow). Enlarging and Combination Printing.

THURSDAY, SEPTEMBER 15.

Hammersmith Hampshire House P.S. "Home Portraiture." R. Chalmers.
Kinning Park Co.-op. Soc. Open Night.
North Middlesex P.S. "The A.B.C. of Enlarging." W. Mitchell Bond.

SATURDAY, SEPTEMBER 17.

Kinning Park Co-op. Soc. Outing to Bardowie Loch.
Scottish C.W.S.C.C. (Glasgow). Outing to Fereneze Braes.

CROYDON CAMERA CLUB.

Mr. F. C. Reynolds gave a highly entertaining chat on the tiny Principality of Monaco, with particular reference to the Casino and the various ways of losing, and occasionally winning money there, systematically and otherwise. He had been much struck with the church-like atmosphere prevailing, and so intense is the decorum that if cash or anything else is dropped, the correct thing is to call for an attendant, who worms under the table and restores it with expectant-tip expression. He, the lecturer, somewhat ambiguously said, had experienced this on one occasion.

At the end of his remarks an equipment for roulette was produced complete even to the rakes, and paper bags containing an equal number of haricot beans were distributed. This immediately converted the club rooms into a vegetarian gambling hell of the worst description. The "office boy" having inadvertently dropped some haricots called in vain for an attendant, and diving for their restoration found on return that Mr. Harpur had appropriated his stake. In attempting to eject him from the Casino the injured one succeeded in smashing his pipe. Mr. Witterick, plunging heavily on the lucky number 13, at one swoop amassed a highly nutritious, if somewhat indigestible, fortune. The other side of the picture was presented by Mr. Taylor who, early in the evening, lost his last haricot, and with ashen countenance left the table. A loud report followed as the *coup de grâce* was administered to an air-distended paper bag.

Commercial & Legal Intelligence.

NEW COMPANIES.

A. E. ASHBY, LTD.—This private company was registered on August 30, with a capital of £500, in £1 shares. Objects: To carry on the business of dealers in photographic supplies, etc. The first directors are: A. E. Ashby, 105, Woodhouse Street, Leeds; Alice Ashby, 105, Woodhouse Street, Leeds. Qualification: 1 share. Registered office: 105, Woodhouse Street, Leeds.

IMPROVED GLASS FOR DAYLIGHT LIGHTING.—Knowing the importance of greater conservation of daylight, research work of a leading American wire glass manufacturer has been directed towards the production of glass with high diffusing power. The American scientific Press states that it has been the aim of this manufacturer to provide a glass that would "handle" daylight to the best advantage, and that the glass is particularly suitable for roofs of workshops and studios. The result is in the form of a new wire glass, every square inch of which has 900 prisms that appear like tiny corrugations. Their shape and size have been scientifically determined to promote diffusion. The United States Government used over 100,000 square feet of this new glass for a single building, and the new glass is attracting much attention wherever it is being introduced.

News and Notes.

CANINE PHOTOGRAPHS.—The 5-guinea prize for the best dog-photograph (offered by the National Canine Defence League) has been equally divided between Miss Eleanor Warren, 105, Queen's Road, Loughborough, and Mr. A. Atkinson, 1, Wilton House, Alum Chine Road, Bournemouth, W. Fourteen others were highly commended.

THE STAFF OF MESSRS. LAFAYETTE, LTD., to the number of 46, had their annual outing at Westcliff, last week, when an enjoyable day was spent in games, swimming, motor-boat trips, and dancing. Votes of thanks to Miss White and Mr. D. M. Lundie and toasts to the success of Messrs. Lafayette brought a most successful excursion to an end.

LIFE LOST FOR A CAMERA.—Last week's newspapers told of a fatal accident at St. Malo, the victim being a Miss K. Emery, of Surbiton, Surrey. The lady was going by tram to St. Malo from Parame, when she dropped her camera, and jumped from the moving tram to recover it. Losing her balance, she slipped and fell under the following car. First aid was immediately forthcoming, but the victim died before reaching hospital.

HAMMERSMITH PHOTOGRAPHIC SOCIETY.—Our energetic friends at Hampshire House, Hog Lane, Hammersmith, have just issued the programme of lectures and papers for the session from September 8 to May 11. The fixtures cover a great diversity of subjects, and the programme includes a long list of well-known lecturers on photographic topics. Those in the west-end of London are well catered for by this society, the secretary of which is Mr. J. W. Carruthers, 18, Greenhill Road, Harrow.

THE AUTOTYPE CO., 74, New Oxford Street, London, W.C., have just issued their new trade price list for carbon and bromide enlargements, miniatures on ivory and ivorine, ceramic enamels, and other branches of service for professional photographers, including presentation oil portraits. Their department for printing and enlarging in bromide has recently been extended, and is now equipped in a most up-to-date manner, permitting of high-class work being turned out in the shortest time. The Autotype Company will be pleased to send a copy of this list to any professional photographer.

UNDER-STAMPED LETTERS.—An unusually large number of insufficiently stamped letters are now being sent through the post, especially to places abroad. A special notice has been sent out by the Postmaster-General reminding commercial establishments and others that the prepaid rate of postage on letters for all foreign countries (except the United States and Tangier) is 3d. for the first ounce and 1½d. for each succeeding ounce or fraction of an ounce. From the United Kingdom to British possessions generally, the United States, Tangier, and H.M. ships and troops on foreign stations, the letter rate is 2d. for the first ounce and 1½d. for each succeeding ounce or fraction of an ounce.

EDWARD FITZGERALD ON PORTRAITS.—Admirers of the Rubáiyát of Omar Khayyám" will no doubt be interested to know Fitzgerald's ideas on portraiture. In one of his letters (to W. H. Thompson) appears the following: "I am all for a little Flattery in Portraits; that is, so far as I think the Painter or Sculptor should try at something more agreeable than anything he sees sitting to him. When people look either bored, or smirking, he should give the best possible Aspect which the Features before him *might* wear, even if the Artist had not seen that Aspect. Especially when he works for Friends or Kinsfolk; for even the plainest face has looked handsome to them at some happy moment, and just such we like to have perpetuated." It is interesting to recall the fact (writes a correspondent) that in the well-known photographic portrait of Fitzgerald (taken at Ipswich) the subject is not by any means looking comfortable or pleasant.

CELLULOID FIRE DANGER.—The Home Secretary proposes to make regulations under the provisions of the Factory and Workshop Act, 1901, relating to dangerous and unhealthy industries, dealing with places in which celluloid, or any article wholly or partly made of celluloid, is manufactured, manipulated, or stored. The draft regulations, to which objections may be submitted before

September 20, provide, *inter alia*:—Stocks of celluloid shall be kept in a suitable place, outside the workrooms, plainly marked "celluloid store." Stocks exceeding one hundredweight shall only be kept in a chamber constructed of fire-resisting materials, in which no open light or fire shall be allowed, and which shall not be used for any purpose other than the storage of celluloid. The store shall not be situated so as to endanger the means of escape from the factory or workshop or from any part thereof in the event of a fire occurring in the store. The amount of celluloid in a workroom at any one time shall be kept as small as is practicable without unduly interfering with the work carried on. In the case of cinematograph film the amount in a workroom at any one time shall not exceed the supply immediately required for the work in hand. Cinematograph films, except while necessarily exposed for manufacture, shall be kept outside the workrooms in suitable receptacles provided with covers. Efficient steps shall be taken to prevent celluloid from coming into contact with open lights or fires, or, except to the extent that may be necessary for the processes of the industry, remaining near thereto. No open lights or fires shall be allowed in a room in which cinematograph film is manufactured or repaired. Adequate means for extinguishing fire, having regard to the amount of celluloid present in the room at any one time, shall be kept constantly provided for each workroom and storeroom. Adequate means of escape in case of fire shall be provided. Persons working in a "dark-room" shall be instructed as to the means of escape from such room.

Correspondence.

*** We do not undertake responsibility for the opinions expressed by our correspondents.*

THOSE LOCAL VIEWS! A SUGGESTION.

To the Editors.

Gentlemen,—To my mind, there is one section of the local view business that seems to be neglected, and as there is some depression in trade, doubtless there are many photographers doing a little local view-publishing as a side-line. I refer to interior subjects. Look in the stationers' shops, you will find the park, the town hall, the main streets, and the local public buildings will be shown taken from all aspects, but rarely will you see an interior of the smaller schools and churches. This fact was brought to mind by an experience of my own. I recently made two views of a small Sunday school, an outside view and the interior, and although there are scores of postcards of our town, so far as I can gather these are the only two views that have ever been taken of this place. I first showed them to one of the officials of the place; he sold a gross of postcards on the spot the same day, and they are still going strong. After this experience I made up my mind not to neglect any subject, because however small it may appear, there are usually sufficient people interested in it to make the job worth while. Look at the public school. You may see a picture of the scholars, of different classes, but rarely a view of the old schoolroom itself; and those of us whose school-days are now in the long past would rather like a picture of the old room with the schoolmaster's desk, even if it brought back painful memories. Having got the negatives, there is no need to send them away to be printed unless one so wishes; they may be done at home with the strip printer, and there are few of us who do not use one nowadays. You can do a good number on a quiet half-day, and there is no difficulty about the work. The views may be taken at dinner time when the scholars are away, or on Saturday when there is a holiday.

Do a few samples, both black and white and sepia, and take them to the stationers' shops, not forgetting the one nearest to the place taken, as then they are sure to be seen by the scholars. If you feel you have got something a bit exclusive, make a small enlargement; it will draw attention to the smaller pictures, and the shop-keeper will only be too pleased to exhibit it for a time as an attraction to his window. To conclude, make a good job of it, put your name on each card, and I think you will find this branch of photography quite worth while, whether in postcards or larger sizes.—Yours faithfully, H. CLEWES.

80, Cherrytree Lane, Stockport.
August 26.

SYSTEMATIC BROMIDE PRINTING.

To the Editors.

Gentlemen,—The articles by Dr. Glover on bromide printing are extremely interesting and valuable, but I am afraid the average bromide printer will not pay much attention to them; he prefers his own rule of thumb method. I must confess he generally gets very good results, but he would probably do better if he would adopt some system of timing development, as well as exposure. In conversation with Mr. Watkins, a good many years ago, he said that he found that his factorial system was excellent for bromide printing, but I did not try it for a long time after. I did not find the complete factorial system answer for regular professional work, but developing for a stated time proved of great service, especially for prints to be toned. We found that as a general rule whatever the exposure might be no print would tone well, or even become a good black print, that was developed for less than three minutes. There were exceptions, however. I had a few extremely hard negatives of pictures to be printed, 12 x 10 size, and I failed to get satisfactory prints with metol or amidol. I tried exposures that ran into minutes, but could not get a decent print. At last I tried amidol made decidedly alkaline with sodium carbonate, with greatly reduced exposure; after a good many experiments I got quite good prints by giving an exposure of thirty seconds and a development of about sixty seconds. Of course, this meant developing one print at a time, but at any rate I got the prints done, and quite good ones too. But I should not recommend such a method for regular work. It was to suit an exceptional case. Out of curiosity I toned one of the prints and was surprised that it came quite a good colour. I expected it would be very yellow. But amidol gives a colder colour than metol and hydroquinone, and requires a shorter exposure, and this, I think, accounts for the cooler colour. If Dr. Glover would follow up the experiments he records in Table II. by toning the prints he would add to the debt we owe him already. I have always argued that the colour of a toned print depends upon exposure; a short exposure and prolonged development giving a cool colour, and long exposure and short development a warmer colour. But I would like to have this confirmed by a trained investigator, for the professional photographer has neither the time nor the knowledge to make exact scientific experiments. But I am quite sure from my own experience that it is a good plan to adopt a standard period for the total time of development; as I have already said, three minutes proved to be the minimum.

When a large number of prints have to be developed it is difficult to note the time of appearance and the total time of development, but this is quite simple when making the trial print, and to adjust the exposure to give a development time of three minutes. I prefer, if possible, to modify the light to suit the negative, so that an exposure of not less than five seconds may be given; if a printing box is used sheets of waxed paper may be added for a thin negative and taken out for a dense one, and if an ordinary printing frame is used the distance from the light may be varied until five seconds becomes the correct exposure. I prefer this, as it is difficult to give exact exposures of less than five seconds, even when using a special dark room clock. It is useless to expect a series of bromide prints to be uniform, either in depth or colour, unless identical exposure and development have been given. Some assistants will try to save the trouble of using a clock and count the time of the exposures. If I find this going on I stop it at once, as no two people count at the same speed, and probably no one counts at the same speed for every exposure, so that it becomes almost impossible to get a dozen prints all alike to complete an order. Assistants vary so much in this matter, especially when young beginners. For instance, one boy would be given a dozen negatives to make a print from each, and he would do what

I could not do myself; he would get a good print from each negative straight away, almost without a failure. But if he were told to get a dozen good prints from one negative he could not do it. No two would be alike. Another boy would be quite unable to get a decent print "on his own" from any of a number of negatives, but show him the exact exposure and depth to develop for a certain negative, and he would make any number of prints all alike. A system such as Dr. Glover recommends would make good printers of both those boys if they would follow it carefully.

But I can see difficulties in following out this system when a large number of prints have to be made from one negative, because they cannot be developed one at a time; probably a dozen prints will he in a developer at one time in different stages of development. My own method is to make my trials until I get a correct print when viewed by daylight, if possible with five seconds exposure and three minutes development, perhaps sometimes three-and-half or even four minutes. Then expose as many as may be required and proceed to develop, but, of course, in developer of the same constitution as the trial. One print is slipped face up into the solution and the time noted, a second print is then slipped under the first and brought to the top, and then the first is brought to the top and a third slipped under the second, and so on until about six prints are in the solution. The prints are kept face up and constantly moved, bringing the bottom print to the top. The first print will be easily detected as it is the darkest, and when I am printing I always put not only the number of the negative, but also the consecutive number of print exposed; they are kept face down until developed and slipped into the developer in order, so that the first print to go in bears the highest number. By this means it is always possible to know which print has been in the longest. At the end of three minutes the first print should be ready to take out. A fresh exposed paper is then slipped under the bottom print and brought up to the top as before. All the prints are moved in the same way until the fresh print is again at the bottom, and another fresh print slipped under at the bottom. By this means the prints are kept in consecutive order, and by bringing the bottom print to the top one sees the prints in order, graduated from the least developed to the one that is almost finished. Of course, by this method the time of development of the second and subsequent prints cannot be ascertained, but the eye should be able to judge by appearance after having had the first print as a guide. I do not see how the time of development of each print can be counted when a number are developed at once. I think the advantage of this method is that the eye is led by degrees from the least developed, and one's judgment is not upset by seeing perhaps a print half developed, and the next to it may be one just put in and the next almost completed. If the fresh print is put in the developer at the top, one sees the prints in the wrong order from the darkest to the lightest, and then the darkest again, so that the eyes, instead of being led from the lightest to the darkest, see the darkest print next after the lightest, and the eyes cannot estimate the proper depth of the darkest print, and one is apt to take it out of the developer too soon.

But some systematic method is necessary if prints are to be uniform, especially for toning.

I am not sure that amidol is the best developer for large numbers, because its life is so short, and it seems to lose its developing power so soon. It is true that "Serteka," glycollic acid and other preservatives prolong the period during which it remains active, and prints developed with amidol seem to tone to a more uniform colour than when other developers are used, even when the time of exposure and development have been varied. When large numbers are to be developed I should prefer D.50, for it seems to retain its power longer than any other developer I have ever used.

Dr. Glover's experiments, I have no doubt, will prove of great value to the careful worker, but the professional works under such totally different conditions from the scientific investigator that the latter methods often have to be modified considerably before a practical working system is evolved. And there is always the difficulty of persuading one's assistants to give the new ideas a fair trial. And they have to be persuaded and not coerced, as many show an aversion when new methods are suggested.

Some experiments on the lines indicated by Dr. Glover tend to confirm his statements. It was found that when using D.50 as a developer, with the same negative on different brands of paper, a multiplying factor of seven gave correct development. The image appeared in thirty seconds and development was completed in three and a half minutes. The exposure was five seconds.

It was found possible to time each print of a batch. The first was put into the developer and the time noted; at the end of thirty seconds a second was put in, and so on at intervals of thirty seconds. By this means it is possible to take each print out at the end of three and a half minutes. But an expert printer would be able to dispense with this method, although it would very greatly help a beginner. It will be interesting to hear the views of other workers. Dr. Glover's articles will prove, I believe, of great value. —Yours faithfully,

Birmingham. HAROLD BAKER.
September 3.

To the Editors.

Gentlemen,—I always read Dr. Glover's papers on the factorial development of bromide paper with the greatest interest, and I feel that all workers in bromide whose aim is to get the best out of their medium, owe him a debt of gratitude for his work in this direction.

There are, however, two difficulties in his method on which I should be glad to have an opinion. Dr. Glover states, in your issue of September 2, that "both the trial strip and the final print must of necessity be developed to the same factor." While admitting this, I find difficulties in securing its accomplishment. The range of test exposures I usually take is 5, 7, 10, 15, 25, and 40 seconds, and the time of appearance of each section varies from its neighbour, so that one has a latitude of several hundreds per cent. in estimating the time of development.

Further, assuming the above difficulty to be surmounted, if the time of appearance of the test exposure strip—and, in consequence, its total time of development—is to be the same as that of the final print, it is essential that the test strip should be made in the shadows. Such a test, however, is of little value, as it gives no indication of the exposure necessary to give gradation in the high lights.

My own practice is as follows—whether it would meet with Dr. Glover's approval I cannot say:—"Using the Kodak amidol formula (on either Kodak or Ilford paper), I take the factor which Dr. Glover originally recommended, namely, 15. I know from experience that this factor, under my normal working conditions, requires a development time of about four minutes. I make a test exposure in the highest light in the print, and develop for this time, select that exposure which is just sufficient to give the high-light detail, and develop the final print to a factor of 15.

The use of the factor is an absolute safeguard of the quality of the print, and I do not often find any serious discrepancy between the depth of the print and that of the correctly exposed portion of the trial strip.—Yours truly, J. AINGER HALL.

28, Bishop's Mansions, London, S.W.6.
September 5.

THE KODAK MANUFACTURING POLICY.

To the Editors.

Gentlemen,—I have read with interest, in the current issue of the "B.J.," Mr. Herbert Lambert's comments under the above heading.

I confess that I permitted myself a smile when I perused the "Announcement" referred to, because I, myself, like Mr. Lambert, have gone back to plates after making what I considered a very fair trial of the much-boomed portrait film. Mr. Lambert suggests that a question of "profits," perhaps, was the main factor which induced Messrs. Kodak to forsake plate manufacture. I should scarcely endorse this fully. What I imagine is that Messrs. Kodak have developed a touch of what our trans-Atlantic friends term "cold feet," through keen but none the less effective competition on the part of certain of our own native British plate-makers. One firm, at any rate, have recently instituted a competition which is bound

to produce some fine examples of professional portraiture, and, I think, Messrs. Kodak's kind intention is, if possible, to create an unreasoned bias beforehand against anything which is designedly shown as due to a good old dry plate.

But this is only conjecture. I feel, at any rate, on securer ground, in discussing my experience of portrait film itself. As film, it was lovely to work with, but in my own case any good qualities were outweighed by the following main disadvantages:—

Firstly, the need for full exposure. With shorter days rapidly coming in, I do not envy the operator who has to work with portrait film exclusively for daylight exposures. Perhaps, however, Messrs. Kodak are projecting another startler, this time in the way of a new type of illuminant which will put our old friend, King Sol, in the shade.

Secondly, came the facility of the film for accumulating scratch marks on the back. These marks, I found, were artful enough to remain practically invisible until some stray dust had made for itself a comfortable home inside the scratches. A remarkable penchant for finger-marks was also to be noted.

Thirdly, I needed to take almost extravagant precautions in wintertime to ensure that a film negative was thoroughly dry before proceeding to enlarge from it to any extent. Possibly, however, the new Kodak projection printer overcomes this objection, and might even permit the printing of film wet from the wash-water in case of urgency. It may also inhibit any scratch markings, however pronounced, but, even so, some simple and unprogressive souls might consider it to be on the dear side, even though resolutely sacrificed at a mere trifle of £120. But this is only by the way.

But I think that what I have written will do for now, as serving to demonstrate my opinion that plate-manufacturers generally need not think of closing down yet awhile; in fact. I have noted, with some pleasure, that two of your regular advertisers are by no means despondent, judging by their own "announcements" in the "B.J." on the matter. While in this connection I have also observed that Messrs. Kodak have prudently left themselves a way of retreat in case of necessity, by saying in a concluding paragraph of their "Announcement" that they will unhesitatingly send portrait film to the scrap-heap when a better medium is discovered. It would provide a good blaze, anyway, when a lighted match was applied! So would studio premises in which a few thousand film negatives had accumulated.—I am,

Yours faithfully,

J. Mallinson

The Studio, Shrewsbury, September 5.

To the Editors.

Gentlemen,—I was very much interested to note in the columns of the last issue of the "B.J." the discussion provoked by the recent announcement of the Kodak Co. regarding the discontinuance of their glass plate manufacture. The writer, however, devoted but little attention to the relative merits of film versus glass, dismissing this all-important phase of the question with the statement that he personally had tried film and found them no advantage over the glass plates. The rest of his letter consisted of conjectural statements founded upon his private opinion which he took as axiomatic. The purpose of this conjecture was to satisfy himself, and possibly his readers, as to the motive behind the Kodak Co.'s action.

It does not seem to me that we photographers need be very interested in the motive lying behind a manufacturer's decision to manufacture or not to manufacture any particular article, when there are many other manufacturers still making the article which the one discontinues. In short, if we wish to use plates, we can still use plates; our hand is no way forced.

Yet I do think that all of us are interested in this growing favour for flat films, and I think discussion on the relative merits of films and plates can be very useful. This house being the very first user of films, I would like to have my say on the other side of the question. From the commencement I noticed that the quality of the film was excellent, in my opinion, better than any plate, and that the non-halation it possessed over plates could be used to good account. Therefore, to me the answer to the question is in the product itself. In my opinion the quality is better, and it enables me to do better work; that is all I ask.—Yours faithfully,

H. Walter Barnett and Co., Ltd.,
O. Hardee, Managing Director.

12, Knightsbridge, Hyde Park Corner, London, S.W.
September 6

To the Editors.

Gentlemen.—I regret to note that Messrs. Kodak, Ltd., are discontinuing the making of glass plates. I have used their plates for some time and found them to suit my work in every way.

I have given the portrait films a good trial, having used about a gross of them, but I do not like them. There are two strong objections, in my opinion, i.e., they are a nuisance to retouch, owing to having to be held down all the time, and in damp weather the gelatine backs are so soft they pick up all kinds of dirt, and very easily get scratched. It is impossible to clean the backs like a glass plate. Also, I find they do not "scrape" so well as a plate.

They are a nuisance in the enlarging lantern, and for "sketch" printing they have to be fastened in the masking card with gum-paper. Their great advantage is freedom from halation, but I have never had much trouble with that in the studio, as careful lighting obviates it.

I, like Mr. Lambert, must find another plate to suit.

Yours faithfully,

Andrew C. Glover.

St. Ives, Cornwall, September 3.

INTERESTING THE SITTER.

To the Editors.

Gentlemen,—In the "Ex-Cathedra" notes appearing in your pages dated August 5, mention is made of the old saying that Sir Joshua Reynolds wished he could dine with a man before making a portrait of him. The writer of the paragraph (page 457), referring to the story, says very wisely "whether this be true or not," having apparently no reliable evidence as to the authenticity of the statement. Sir Joshua's "desire to dine," however, has been made such good use of by writers on portraiture that most students are in the habit of taking it as gospel, having no reason to doubt it, and no wish to spoil a good story—if they could.

We have, I believe, the famous essayist, W. Hazlitt, to thank for some very good—if not the best—details of Reynolds's methods of working, but the dining story of Hazlitt's differs slightly from the modern version. Hazlitt, as a lad, may or may not have known Reynolds personally—the artist dying when the essayist was but fourteen years of age—but it is certain he knew many of the artist's sitters, and probably had no difficulty in getting from them his methods of working.

What the essayist says is this: "Sir Joshua formed the circle of his private friends from the *élite* of his sitters; and Vandyke was, it appears, on the same footing with his. When any of these noble or distinguished persons were sitting to him, he used to ask them to dinner, and afterwards it was their custom to return to the picture again, so that it is said that many of his finest portraits were done in this manner." And further: "During the first sitting, Sir Joshua did little but chat with the new candidate for the fame of portraiture, try an attitude, or remark an expression. His object was to gain time, by not being in haste to commit himself, until he was master of the subject before him." We are also told by Hazlitt that none but friends and acquaintances of the sitter were allowed in the studio during the progress of a portrait, that cake and wine were always handed round, and that "he (Reynolds), as it were, by this act of hospitality, assumed a new character, and acquired a double claim to confidence and respect."

As far as I can discover, this is the origin of, and all the authority we have for, the oft-quoted statement concerning the wish of Reynolds. At any rate, except for the dining and the wine and cake, it will be noted that all really good photographers of to-day work something after the manner of Reynolds as regards interesting their sitters.—Yours, faithfully,

Godfrey Wilson.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

X. G.—We have not heard anything further in regard to the process. If you were to address a letter to Mr. John A. Tennant, editor of the "Photo-Miniature," 103, Park Avenue, New York, he would pass on your inquiry to the people who are interesting themselves in the process.

A. W.—(1) Of the two formulæ for the mercuric-iodide intensifier we prefer the one made up with sulphite for moderate degrees of intensification. (2) There is no advantage in using an acid fixing bath when it is intended to reduce or intensify negatives. (3) Yes, if the negatives suffer from under-exposure, and probably are, therefore, somewhat hard in contrast, the mercuric-iodide or the uranium intensifier is the most suitable.

F. P.—Your plan for a studio should work out all right, but as the width is so little (get 12 ft., if possible), it will be better to have a longer run of glass than 10 ft. Four feet of solid wall and roof at either end is quite enough. If you want to take a large group, or even a single full length, you will have to take the figures close up to the end wall, and then the longer light will give a more even lighting on the shadow side. You will also find it useful for back or Rembrandt work, as the studio will be too narrow to work across. Be sure to have enough *thin* white curtains to cover the glass entirely when the sun is on it.

H. H.—We are afraid we do not know enough about the matrices of the Roneotype and Neo-Cyclostyle to be able to say whether these machines can be utilised for your purpose. For such a considerable number of copies we should think the cheapest plan would be to have a zinco made and get a printer to run off this number of impressions from it. You could, no doubt, prepare a litho transfer and lay it down on your stone, but litho work requires a fair amount of practice. About the best book containing instruction in it is "Photo-Mechanical Processes," by W. T. Wilkinson, published by Messrs. Hamptons, Ltd., 12, Cursitor Street, London, E.C.4, price 4s.

W. A.—(1) We have never heard of *s*/11, but imagine that it is an equivalent of *f*/11. (2) We have not experience ourselves, but it is evident the author finds that he can remove the effect of exposure. (3) Very inconvenient in our opinion since it has to be used on a tripod, and then it is very awkward to see the image on the ground glass. Moreover, a wide-angle lens has often to be used in interiors and that cannot be fitted to the reflex type of camera. (4) Perspective has nothing to do with the size of the image of an object, but only with the distance of the object from the camera. The focal length of the lens then determines the size (scale) of the image.

W. H. W.—The process of Fox Talbot's, of 1852-8, is really the modern photogravure. If you apply to Mr. John A. Tennant, the "Photo-Miniature," 103, Park Avenue, New York, you can get a text-book on this process, although a systematic course of instruction is necessary in order to obtain proficiency in working it. For making prints in quantity without elaborate mechanical plant about the only process which is within the competency of anyone with the average photographic experience is collotype (again, text-book from "Photo-Miniature"), but it requires a lot of practice, and we should say that when time and labour are taken into consideration there is nothing cheaper than the multiplication of prints on bromide or D.O.P. paper.

J. N.—We are not surprised that you get a milky kind of deposit when cleaning negatives with fluoric acid, since the acid etches the glass, and, in some cases, produces a matt surface. If you can let negatives soak over night (in an earthenware vessel) in a fairly strong solution of nitric acid, the films will become so rotten that they can easily be scrubbed off the next day. Buyers of old negatives usually clear off the films by dipping the plates for a few seconds in a very hot solution of caustic soda, but this is liable—according to the quality of the glass—to cause a slight opalescence on the surface, which cannot be removed. Nor is there any means of getting rid of the matt markings produced by your fluoric acid.

J. H.—The formula recommended by the makers of D.50 is as follows:—

	A.	
D.50 concentrated solution	.....	250 minims.
Water to make	.....	10 ozs.
	B.	
Sodium sulphite, cryst.	.....	400 grs.
Sodium carbonate, cryst.	.....	250 ,,
Potassium bromide	.....	5 ,,
Water to make	.....	10 ozs.

For use take equal parts.

J. LADE.—(1) On the whole, nothing very much better, although it blunts the trimming knife somewhat quickly. Some people prefer to use cork lino. (2) A focussing mount is one which contains the lens in an inner tube, which can be moved to and fro in the outer tube, the adjusting lever indicating the distances of objects from the camera, which are in correct focus when the lens is in the respective positions. The mount is, in fact, a substitute for the focussing scale, but, of course, the lens requires to be fixed on the camera so that—at a given extension—objects in the extreme distance are in focus. For this reason a mount of this type is usually employed only with cameras having one fixed extension, for example, the folding focal-plane. (3) The strong dextrine mountant sold under various names ought to be sufficiently adhesive. Gelatine, applied hot, ought to answer, but is far less convenient. (4) Messrs. Fairbrother and Bowen, 9, Farringdon Avenue, London, E.4.

W. T. SMITH.—(1) The following method is, perhaps, the easiest for you. Though it is not quite accurate the error is very small, probably not more than one-eighth of an inch with a lens of average size and type. Focus on a flat object (say a foot rule) so that the image on the focussing screen is the same size, that is to say, 4 inches on the rule measures 4 inches on the focussing screen. Then, without moving the camera, measure the distance from the object to the ground glass and divide it by 4. The result is the focal length of the lens. (2) The lens you name is quite a good lens of the old type, but 8 inches focal length is rather short for covering a half-plate to the corners. We should prefer to have a lens of 9 inches or even 10 inches if it is not an anastigmat. When stopped down, no doubt, the lens will cover quite satisfactorily. (3) The Whitworth thread is that known as quarter-inch Whitworth standard. If you go to any maker of tools you can get a screw, say, in the form of a bolt, of this size and type.

Contents.

SUMMARY.

The exhibition of the London Salon of Photography opened on Monday last at the Galleries of the Royal Society of Painters in Water Colours, 5a, Pall Mall East. Mr. F. C. Tilney, in the first portion of his review, deals in detail with the various types of portraiture on the walls, and particularly with the character and pictorial portrait studies, which, as in former years, outnumber what may be termed the legitimate professional studio portraits. (P. 547.)

The exhibition of the Royal Photographic Society opens on Monday next at 35, Russell Square. (P. 545.)

The twenty-fourth Traill Taylor Memorial lecture will be delivered at the Royal Photographic Society on Tuesday, October 11, by M. L. P. Clerc, on aerial photography and photo-topography. (P. 545.)

In his "Paris Notes," M. L. P. Clerc reports some new photographic appliances now being shown in Paris, and describes the Dufay process of colour photography on paper, as disclosed in a patent specification just published. (P. 549.)

The relative merits of plates and film were debated in the customary manner at the Croydon Camera Club, and are the subject of further letters from correspondents. (Pp. 555 and 557.)

In an article on the speed of a lens, the principle of the rule according to which the focal length is divided by the diameter of the stop in order to obtain the F number is explained. (P. 550.)

The actual diameter of the stop is not the aperture which is effective if the stop is behind a converging lens, as it is in most doublet and compound objectives. (P. 551.)

In certain circumstances the effective aperture of the stop is liable to variation from other causes, but this variation seldom occurs, and is always of relatively small amount. (P. 551.)

The older systems of marking lens apertures sometimes give rise to confusion with present-day F numbers. Lenses of Dallmeyer, Goerz, Voigtländer, and Zeiss were formerly marked with special numbers. The F numbers equivalent to the markings adopted on these now obsolete systems are given in the article. (P. 553.)

Also, the F number varies with the scale of reproduction of a relatively near subject. The rule for ascertaining the exposure compared with that when photographing same size will be understood from the last section of the article. (P. 553.)

In circumstances when a studio conforming to one or other of the recognised types cannot be secured, more than ordinary attention is required as regards its dimensions and aspect if satisfactory portraiture is to be done in it. We refer to some of these questions, and to the means which can be taken to improve the working conditions in a relatively unsuitable place, in a leading article on page 546.

Dr. J. M. Eder strongly repudiates the recent criticism by Mr. E. J. Wall of his account of the origins of flashlight photography. (P. 559.)

Definite quotations of price is a practice which will often save subsequent unpleasantness in undertaking commissions away from the studio. (P. 546.)

EX CATHEDRA.

The Traill-Taylor Lecture.

For the first time during the twenty-four years since the Traill-Taylor memorial lectureship was established, the lecture will be delivered by a Frenchman. On the forthcoming occasion of the twenty-fourth lecture, on October 11, the lecturer is to be M. L. P. Clere, who for many years has occupied a leading place in France as an authority on photographic technique and on the scientific principles of photography. During the war M. Clere was commander of an aerial photographic section and instructor in aerial photography at the headquarters where training was carried out for this branch of the military service. It is, therefore, appropriate that he should take as his subject "Aerial Photography and Photo-Topography," subjects in which he not only took a practical interest, but to which he made valuable contributions by way of the establishment of accurate methods of procedure. M. Clere is the author of two treatises on aerial photographic methods, issued uniformly with his earlier works on photo-mechanical reproduction in monochrome and in colour. As he speaks English with considerable fluency there is no doubt that his discourse on October 11 will be one which should attract a large audience.

* * *

Salon and Royal.

The exhibition of the London Salon of Photography, which opened on Saturday last at the Galleries of the Royal Society of Painters in Water Colours, 5a, Pall Mall East, has proved once again a remarkably fine collection of current work in pictorial photography. As will be seen from the very understanding and detailed review by Mr. Tilney, which appears on another page, there are remarkably few exhibits on the walls which do not call for careful consideration. The fact that the "Times" of Friday last reproduced on a large scale two of the works from the Salon (one of them, Mr. Thomas's fine portrait of the Lord Chief Justice) is a sign of the place which photography has made for itself among the fine arts in the estimation of the public. The Salon remains open until October 8. Monday next, September 19, will see the opening of the exhibition of the Royal Photographic Society at 35, Russell Square. Apart from the pictorial section, several exhibits of exceptional interest will be included. One of these is a specimen of the remarkable process of M. Louis Lumière, in which the sensation of solidity and relief in a portrait is produced by the arrangement of several positive transparencies, one behind the other, in front of a source of diffused light. The mathematical principle of this process was set forth some months ago by M. Lumière in a paper which appeared in our pages. Another exhibit is the collection of apparatus and specimens, formerly belonging to Fox Talbot, which has recently passed into the keeping of the Royal Photographic Society. The

exhibition at Russell Square remains open until October 29. Lectures are delivered every Tuesday and Friday evening during the period of the exhibition; those during next week are by Mr. A. H. Blake and Mr. James Shaw, of Manchester.

* * *

Quote the Price. Much unpleasantness has been caused by omitting to give a fairly close estimate of the cost of work which is not quoted in the price-list, and good customers lost in consequence of over-charge, as they have considered it. This refers not only to difficult copies and enlargements, but also to some classes of outdoor work. We have in mind a case which recently came under our notice wherein a photographer in North London was instructed to go to St. Albans and photograph some houses which his customer was trying to sell. Upon receiving the bill the customer was very wrath at the charge made, which was about three times as much as had been previously charged for a similar job done within half-a-mile from the studio. Although the charge was quite a fair one considering the time taken and the expense of the journey, a considerable reduction had to be made to avoid losing future orders. The same trouble has often arisen over other classes of work, so that it is always a wise precaution to agree upon a price which is then quoted in writing before starting upon the job.

UNORTHODOX STUDIOS.

THERE is a certain number of types of portrait studios which are generally allowed to be eminently suitable for the purpose for which they are constructed. Among these are the ordinary span roof, the single slant and the high side light, which is also known as "Robinson's Studio of the Future." In these days, however, it is not easy for the photographer who is starting in business, or who has perforce to seek fresh quarters, to find premises of these orthodox types, so that it becomes necessary to consider how far less suitable rooms can be effectively used for portraiture.

In the infancy of photography we find that the Daguerreotype operators worked either in the open air or in any well-lighted room which was available, but it was not long before it was found necessary to build special rooms, mainly covered with glass to reduce the length of exposure. When wet collodion came to the fore, although it was much more rapid, the glass room was still found to be necessary, and it has survived to the present day, although it is now by no means indispensable. With the rapid plates now available extremely short exposures may be given in any well-lighted room, and if we except full-length figures, the lighting should not be inferior to that obtainable in a specially-constructed studio. As a general rule, the principal light should fall upon the head of a seated figure at an angle of forty-five degrees. This condition can be secured with a window having the top about eight feet from the floor, this height allowing the sitter to be placed at a convenient distance from the glass. The length and breadth of the room and the position of the window or windows are also important factors, for if there be only a single window in the centre of the wall the working distance will be reduced and a short-focus lens with its attendant disadvantages will be necessary. The breadth should be sufficient to allow of Rembrandt, or what our American cousins call "line," lighting to be practised. Usually, a room with two windows on one side, instead of a single window, is to be preferred; the second window will serve to give a general illumination and prevent heavy shadows. The windows need not come within three or even four feet from the floor, but should be as wide as possible, as it is difficult to obtain soft effects when using a narrow source of light. The orientation of the room has an important bearing upon its suitability for portraiture, inasmuch as it will not be possible to move the sitter to obtain suitable lighting as in an ordinary studio. If available, a northern aspect is the best, for the reasons that it gives a steady light during the greater part of the day and that little diffusion will be needed. On the other hand, a southern or western aspect is a bad one for a room studio, because much light will be lost by having to use strong diffusers which militate against crisp soft lighting.

Another type of room is often found at the top of large city buildings. In this, the illumination is furnished by a skylight, either flat or in the form of a cone. Such rooms usually make good studios, their principal fault being that owing to the distance between sitter and light, the exposures have a tendency to be rather longer than with a side light. This is not, however, serious, as it will rarely cause a greater difference than that between plates working at 350 and 500 H. and D. In top-light studios a large mirror can generally be used with good effect as a side light, while large white reflectors of the ordinary type give a softer light from the same direction. It may be necessary to point out that the efficacy of a reflector depends not only upon the reflective value of its surface but upon the volume of light which reaches it and the angle at which it impinges. In the ordinary studio there is usually a sufficiency of light falling upon the reflector, often too much, but with a single small source of light one has to be careful to use it properly. Full-length figures are difficult to render satisfactorily in a studio with a low side-light, and fortunately they are little in demand. If electric current be available a half-watt or mercury-vapour lamp placed near the ceiling will give the necessary top light. Failing this, a row of incandescent gas burners, used as a "batten light," will be a handy substitute. With a top-lighted studio it is easy to make full lengths, if the figure be judiciously placed in relation to the skylight, that is to say, not directly beneath it, or an outdoor effect will be produced.

When equipping studios of the types we have mentioned care should be taken to eliminate every unnecessary article, as nearly all variations of lighting must be obtained by moving the sitter or the camera. For this reason the floor should be kept as clear as possible, and the camera and stand should be no larger than is necessary. It is now rare in most middle-class studios for larger pictures than whole plates to be made from direct negatives, and it is foolish to block up valuable space by installing a 12 x 10 or 15 x 12 outfit when the smaller and less-costly apparatus would answer the purpose as well, if not better.

The backgrounds should be fixed upon light frames fitted with castors, and they should be no larger than is necessary. One frame 8 x 6 feet will carry a white and a very dark grey for full lengths, while smaller ones, say 6 feet by 4, will be large enough for sitting figures and heads. These smaller grounds should have a little graduation or a foliage suggestion to give relief to the figure. Diffusers may be made of cheese cloth for ordinary light, and nainsook or even calico for bright sunlight. To meet the latter contingency a white blind should be provided to cover the entire window. There is a temptation to use tracing cloth for this purpose, but this material does not prevent glare so well as an undressed fabric like nainsook.

THE LONDON SALON OF PHOTOGRAPHY.

SLOWLY, but without doubt surely, a change is taking place. It is not a change that makes an exhibition of one year different very appreciably from another; but it tells by the inevitable dropping out of the commonplace and uninspired and the gradual increase of interest in subject and treatment of pictorial and portrait photography. Of course, there is always the selecting committee filter to reckon with. This body may strain out all the bad more effectually one year than another. To receive a proper impression of the current work one should see it all—in Olympia, perhaps, for several consecutive years. Fortunately, that is not possible, but to see the bad as well as the good is the only way to determine how things are developing. Judging from the present show at the R.W.S. Galleries, the good things which have got through are healthily plentiful. Technically, the work is everywhere at a high level, and "straight" work is gaining ground. In the portraits a genuine art motive is usually evident, and the professional is claiming a large share of the space in what was once practically an amateur collection.

Mr. Crowther's Surprises.

The surprise of the season is the work of Mr. C. Pollard Crowther, in the shape of two of the most captivating portraits in the show. They are entirely different in inception and manner, and between such antitheses we may not be wrong in arguing a wide range of versatility and resource. The first of these is "Dolores" (3), a picture-portrait in the best style, of a charming lady sitter, posed naturally with a captivating turn of the head. It is in a light key of soundly gradated tones with one rich accent. The other is "The Showman's Wife" (160). What could you expect her to be? Think of Mrs. Jarley. Think of the out-of-door woman, with her experience of all sorts of people, her consequent tolerance and wisdom, her *bonhomie*, her ample physique. Here she is, every inch of all that; fat, kind, and not unhandsome in a way; the poise of her body suggesting the waddling gait, and permitting at the same time a line of unhackneyed design. Almost as good as these, but not so beautiful as the first nor so fine as the second, is "In Lat. 15° S. (at the Grand Guignol" (69), a horrible monster, with one threatening eye and a pipe too stylish for him. Here is character in full measure. "A Cavalier" (175) has "go" and dramatic force. He looks like a frightened D'Artagnan, if that is not a contradiction in terms. All these are important prints, and will certainly send up the reputation of their author.

Notable Sitters.

The good fortune that attends the portraitist who gets a social lion as sitter is so well understood that the wonder is how few of the notable people are here. Perhaps Walter Benington scores with "Professor Einstein" (45), of whom, however, he has not made anything heroic, but has chosen a representation that is almost commonplace in its homely literality. The giant of philosophy and science seems a little worried about the turmoil and confusion he has caused in the minds of men. "The Rt. Hon. Col. Harvey, U.S.A. Ambassador" (217) and "The Late C. Lovat Fraser" (219) have each their proper characteristics, the former with his ugly goggles, which no official, particularly if an American, seems able in these days to do without; the latter in costume and bearing the perfect dandy. A good bag of notabilities for Mr. Benington. "Rutland Boughton" (100), the musical composer, of Glastonbury fame, falls to Herbert Lambert, who shows him in his ingratiating mood—he has others. The design is masterly. "Mme. Lopokova (Russian Ballet)" (176) comes from Florence Vandamm. The print makes a terribly "contrasty" effect, and by being presented in conditions true to the ballet traditions has sacrificed pictorial charm. The same worker's "Mme. Tchernicheva (Russian Ballet)" (23), is, however, more engaging, and does more justice to Miss Vandamm's skill. N. E. Luboshez gives us "F. J. Mortimer" (264), looking quite a good boy, the uncomplaining martyr to unrecognised labours in photographic causes. Mr. Luboshez's other photographic lion is "Nikola Persheil" (86), whose fame rests upon portraiture of exquisite quality. Then we have Walter Thomas's new departure into professional portraiture publicly heralded by a striking picture of "The Lord Chief Justice of England" (287). Mr. Thomas here succeeds in avoiding all the "stunts" of his successful rivals. He has found a way of his own, which, it a little hard and precise, has the merits of thorough soundness. Everything is rendered with a kind of pre-raphaelite conscientiousness, wig, robes, and all. This is rather an old idea in photography, but new again to-day, and if Mr. Thomas can continue to imbue it with his taste and feeling, he will probably find it popularly acceptable. "J. S. Sargent, R.A." (386), by Sydney Carter, and "The War Correspondent, Fredk. Villiers" (336), by D. U. Jaeger, completes the list of the very eminent sitters, though there are several actors, dancers, and so forth who will be known to the average visitor.

Sitters in General.

Quiet, intensely interesting, and amazingly true in all respects, the portrait of "Sara Holm" (54) must be added to Louis Fleckenstein's past triumphs. He has always been partial to the suggestion of colour, but here, and in "Johnny" (78), he has adopted a distinct formula of coloration, using for the flesh a yellowish tone which is frankly not realistic, but which suits an aged subject. But for these suggestions of colour the show is devoid of all attempts to surpass monochrome, and in this I, for one, think that the committee have taken an advisable course.

L. J. Steele we associate with the East, but he has tripped now to the North, and gives us a striking portrait of "Kai Neilson, Danish Sculptor" (75), at work upon some immense marble figures. It is a case, however, where the sitter is rather overwhelmed and suppressed than otherwise by the environment which is supposed to be a help to the presentment of him. A rather taking idea is shown in C. Wormald's "Portrait of Miss Rhoda Henson" (99), though it is as old as Rembrandt. It is the shading of the brows, so that the eyes are submerged in tone. Photography has not hackneyed this effect so far. This is a beautiful print, with its animated expression and richness of tone in the lady's soft furs. "Miss Ruth Miller" (102), in nun's draperies, is of the nature of a character study, by J. N. Doolittle. "Portrait of Mr. G." (248) differs little in character from N. E. Luboshez's other work already mentioned, except that it shows a remarkable leaning-forward pose, with the head on the hand. W. Crooke's "Study of a Head" (255) is his usual thing. It gains by a distant view-point. Amongst single heads, Estelle's "Portrait of Miss Duffus" (283) is noteworthy for charm.

Recipes.

Styles and "stunts" come and go. Last year we were treated to a profusion of back-lighted portraits in the American manner. This year there are scarcely any, though the Earl of Carnarvon shows a damsel who catches a bright light under the chin and nowhere else. But the recipe of putting a sitter against a wall so that sharp cast-shadow accompanies the figure is still rampant. What is supposed to be its attraction, I wonder? Hugo N. van Wadenoyen, Junr., uses it in "James Whale as Slaney in 'Abraham Lincoln'" (24), L. D. Carter shows it in "Columbine" (113), Charles Borup likewise in "Happy Molly" (117), N. Muray in "Mlle. Desha" (164). L. Fleckenstein's seated figure, called "Lassitude" (227), gives it again. In the same worker's "Shadowgraph" (107), however, there is a *raison d'être* for this resource, for here a delightful figure is making the shadow

of her hands take the form of an elephant in a square patch of light upon the wall, and the whole thing is an agreeable pattern of dark and light tones.

Perhaps more pronounced still is the recipe of the dancing girl, nude or semi-nude, who bends her body back in a spine-breaking curve. It is really time the curtain was rung down on this "turn." It is only rarely that the figure is treated with grace in these acrobatic feats.

The Dancers.

Like the poor, the dancers are always with us; but to my mind they are rather a boring community—they are so dreadfully all alike. True, they range from the clothed and right-minded variety to the mad athletic nude; but we know them all perfectly well. A slight innovation this year comes from A. F. Kales, who places his "Morgan Dancers" (88) before a portal of a most worrying and nondescript style of architecture. His "War Dance" (33), a figure of a Red Indian, in every technical respect a fine thing, has also the drawback of incongruity. We do not expect Red Indians to do war dances on a carpet in a room before a roll-down background. His "Ruth St. Denis" (260) is faultless in this respect, and has a fine sense of motion. H. Borssenbrugge, E. Gropp, H. Arnold, A. Koch, N. Muray, A. Remfelt, E. P. Henry, and others all send dancing themes, some clothed, mostly nude. Some are choice prints, such as Mrs. Y. Park's three "Studies" (222, 225 and 229), and likewise N. Muray's "Abandoned" (41), but, like that example, they seem to become particularly acrobatic and bend their spines back to cracking-point when they happen to be undressed. But there are two examples that have the interest of novelty; one is F. Jay's "Will o' the Wisp" (50), showing a young girl in the midst of a violent leap. It is, I think, the first achievement of so rapid an action by an amateur photographer, of whom it postulates remarkable ingenuity and perseverance. The other novelty is by Helen Macgregor, and shows a damsel who, in voluminous skirts, is "without any visible means of support," both feet and hands being in the air. She is called "Maria Gambarelli" (312). On the whole, there is much to be said for the less volatile pose of H. J. Mettee's "The Dancer" (233), and its splendid quality.

Character Studies.

There is more human nature in the heads that are photographed by invitation, so to speak, than in figure studies. I have already referred to Mr. Crowther's Grand Guignol character, which is the most striking of all; but it is run very close by two other villains, one of whom has also the single eye as a *pièce de resistance*. This is J. N. Doolittle's "Vaqueros" (25), notable for dramatic force and true sunshine effect. Less convincing as a sunlight study, but far more noble as a composition, is Mrs. A. Ralli's "Italian Market Woman" (34), a fine, stalwart figure. This print is the climax of Mrs. Ralli's method—a firm statement of simple light and shade, generalised almost into two tones. There is much to be done with it when in such good hands as hers. W. J. Clutterbuck's old woman drinking "Bouillon" (94) is good, and is cheek by jowl with a queen, "The Great Catherine" (95), a fancy portrait, very cleverly managed, by Dr. H. B. Goodwin, though the action of the model's left arm is not clearly explained. We drop back again to the soil at "The Pedlar" (103)—a study of great merit, marred only by the agressiveness of unimportant illumination on the temple. Pierre Dubreuil sends a curiously treated head of a "Woman at San Remo" (105). She appears to be supporting some burden, of which we only see the dark under surface, and as the bust is vignetted away, a queer stalactite effect is given of a head attached to a ceiling. "Vieja Vasca" (190), by A. Koch, is a capital study of an old woman as far as her face is concerned, but the shawl which surrounds her head and shoulders seems to miss the light that falls upon her features. "Allegro" (207) is an animated figure who, by her bearing, complexion, and ample teeth, is obviously not Circassian. H. Jackson succeeds admirably with an oriental type in "A Chinese Priest" (218), whose eyes are half-closed in an excess of superciliousness. This is a very noteworthy piece of character delineation, splendidly "round" and well-modelled.

Pictorial Studies.

G. M. Brownlee's young lady is far too demure and refined to bear the name of "Audrey" (240). No Touchstone would have been unceremonious with her. "West is East" (285) is the inexplicable title given to a very luscious print by W. F. Brigham. It is a full-face head of a lady, whose eyes look through the material of her headgear—a very taking and original piece of work. "The Adventuress" (290), by Estelle, seems a far safer sort of lady to consort with. Yet her expression is a good psychological study. Is the sparkle of the eyes in the Earl of Carnarvon's pretty girl he calls "Spring" (2) a wee bit overdone? At any rate, the whites of the eyes in Bertram Park's "Study" (263) seem more assertive than they would be in nature. But it is a fine thing, beautiful in modelling, and if it is too lively, that extreme is far more pleasant than the dying girl, "Desha" (21), which N. Muray sends. The figure work of Eng.-Comr. E. J. Mowlam is very full of promise. I like it better than his war work. He has made a fine design of a girl seated on a stool, her knees in her hands; but, like his work generally, it is very gloomy in tone. The title is "Pierette" (51). Another gloomy print, but one of delightful quality, is only partly excused by its title, "The Death" (55). It represents two figures, of which the dying one, posed like the famous Marat dead in his bath, has a "spot light" upon his chest, whilst the lady behind is quite out of the limelight, and is, in consequence, repressed in tone and flattened in modelling, so that she looks more like a monumental effigy than a ministering angel. This depressing state of things is shared by Lionel Wood's otherwise beautiful "Portrait of Miss H." (63). It is finely designed, but, in spite of costly apparel, the lady appears to be in a dungeon. We get relief with the darks of A. Folkmann's "Figure Study" (121) by a stripy scheme of light and shade, helped out by the stripy material of the costume. The result is very strong and effective, because the design built-up of contrasting masses is good.

Suckling subjects have an attraction for camera artists. Perhaps it is that maternal solicitude moves them; perhaps they like to feel that they can respond to the same æsthetic stimuli as moved the old masters, who so often represented the Virgin in this elemental function. I think we can say that the religious impulse is not uppermost in photographers, and can assume, therefore, that the impulsion is a genuine desire to express parental susceptibility in terms of beauty. Certainly H. Berssenbrugge's "Motherhood" (64) is a success in this direction. It is a very fine design, and its presentment is free of all sentimentality. Its red tint gives it an old-mastery look which goes well with the subject. I don't think it has ever been better done by means of the camera. J. M. Buerba adopts the same theme in "Madre Gitana" (35). Here, however, the point of view is that of modern art—the gipsy mother is on the ground—one thinks of the French peasant-painting phase of art, and the sense of design is absent. "The Bride's Dream" (138), by F. Ziegler, is light, soft, and gauzy, with a figure charmingly posed. How different to Hugh Cecil's *apachee*-looking girl, called "Feathers" (139)! which is amazingly strong, but unlovely, and is the third example of the one eye of terror. Her feathers hang off the brim of her hat, and are a feature of the design, as they are also in C. Vandyk's "Mme. P." (155)—a delightful profile. Hugh Cecil's other print, an important work, "Mme. de Kunglo" (147), is the antithesis of his "Feathers." She assumes a demure, mock-modest pose, and is prim to a degree in her dark clothing; but it is not intended that we shall believe in her except as an actress. Another lady is called "Autumn" (156), by the Earl of Carnarvon. She is enchanting, but she has no clothes on at all under her shawl! *O tempora! O mores!* A fine "Profile Study" (196), by Yevonde, errs on the side of hardness. Angus

Basil's "Milton Rosmer" (199), a villain, and Maud Basil's "Claud Mark" (206), a sorrowful gentleman with a big guitar, are both celebrities of "the boards," I suppose. The first has too much of what the other lacks—vim. "The Second Sitting" (216) is a new kind of self-portrait, since its author, J. C. Warburg, has given us a lady sculptor at work upon a bust of the photographer which promises exceedingly well. I must direct admiration to "Estudio" (245), a charming sitter, treated in a way that recalls a powerful point-drawing: and also to Dr. H. B. Goodwin's beautiful "Girl with Mirror" (254). Those who like softness will enjoy the "Girl in Black" (269), sent by Rabinovitch. Its quality is remarkable. H. Felton has caught a momentary action capitally in "The Bromoilist Answers a Question" (270), while the thing to be noted in J. A. Gardner's "Passamaquaddy Indian" (323) is the admirable design of its lines. A word must be said, too, for J. C. Stick's dainty and subtle "Marie" (123), with her basket of flowers; the whole thing almost a silhouette.

F. C. TILNEY.

(To be concluded.)

PARIS NOTES.

THE holiday season has been, as customarily, one of inactivity among photographic societies, but I can now take up again my chronicle of events of special note.

An Exhibition of New Inventions.

On August 26 there was opened in the Esplanade des Invalides the nineteenth annual exhibition of the Association of French Lesser Manufacturers and Inventors, a fixture which is better known under the name of Concours Lepine, in reference to the well-known prefect of police who gave much encouragement to this institution in its early days. Although originally intended for the exhibition of novel toys made by Parisian workmen, the exhibition has long included extremely varied articles and almost always some photographic novelties. Two new models of magnesium lamps are shown by M. F. Pechenot. A feature of both is a very effective automatic catch by which any premature operation of the lamp is prevented. One of the models is fitted with ignition by pyrophorous metal (ferro-cerium); the other by a species of touch-paper, which is employed as a continuous band. Both lamps are provided with a light handle, allowing of holding them at arm's length, and with bushes for attaching them to the photographic tripod.

M. Ch. Dupont has devised an indicator for the speed of movement of the film in the cinematograph projector, the pointer being controlled by a device very similar to the centrifugal regulator of a steam engine. Equipment for photography from a kite is shown by M. L. P. Frantzen, and consists of a strong though light camera, which can be attached to a suitable kite, or can be hoisted up to a kite which has already been raised to the required height and brought down again after exposure of the negative.

Another photographic exhibit is that of the Stampa Company, who for about two years past have been supplying a "citra" sensitiser for application to papers, fabrics, leather or wood. They have now just begun the manufacture of sensitive tissues, and show some fine results of printing on silk and canvas.

New Electric Lamps.

The Compagnie Générale des Lampes of Paris has recently worked out, at the request of several physical laboratories, a tungsten filament lamp of cylindrical form, filled with nitrogen and having the filament constantly stretched in the axis of the cylindrical bulb by means of a spring. The intensity is much greater than that of the filament of a Nernst lamp, and these lamps are of great advantage when it is wished to obtain pencils of light of equal intensity in different directions, as, for example, in many photometric instruments used for the measurement of negatives. The lamps likewise serve for the illumination of the slits of spectrographs, and in some cases may even be used in place of a slit.

For the purpose of increasing the efficiency of the incandescent electric bulbs used for projection, a Parisian maker of projection apparatus, M. E. Mazo, has adopted with great success the plan of silvering the whole surface of the bulb with the exception of a small patch immediately facing the condenser. In consequence of the internal reflection the filament reaches a higher temperature, and, moreover, the light is projected forward in such greater measure that the efficiency of the lamp is increased by more than 50 per cent.

Studies of Ultra-Violet Light.

In the course of experiment on the influence of ozone on the absorption of solar ultra-violet rays by the atmosphere, MM. Ch. Fabry and H. Buisson have undertaken some sensitometric measurements with ultra-violet light, and have obtained some interesting results. In the case of the particular plates employed (Jougla Mauve Label), and within the spectral region studied, viz., 3,150 to 2,900 AU, the development factor or gamma has a constant value, less than half the value obtained under the same conditions of development, for the visible (blue-violet) part of the spectrum. It was also found that the gamma values were slightly different for the above region of the ultra-violet when successive exposures were made at variable intensities for a constant time, and then at a constant intensity for a variable time. The variation of photographic activity in the particular region of the solar spectrum is great; the sensitiveness at 2,975 AU being about 6,000 times greater than at 2,936 AU. Moreover, the measurements of the opacities of photographic films uniformly exposed and developed, show that the opacity is highly variable within this part of the spectrum. A film of opacity 500 in the visible violet has an opacity of only 30 at 3,130 AU, this opacity rising to 400 at about 2,500 AU. The opacity is practically constant in the same part of the spectrum after intensification with mercuric chloride and ammonia, whereby the silver image is almost completely replaced by mercurous amidochloride.

Some Recent Patents.

The recent publication of a French patent of L. Dufay (No. 520,784 of November 30, 1917) throws some light on the mystery which has surrounded the operations of the Versicolor Company, which is the concessionaire of this patent. For the production of photographs in natural colours on paper there is employed, for taking the negative, a transparent mosaic screen in three or four colours of regular geometric pattern and having its units of sufficiently intense colours for making the customary selection. A screen of the same geometric pattern is impressed upon paper but with much weaker colours, this positive screen impression being covered by a sensitive emulsion for positive printing. After development and drying of the negative obtained by exposure of a panchromatic plate through the negative screen, the negative so obtained is laid in register on the screen-coated positive paper, register being judged by the appearance, by transmitted light, of colours complementary to those of the subject. The positive print is then exposed, and, when finished, reproduces, so it is claimed, the colours of the subject.

In France, as is well known, the granting of a patent is made without any examination of the practicability or novelty

of the invention. All that is necessary is that the application and any illustrated drawings shall be made on paper of a certain size. Profiting by this state of things, an "inventor" has transcribed almost verbatim (Patent No. 522,919, of March 12, 1919, granted to M. de Gaudart d'Allaines) an article by Captain A. Calvet, published in 1911 in the "Bulletin of the French Photographic Society" (Series 3, Vol. II. pp. 329-244), on development by means of two dishes. The author of this new patent has confined himself to modifying the formulæ, but the alteration appears to be somewhat ill-judged, for the use of sodium chloride is directed as a restrainer of diamidophenol developer, apparently without recognition of the fact that this salt will then be added to that already formed in the bath by the action of the diamido phenol hydrochloride on the soda sulphite.

L. P. Clerc.

THE SPEED OF A LENS.

[Of the sub-divisions of photographic optics, those which relate to the effect of the stop are of the greatest practical importance, and, fortunately, are those which permit of explanation of the first principles by the use of mathematical symbols or formulæ of the simplest kind. In the present chapter we bring together in this simple form the relation of the stop to the "speed" of the lens. It is first shown how the familiar F. No. is derived from the action of a lens and how the F. No. varies from its nominal value when the object is relatively near to the lens. Older systems of marking the stops of lenses are explained, and the concluding part of the article deals with the two-fold cause of the falling-off of illumination towards the margins of the plate. It is hoped that an occasional article of this kind will contribute to a more exact understanding of familiar working facts and figures by those who are disinclined to include in their reading anything which they regard as "only theory."—Eds. "B.J."]

I.

Intensity of the Lens Image.

It is self-evident that the "speed" of a lens, that is to say, its degree of permitting short times of exposure, is measured by the brightness or intensity of illumination of the image formed by it. Apart from certain minor factors, viz., the number of glasses forming the lens and their colour and thickness, the intensity of the image *at or near the centre of the field* is determined by (1) the area of the diaphragm aperture and (2) the focal length (or image conjugate focal distance) of the lens. The diaphragm aperture determines the volume of the pencil of light transmitted by the lens; the focal length (or focal distance) determines the area over which this light

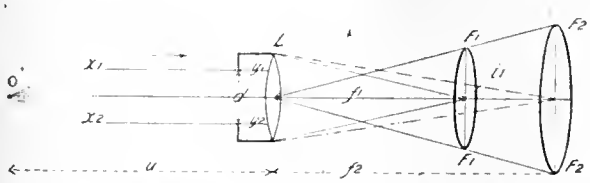

Fig. 1.—Intensity of lens-image in relation to (1) aperture of diaphragm and (2) focal length of lens.

is distributed. Fig. 1 shows how the formula for relative intensity of image is derived from these two quantities.

In fig. 1 a lens L has a diaphragm aperture of diameter d and a focal length of f_1. O represents one point in a uniform and uniformly-lighted object placed at such a distance u from the lens that rays x_1y_1, x_2y_2 are practically parallel when they reach the lens and, therefore, come to a focus at i_1.

It is clear that of all the rays emitted by O, only a cylindrical pencil of diameter d passes through the lens. Similarly from other points in the object (near to the lens axis) pencils of equal sectional area are formed by the diaphragm aperture. Hence the light transmitted by the lens is proportional to the area of the diaphragm aperture, and since the area of a circle is proportional to the square of its diameter the light transmitted is directly proportional to d^2.

Now intensity of illumination is the volume of light reaching a surface divided by the area of that surface. As has just been shown, the volume of light, from a distant uniform and uniformly lighted surface, which is passed by the aperture of a lens, varies according to the area of that aperture; that is, according to the square of its diameter, if it is a circular aperture. The area over which it is distributed depends upon the focal length of the lens.

In the case of an object at such a distance that rays from it are practically parallel when they reach the lens, the scale (linear) upon which the object is reproduced is proportional to the focal length of the lens.* Thus in fig. 1, if we represent the image of the object (or a part of it) formed by the lens L as the circle F_1F_1, the image formed by a lens of focal length f_2 and represented by the circle F_2F_2, will be of greater diameter in the proportion of f_2 to f_1. If the second lens has twice the focal length of L, the image formed by it (of a distant object) will be twice the diameter of that formed by L.

Again, the areas of the respective images are proportional to the squares of their diameters, and, therefore, to the squares of the corresponding focal lengths—that is, f_1^2 and f_2^2. Thus the relative volume of light d^2 is spread over areas which are (relatively) f_1^2 and f_2^2, and hence the relative intensities of the images are:—

$$\frac{d^2}{f_1^2} \text{ and } \frac{d^2}{f_2^2}$$

It will be seen that this holds good in a slightly different form when the object is at such lesser distance from the lens that the rays reaching the diaphragm are no longer parallel but still divergent. In this case (corresponding with the taking of photographs of objects up to within a very short distance of the lens) the illumination of the image is modified from two causes. The light reaching the lens is of greater intensity, in accordance with the law of inverse squares; that is, its intensity is inversely proportional to the squares of the distances u. At the same time the image is formed in a plane at a distance v behind the lens, v being greater than f_1 and increasing proportionately as u becomes less. The linear scale of reproduction of the image is then the ratio $v : u$, and, therefore, the area of the image relatively to the object is the ratio $v^2 : u^2$.

Thus we have:—

Amount of light transmitted by the diaphragm is proportional to $\frac{d^2}{u^2}$

Area over which this light is distributed is proportional to $\frac{v^2}{u^2}$.

Dividing relative amount of light by relative area, relative intensity of illumination of image is

$$\frac{d^2}{u^2} \div \frac{v^2}{u^2} = \frac{d^2}{v^2}.$$

* If the object is at such an immense distance that no increase in focal length magnifies the size of the image, reduction of the intensity of the image by spread of its area obviously does not come into play. The stars are such objects. Hence in stellar photography the intensity of the image is proportional simply to the area of the diaphragm (or rather to that of the telescopic lens) without regard to focal length.

The formula for the intensity of the image is thus the same as that already obtained, except that v (the focal distance when photographing a nearer object) takes the place of f, the focal length.

It is clear that if we wished to mark lenses with numbers indicating, by their greatness or smallness, the "speed" of a lens we should base them on this measure $\frac{d^2}{f^2}$ of the relative intensity of image. For example, a lens of 2-in. diaphragm and 10-in. focal length would receive a number equal to $\frac{2 \times 2}{10 \times 10} = \frac{1}{25}$. It would be twice as fast as one of 2 in. diaphragm and 14 in. focal length, and therefore rated as $\frac{2 \times 2}{14 \times 14} = \frac{4}{196} = \frac{1}{50}$ approx.—since $\frac{1}{25}$ is twice $\frac{1}{50}$.

But, with one or two exceptions, it has been the sensible practice to mark diaphragms with numbers which are related not to their relative speeds, but to the relative times of exposure required by them; which are, in fact, measures of the "slowness" of a lens, or its "inertia," as Hurter and Driffield proposed to call it. Although photographers habitually refer to the "speed" of a lens, the numbers which are commonly used for lens apertures are actually "slowness" numbers. We will return to this question directly.

Effective Diaphragm Aperture.

In the case of a lens with the diaphragm in front of it and receiving parallel rays, as shown in fig. 1, the real or effective aperture—that is, the sectional area of the largest beam of parallel rays which can pass through the lens, is the actual aperture in the diaphragm, sometimes called the nominal aperture. In other cases, however, the effective diameter is greater.

The chief cause of increase of the effective aperture, and the only one which is regularly taken into consideration in the marking of lenses with aperture numbers, is the condensing action of a positive lens placed in front of the diaphragm, as in all doublet and most compound lenses, or when a single lens is used with the diaphragm behind it. Fig. 2 illustrates both the action of a front lens in this respect and the method of measuring the effective diameter. A pencil ab of parallel rays incident on the front lens is rendered convergent by the latter, so that its diameter dd_1 at the diaphragm corresponds with its real diameter ab. In the case of many lenses of large aperture relatively to the focal length, neglect to use ab and not dd_1 as the aperture when determining the F. number may result in the "speed" of a lens being underestimated to an appreciable extent. The error will vary with the focal length

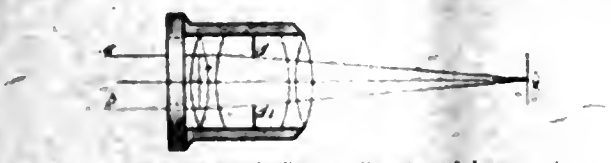

Fig 2.—Measurement of effective diameter of lens aperture

of the front element and also with the distance of the diaphragm from the front element. Miethe has given the following factor for the calculation of the effective diameter, viz., $\frac{f}{f-y}$, where f is the focal length of the front lens, and y the distance of the diaphragm behind the lens. If d is the actual diameter, the effective diameter is

$$d \times \frac{f}{f-y}$$

It is, however, preferable to make a direct measurement (fig. 2). The lens is focussed on a very distant object and the ground glass replaced by a card having a central pinhole aperture in it. In the dark room, a lighted candle or electric bulb is placed close against the pinhole. Since the latter is at the focus of parallel rays, light from the source in this position emerges as a parallel pencil of diameter ab if the diameter of the aperture is dd_1. The pencil may be allowed to impinge on a bit of ground glass pressed against the lens hood and the diameter of the bright disc measured with a pair of dividers; or a scrap of bromide paper may be fixed in the lens cap, exposed there for a few seconds, developed and the diameter of the black disc measured. The diameter so ascertained is the real or effective aperture diameter for the purpose of determining the relative aperture, as described in a subsequent paragraph.

In the case of lenses of all types the effective diameter of the diaphragm aperture, as distinguished from the actual diameter, is presumed to be employed by the makers in determining the relative aperture or f number, and since the practice shows the lens to be of higher "speed" it is not likely to be omitted.

The effect of employing the effective instead of the actual diameter of the stop is to reduce the F. No. in a proportion amounting to as much as 15 per cent. or 30 per cent. according to the type of lens. For example, an anastigmat which has a maximum aperture of $f/4.6$ on the basis of dividing the focal length by the actual diameter of the stop may really have an F. No. of $4.6 \div 1.1 = f/4.2$. The same factor of 1.1 will apply equally to all the smaller stops.

Variation of Effective Aperture with Distance of Object.

Apart from the condensing action of a lens element in front of the diaphragm, described in the preceding paragraph, the effective diameter of the aperture may vary, usually to a very

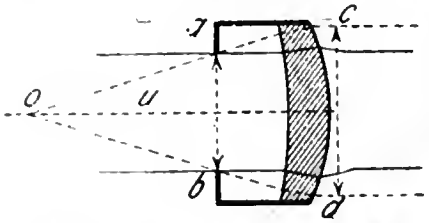

Fig. 3.—Variation of effective aperture with distance of object.

minor extent, when the object is relatively near to the lens, and the incident pencil of rays is therefore divergent. This effect, which has been called "inconstancy of aperture," arises, for example, with a single lens having the diaphragm in front (fig. 3). For practically parallel rays aa, bb from a distant object, the effective diameter is the actual diameter ab. But for rays from an object O at a relatively small distance u, the effective diameter is plainly that of the pencil of rays oc, od, in the plane of the lens, viz., cd. It will thus be seen that the effect varies directly with the distance y of the diaphragm from the lens, and inversely with the distance u of the object. According to C. Welborne Piper, who examined this question, the factor by which the effective aperture for parallel rays should be multiplied in order to give the effective aperture under given conditions is

$$1 + \frac{y}{u}.$$

Since y is usually a small quantity relatively to u, it is obvious that the error which is corrected by the application of this factor is necessarily small. In most cases it is insignificant. The circumstances in which it becomes appreciable are of rare occurrence, *e.g.*, the employment of a single lens (with diaphragm in front) for copying-enlarging direct. Generally the quantity y in the formula is the distance of the entrance pupil of the lens from the node of admission. Since, as a rule, these two imaginary places in a lens are close together, the ratio y/u becomes very small, and the factor approximates to 1. Thus in ordinary calculations relating to the effect of aperture diameter on exposure, depth of focus, etc., it is customary to neglect variations from this cause.

B

Lens Aperture Numbers: F (*i.e. f/d*) Numbers.

Since the intensity of the lens image is proportional to the square of the diaphragm aperture (d^2) and inversely proportional to the square of the focal length (f^2), it follows that, in rating lenses as regards the exposure required, the effect of these two factors needs to be exactly reversed. The exposure, with a given diaphragm aperture, will be proportional to the square of the focal length (*i.e.*, to f^2), and, with a given focal length, inversely proportional to the diaphragm aperture (*i.e.* to d^2). In other words, the measure of the relative slowness of any lens will be $\frac{f^2}{d^2}$.

Opticians, however, have not generally adopted this basis, no doubt for the reason that it yields a wide range of numbers. On this system, for example, $f/4$ would be 16 and $f/32$ would be 1024. Lower numbers and an equal facility of calculating exposures can be obtained in another way, namely, by taking as a basis the ratio f/d, instead of f^2/d^2. On this basis the times of exposure are proportional to the squares of the numbers so obtained, but the necessity of making calculations with the squares of the numbers is avoided by making the diaphragm apertures conform, as regards size, to a standard series of f/d ratios, each representing an *area* of aperture, half the next larger and double the next smaller. By this means lenses are standardised as regards their aperture numbers (with the exception, in many cases, of the largest aperture), and at the same time calculation of exposures with the different stops is made exceedingly simple.

I believe it was the Frenchman, Leon Vidal (1833-1906) who was the first to suggest, about 1860, in his *Calcul des Temps de Pose*, that lenses should be marked with the definite ratio of diaphragm-aperture/focal length. Previously the indications of "speed" were very loose, *e.g.*, "cabinet lens with 1-in. stop." Vidal's suggestion, excellently conceived as it was for making lenses comparable as regards exposure, was, however, only a half-way step. It did not provide against opticians choosing any values of d/f for the series of stops of their lenses, *e.g.*, 1/12, 1/18, 1/20. It provided a relative and comparable measure of the speed of lenses, but it did not remove the necessity of making the awkward "square" calculations when comparing the exposures required with different stops. Opticians, however, perceived the usefulness of doing this for individual lenses, and in 1881 a committee of the (now) Royal Photographic Society recommended the universal adoption of a series of specific aperture ratios; the largest, one-quarter the focal length of the lens and the smaller ones successively half the area of the next larger. Since a disc of half the area of another has a diameter of $\frac{1}{1.4}\left(=\frac{1}{\sqrt{2}}\right)$ of the latter, the series of suggested ratios were:—

$\frac{d}{f}$ (Intensity ratios)	$\frac{1}{4}$	$\frac{1}{5.6}$	$\frac{1}{8}$	$\frac{1}{11.3}$	$\frac{1}{16}$	$\frac{1}{22.6}$	$\frac{1}{32}$	$\frac{1}{45}$	$\frac{1}{64}$

Expressed the other way about, it was suggested that the apertures of all lenses should be so chosen that by dividing the diameters in turn into the focal length the numbers obtained are:—

$\frac{f}{d}$ (F. No.)	4	5.6	8	11.3	16	22.6	32	45	64
U.S. ...	(1)	(2)	(4)	(8)	(16)	(32)	(64)	(128)	(256)

It was provided that the maximum aperture, in cases where it did not happen to be in accordance with this system, should be separately calculated by dividing it into the focal length, and the F No. so obtained marked on the lens.

The Royal Photographic Society further elaborated this system by proposing that the aperture $f/d = 4$ (*i.e.*, $f/4$) should be taken as a unit and the smaller apertures given numbers proportional to the required exposures, yielding the numbers shown in brackets above. This so-called Uniform System (see below) did not become generally employed. Instead, the particular f/d numbers, which previously had been employed by some makers and users of lenses, came into more extended use.

These F. Nos., as we now call them, thus denote the "relative aperture" of a lens, the terms "aperture" or "stop" being often loosely employed as equivalent designations. The customary method of writing these aperture numbers, *e.g.*, $f/4$, $f/8$, is a symbol of the fact that the diameter of the diaphragm is one-fourth or one-eighth the focal length of the lens.

In the technical and commercial writings of Continental opticians it is usual to express this ratio in the inverse form, *i.e.*, 1:8 (*i.e.*, d/f) instead of $f/8$. This inverse value is termed the *clarté* of a lens in France, and the *Lichtstärke* in Germany. The equivalent term, *intensity ratio* and values corresponding thereto, are seldom used by English writers. Even in France and Germany these intensity ratios, in their precise form, have not been commonly marked on lenses since about 1900.

The particular feature of the R.P.S. series of ratios is that it provides apertures of successively doubled area. Hence exposures with the various stops stand in this same simple relation. $F/5.6$ requires twice the exposure of $f/4$, and $f/11.3$ eight times. Similarly, $f/8$ requires a quarter the exposure of $f/16$ and 1/32 of $f/45$.*

Successive multiplication by 2 thus replaces calculations with the squares of the numbers, except in the case of an odd number, *e.g.*, $f/6.8$, for the maximum aperture. For this it is, of course, necessary to ascertain its relation to, say, the next smaller stop on the basis of the squares of the respective numbers. Thus, compared with $f/8$, exposure required by $f/6.8$ is $\frac{6.8 \times 6.8}{8 \times 8} = \frac{46}{64}$, or very nearly $\frac{3}{4}$; whilst the exposure with $f/8$ is $\frac{4}{3}$ times $= 1\frac{1}{3}$ times that with $f/6.8$.

Before leaving the F. No. system of marking of lens apertures it may be pointed out that since the F. No. is $\frac{f}{d}$, the diameter d of the aperture is $\frac{f}{\text{F. No.}}$. It is, therefore, simple to find the diameter of aperture required for any special F. No., since, with a given focal length, the diameter varies inversely as the F. No. Thus, if an F. No. of $f/4.5$ is produced by an aperture of 2-in., the aperture for $f/5.6$ on the same lens will be $2 \times 4.5 \div 5.6 = 1.6$ in. $= 1\frac{5}{8}$ in. very nearly.

Also, the diameter of a diaphragm requiring twice the exposure of another is calculated from the relation that exposure varies inversely as the square of the diameter. If d_1 and d_2 are two diameters and E_1 and E_2 the respective exposures, then

$$\frac{E_1}{E_2} = \frac{d_2^2}{d_1^2}.$$

If E_2 is required to be twice E_1, then

$$d_2^2 = \frac{d_1^2}{2}$$

Therefore $d_2 = \frac{d_1}{\sqrt{2}} = \frac{d_1}{1.4}$

That is, a diameter aperture requires to be divided by 1.4 (multiplied by 10 and divided by 14) in order to give one requiring twice the exposure. For one requiring half the exposure, the diameter is, of course, multiplied by 1.4.

Other Systems of Aperture Numbers.

Although the Royal Photographic Society's system of marking lens apertures with specific f/d values (F. Nos.) is

* It should be noted that the rule above given does not necessarily hold good in all cases. This arises from the variation in sensitiveness exhibited by a plate according to the intensity of light acting on it. Exposure, that is the amount of light-action, is made up of intensity of light I × time, t, of action, and in some circumstances the same effects are not produced by great variations of I and t, whilst maintaining a constant product I × t. The intensities of light passed by the stops $f/4$ and $f/64$, for example, are in the proportion 256:1, but an exposure of 256 seconds at $f/64$ may not produce so great an effect as 1 sec. at $f/4$. Departure from the rule in this direction may be considerable with slow plates and feeble intensities of light, but with rapid plates exposed on outdoor subjects, that is to say, under the customary conditions of photography, variation from the rule of the F. Nos. is usually negligible

now in almost universal use, a number of other systems have come into use from time to time during the past fifty years. These might be allowed to remain in the oblivion which has overtaken them but for the fact that many lenses were issued with apertures marked according to the systems. These lenses exist to-day in the second-hand market, and their aperture markings are frequently a cause of mystification to their purchasers.

In 1881, as already stated, the (now) Royal Photographic Society proposed that a relative aperture of *f*/4 should be taken as the unit, and smaller apertures be given numbers proportional to the required exposures. This was named the "Uniform System," contracted to U.S.; as it was adopted for the longest period for Kodak cameras (made in America) its designation has been confused with "United States." Lenses by leading British and Continental makers are occasionally found with U.S. stops. The system was officially abandoned by the Royal Photographic Society in 1900, when giving its formal approval to the F. No. system already described, which, during some years previously, had been in almost universal use. F. Nos. equivalent to U.S. numbers are:—

U.S. ..	1	2	4	8	16	32	64	128
F. Nos. ..	*f*/4	*f*/5.6	*f*/8	*f*/11.3	*f*/16	*f*/22.6	*f*/32	*f*/45

In 1899 an International Congress of Photography, held in Paris, proposed *f*/10 as the unit aperture, apparently out of respect for the alleged benefits of decimalism. Larger and smaller apertures received numbers proportional to the required exposures, those for the former, therefore, being fractions. It seems that many French lenses were marked according to this system, equivalent values of which are:—

Paris Congress	.125	.15	.25	.3	.5
F. Nos.	*f*/3.5	*f*/3.9	*f*/5	*f*/5.5	*f*/7

Paris Congress ..	1	2	4	8	16	32
F. Nos.	*f*/10	*f*/14	*f*/20	*f*/28	*f*/40	*f*/56

A unit aperture of $f/\sqrt{10} = f/3.16$ was formerly adopted by the firms of Dallmeyer, Goerz and Voigtländer. Smaller apertures were chosen proportional to the required exposures, but differently by the respective makers. As far as can be ascertained, this system was employed by these firms for lenses issued, respectively, in the following periods:—Dallmeyer, 1886-1898; Voigtländer, about 1889-1907; and Goerz, about the same period. The dates may sometimes be of service in approximately fixing the age of a lens. Equivalent F. Nos. are:—

Dallmeyer..	.5	.75	1	1.5	2	2.5	3	3.5	4	5
F. Nos. ..	*f*/2.2	*f*/2.7	*f*/3.16	*f*/3.9	*f*/4.5	*f*/5	*f*/5.5	*f*/5.9	*f*/6.3	*f*/7

Dallmeyer..	5.5	6.5	7.5	10	15	20	25
F. Nos. ..	*f*/7.4	*f*/8.1	*f*/8.7	*f*/10	*f*/12.2	*f*/14.1	*f*/15.8

Dallmeyer	30	40	50	75	100	150	200	250	300	400
F. Nos. ..	*f*/17.3	*f*/20	*f*/22.4	*f*/27.9	*f*/31.6	*f*/38.7	*f*/44.7	*f*/50	*f*/54	*f*/63.6

Goerz ..	2.3	4	6	9	12	24	48	96	192	384	768
F. Nos. ..	*f*/4.8	*f*/6.3	*f*/7.7	*f*/9.5	*f*/11	*f*/15.5	*f*/22	*f*/31	*f*/45	*f*/62	*f*/87.6

Voigtländer	1	1.6	2	4	6	8	16	32
F. Nos. ..	*f*/3.16	*f*/4	*f*/4.5	*f*/6.3	*f*/7.7	*f*/9	*f*/12.6	*f*/18

Voigtländer	64	128	256
F. Nos. ..	*f*/25.3	*f*/36	*f*/50.6

All the above systems resemble that of F. Nos. in being measures of slowness: the lower the aperture number the faster the lens. One system, apart from that of intensity ratio (*clarté* or *Lichtstärke*, *vide ante*) has been used according to which diaphragms were marked with numbers proportional to the relative intensity of the image and, therefore, inversely proportional to the required exposures. In 1890 the firm of Zeiss adopted *f*/100 as the unit aperture (marked No. 1), larger apertures (requiring successively ½, ¼ the exposure, and so on), being marked No. 2, No. 4, No. 8, and so on. Equivalent F. Nos. are:—

Zeiss *f*/100 unit	1	2	4	8	16	32	64
F. Nos. ..	*f*/100	*f*/70.7	*f*/50	*f*/35	*f*/25	*f*/17.5	*f*/12.5

Zeiss *f*/100 unit	128	200	256	320	512	600
F. Nos. ..	*f*/8.8	*f*/7.1	*f*/6.3	*f*/5.6	*f*/4.4	*f*/3.6

Subsequently apertures were marked according to the same system, but with *f*/50 as unit. Equivalent apertures are:—

Zeiss *f*/50 unit	1	2	4	8	16	32
F. Nos. ..	*f*/50	*f*/35	*f*/25	*f*/17.5	*f*/12.5	*f*/8.8

Zeiss *f*/50 unit	64	80	100	128	160	200
F. Nos. ..	*f*/6.3	*f*/5.6	*f*/5	*f*/4.2	*f*/4	*f*/3.5

According to Messrs. Zeiss, lenses marked with these intensity or exposure Nos. were issued only for a few years during the early period of their manufacture of lenses.

Aperture Number Conversion Rules.

To Convert from U.S. Nos. to f/Nos.—Multiply square root of U.S. No. by 4, *e.g.*, U.S. No. 64. $\sqrt{64} = 8$. $8 \times 4 = f/32$.

To Convert from International Congress (C.I.) Nos. to f/Nos.—Multiply square root of I.C. No. by 10, *e.g.*, I.C. No. 16. $\sqrt{16} = 4$. $4 \times 10 = f/40$.

To Convert from Dallmeyer, Goerz or Voigtländer Nos. to f/Nos.—Multiply square root of the Dallmeyer, etc., No. by 3.16, *e.g.*, Dallmeyer No. 100. $\sqrt{100} = 10$. $10 \times 3.16 = f/31.6$.

To Convert from Zeiss Nos. (Unit f/100) to f/Nos.—Divide 100 by square root of Zeiss No., *e.g.*, Zeiss No. 16. $\sqrt{16} = 4$. $100 \div 4 = f/25$.

To Convert Zeiss Nos. (Unit f/50) to f/Nos.—Divide 50 by square root of Zeiss No., *e.g.*, Zeiss No. 16. $\sqrt{16} = 4$. $50 \div 4 = f/12.5$.

Variation of Relative Aperture with Scale of Reproduction.

As has already been shown, if an object is at a comparatively small distance from the lens, such that its image is formed at a distance v from the lens, the relative intensity of the image is $\frac{d^2}{v^2}$. If the object is at such a distance that rays from it are practically parallel at the lens, the intensity is greater, and is $\frac{d^2}{f^2}$. This arises from the fact that in the former case the image is spread over an area which is greater in the proportion of v^2 to f^2.

Hence the exposure required, with a given F. No., varies in the proportion of $v^2 : f^2$ when photographing objects on any scale of reproduction, inclusive of enlarging, with lenses of different focal lengths, but used at the same nominal relative aperture.

There are two methods of making allowance for this fact in calculating times of exposure when copying originals or copying-enlarging. One is to give to the relative aperture the actual value corresponding with the conditions by replacing f by v in the ratio (F. No.) f/d (that is, by dividing the camera extension v by the diameter of the stop), and then to calculate the exposure according to the usual rule that the required exposure is proportional to the square of the F. No. This is inconvenient since the effective diameter may not be known. It is better to use the alternative plan, viz., to base the exposure on the nominal F. No. (as marked on the lens), increasing it according to the camera extension v by multiplying by $\frac{v^2}{f^2}$.

But, as a rule, these calculations are needed when using the same lens and the same stop for different scales of reduction or enlargement, ranging from, say, 1/10 reduction to about 10 times enlargement. In such circumstances it is usual to take as a standard the exposure required when copying an original "same size," and to draw up a scale of the shorter exposures when copying on a reduced scale and of the longer exposures when copying-enlarging. Since in much copying work there is not the necessity to know the scale of reproduction, it is convenient in practical work to mark the camera baseboard so that the extension is an indicator of the exposure which is required compared with that when copying same size.

This is very readily done on the basis that in same-size copying the plate is two focal lengths from the lens, and the

exposure is therefore four times that when copying an original at, say, thirty focal lengths from the lens. With the camera set in focus for same size, a distance equal to the focal length of the lens is measured on the baseboard from the surface of the plate. This is the zero point, *i.e.*, the focus for distant objects. If, now, from this point we make marks at intervals of, say, 1 in. towards the rear (supposing the camera is, as it should be, of the rear-focussing pattern) the exposures required at the various extension marks will be proportional to $(f + 1)^2$, $(f + 2)^2$, and so on. If each of the numbers so obtained is divided by $4f^2$, the result in each case is the number of times of exposure compared with that for same-size copying. An example with a 5-in. lens will make this clear:—

Distance behind focus for distant objects.	Focal Extension.	Relative times of exposure.	Times of exposure compared with that for same size.
inches.	inches.		
1	5 + 1 = 6	$6^2 = 36$	.36
2	5 + 2 = 7	$7^2 = 49$	.49
* *	* * *	* * *	* * *
5 (= *f*)	5 + 5 = 10	$10^2 = 100$	1.0
6	5 + 6 = 11	$11^2 = 121$	1.2
7	5 + 7 = 12	$12^2 = 144$	1.4

But here we are straying somewhat away from the effect of the diaphragm into that of scale of reproduction, and must return to consider another cause of variation in diaphragm aperture, namely, angle of the rays falling on the lens.

G. E. B.

(To be continued.)

FORTHCOMING EXHIBITIONS.

September 10 to October 8.—London Salon of Photography. Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 19 to October 29.—Royal Photographic Society. Secretary, Royal Photographic Society, 36, Russell Square, London, W.C.1.

November 17 to 19.—Bowes Park and District Photographic Society. Particulars from the Hon. Sec., S. Smith, 68, Mannock Road, Wood Green, London, N.22.

December 3 to 17.—Scottish Photographic Circle. Hon. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

1922.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

PHOTOGRAPHIC INSTRUCTION IN MANCHESTER.—The prospectus of the printing and photographic department of the Manchester Municipal College of Technology for the session 1921-22 has just been published, and may be obtained on application to the head of the department, Mr Charles W. Gamble, O.B.E., M.Sc. The department provides a series of courses of instruction in photography and photo-mechanical processes for both those who can attend only in the evenings and those who can undertake systematic study in the day-time. For the latter a full course has been arranged, extending over two sessions, each of 40 weeks, for the purpose of providing thorough preliminary training of those intending to follow some branch of the industry of photography. This course consists of lectures and practical work, and in addition includes instruction at the Manchester High School of Commerce in the elements of business practice. Special emphasis deserves to be laid upon the value of a systematic course of this kind to those intending to earn a livelihood in almost any branch of photography. There must be a great many within, say, twenty miles of Manchester who are between the ages of, say, 17 and 21, and are intending to qualify themselves by a knowledge of the principles and practice of photography. This full-time course provides the means of doing so for an extremely moderate sum. For the classes in particular subjects, such as negative making, portraiture, retouching, bromide printing, etc., and also for those in half-tone and line photo-engraving, the prospectus of the Department should be consulted. The session begins on Monday, October 3.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 29 to September 3:—

VIEW-FINDERS.—No. 23,478. View-finders for photographic cameras. W. J. D. Walker.

ELECTRIC PRINTERS.—No. 22,825. Electric photographic printing or copying machines. J. B. Halden and J. Halden and Co., Ltd.

PROJECTION SYSTEMS.—No. 23,461. Optical projection systems. A. Warmisham.

CINEMATOGRAPHY.—No. 23,425. Motion-picture apparatus. J. Mery.

PHONOGRAPHIC FILMS.—No. 23,275. Production of tone films. P. Dresla and W. Graaff.

CINEMATOGRAPHY.—No. 22,841. Moving-picture machines. F. F. Abbott.

CINEMATOGRAPH-PHONOGRAPH.—No. 23,273. Cinematographic and phonetic machines. P. Dresla and W. Graaff.

CINEMATOGRAPH-PHONOGRAPH.—No. 23,276. Apparatus for taking animated pictures and recording tone oscillations. P. Dresla and W. Graaff.

SOUND-RECORDS.—Nos. 23,118 and 23,120. Photographic apparatus for recording sound. H. G. Matthews.

SOUND-RECORDS.—No. 23,119. Photographic apparatus for reproducing sound. H. G. Matthews.

STEREOSCOPY.—No. 23,440. Means for obtaining stereoscopic pictures. E. H. Wright.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

PATHÉ.—No. 411,956. Cinematograph films, cinematograph apparatus and accessories thereto, all being goods included in class 8. Pathé Frères Cinema, Ltd., 103-109, Wardour Street, London, W.1, merchants and manufacturers.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

LUXURIA.—No. 384,285. Photographic sensitised paper. Paget Prize Plate Co., Ltd., 132, St. Alban's Road, Watford, photographic plate and paper manufacturers. Class 39.

NILTONA.—No. 384,284. Photographic sensitised paper. Paget Prize Plate Co., Ltd., 132, St. Alban's Road, Watford, photographic plate and paper manufacturers. Class 39.

EPCOTAR.—No. 360,701. Carl Zeiss. (Applied for April, 1914.) In class 8.

REGISTRATIONS RENEWED.

ACIFIX.—No. 294,316. John J. Griffin and Sons, Ltd. Registered in 1907 in class 1.

AEROGRAPH.—No. 294,308. The Aerograph Co., Ltd. Registered in 1907 in class 6.

CITOL.—No. 293,546.—Chemische Fabrik auf Actien (vorm E. Schering). Registered in 1907 in class 1.

ILFORD.—No. 294,706. Ilford, Ltd. Registered in 1907 in class 1.

ILFORD.—No. 294,707.—Ilford, Ltd. Registered in 1907 in class 8.

ILFORD.—No. 294,708. Ilford, Ltd. Registered in 1907 in class 39.

IMPERIAL.—No. 293,654. The Imperial Dry Plate Co., Ltd. Registered in 1907 in class 1.

IMPÉRIAL.—No. 294,497. The Imperial Dry Plate Co., Ltd. Registered in 1907 in class 39.

RAJAR.—No. 287,481. Rajar, Ltd. Registered in 1906 in class 39.

SCALOL.—No. 293,843. Johnson and Sons, Manufacturing Chemists, Ltd. Registered 1907 in class 1.

SEPIANA.—No. 294,375. Ilford, Ltd. Registered in 1907 in class 39.

SILVAMAR.—No. 294,685. Carl Zeiss. Registered in 1907 in class 8.

VERICHROME.—No. 293,413. Wratten and Wainwright, Ltd. Registered in 1907 in class 1.

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees" Such non-payment is of course the method adopted by a firm having no further occasion for the use of a mark.

N (HANGING SIGN).—No. 291,997. Houghtons, Ltd. Registered in 1907 in class 1.

ROTONA.—No. 292,948. The Rotary Photographic Co., Ltd. Registered in 1907 in class 39.

CARBOGRAPH.—No. 292,947. The Rotary Photographic Co., Ltd. Registered in 1907 in class 39.

ULTILUX.—No. 294,317. John J Griffin and Sons, Ltd. Registered in 1907 in class 8.

WELLINGTON SPEEDY (LABEL DESIGN).—No. 294,456. Wellington and Ward. Registered in 1907 in class 1.

PUSHASE.—No. 291,795. Fuerst Bros., Ltd. Registered in 1907 in class 1.

ALLOCHROME.—No. 293,412. Wratten and Wainwright, Ltd. Registered in 1907 in class 1.

New Materials.

Etching-Brown Kodura Developing Paper. Made by Kodak, Ltd., Kingsway, London, W.C.

In this new paper the Kodak Company have sought to provide the portrait photographer with a printing material which, as regards speed, comes between the two grades of Kodura at present on the market, namely, that designated in the one case by single letters, A, B, C, etc., and that issued as BB, CC, etc.

A distinctive feature of the new material is the colour of the prints—a cool brown or warm black, as one may equally describe it. This is obtained directly in the developer by the use of a metol-hydroquinone formula, which differs from those commonly employed only in containing a somewhat greater proportion of bromide. The latter, however, owing to the characteristic quality of the emulsion, does not prolong the time of development. On the contrary, prints on the new paper obtain full depth in about two minutes when using the developer preferably somewhat warmer than is the general rule, namely, at a temperature of 68 deg. F.

Compared with bromide paper, Etching-Brown Kodura is, of course, a relatively slow paper. Using a fairly quick-printing negative, we found that we got correctly exposed prints when giving a time of about 10 seconds at a distance of about 18 inches from a 120 c.p. half-watt lamp. It will thus be seen that fairly ample provision of lamp-power in the printing box is required for short exposures, particularly if the negatives incline towards density.

The formula for the developer is:—

Elon (or metol)	60 grs
Soda sulphite, cryst.	3½ ozs
Hydroquinone	240 grs.
Soda carbonate, cryst.	3½ ozs
Potass. bromide, 10 per cent. solution	1 oz. fl
Water, to make	80 ozs

Equal parts of this stock solution and water are mixed to form the working developer.

The results upon the papers, as regards pleasing colour, brilliancy, range of gradation, and surface texture are excellent. It is evident that while giving users the benefit of considerably greater sensitiveness, the makers have succeeded in producing a paper which is highly responsive to the quality in the negative, and in that sense possesses the quality of latitude so much desired in a printing paper.

The paper is made in four varieties, all of thick substance, but two of smooth texture and two of rough. The smooth papers correspond in surface approximately with what is called "velvet" or semi-glossy surface; the rough excellently simulates the natural surface of a paper somewhat resembling that of a good drawing paper. In each surface the paper may be obtained either white or cream, the cream tint enhancing to a remarkable degree the warm colour of the image. There is no doubt that professional photographers will have a great interest in making trial of this new printing medium.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, SEPTEMBER 18.

North Middlesex P.S. Outing—Somewhere in London.

MONDAY, SEPTEMBER 19.

Society of Photographic Writers, Liverpool. Members meet at 8 p.m., at 31, August Road.

South London Phot. Soc. "Story of a Photographer with two Lenses." A. Dordan Pyke.

TUESDAY, SEPTEMBER 20.

Hackney P.S. "General Hints to Beginners." J. J. Beasley.

Manchester Amateur Phot. Soc. "Rothenburg and its Festival Play." Jas. Shaw.

THURSDAY, SEPTEMBER 22.

Hammersmith Hampshire House P.S. "A Four Hundred Mile Walk in Dolomite Tyrol." Jas. Shaw, F.R.P.S.

North Middlesex P.S. "Ireland." C. H. Oakden, F.R.P.S.

SATURDAY, SEPTEMBER 24.

City of London and Cripplegate P.S. Outing to Bankside.

Hackney P.S. City Outing. H. E. Wood.

CROYDON CAMERA CLUB.

The notice-board last week plaintively inquired "Will Somebody Oblige?" All responsible officials were absent, including the president on a walking tour in Devon. He wrote, saying "his movements were uncertain," doubtless not appreciating this would be attributed by members to the virtue of Plymouth gin. Later the secretary drifted in, but revealed nothing in the nature of a fixture. He was told to take off his hat, and otherwise spoken to severely.

They then cast about for a subject, and eventually settled down to a consideration of the exciting circumstances leading up to the threatened extinction of the dry-plate, and it may be recorded in advance that it was unanimously agreed it would survive for many a long day, with or without monkey-gland. All available bearing on the subject was first read—Messrs. Kodak's announcement, Mr. Lambert's letter in the "B.J.," a recent editorial in the "A.P." (so far as it went, considered much to the point), and Messrs. Wellington's jocular counterblast.

Candour, as is usual, marked the discussion, and Mr. Hibbert, who opened it, said that although Messrs. Kodak had ceased to supply or make Eastman plates, Wratten plates at least continued to be manufactured. Possibly the various dry-plates produced by the latter firm met all practical requirements, and if this were so, Messrs. Kodak, in first-class style, had secured a first-class advertisement for a first-class film, at the same time relieving themselves of multiplicity of brands in dry-plates. He had nothing but praise for the Kodak "portrait film," but several, to his knowledge, who had given it a good trial, had reverted to dry-plates for various reasons. For one thing, many retouchers strongly objected to the film.

Mr. Berry said the quality of the film was superb, but in speed it could not compare with the modern ultra-fast dry-plate, a boon, if not an actual necessity, when taking children in the studio. Ease of storage and minimum of weight were also strong points in favour of the later comer. On the other hand, he had found the manipulations more troublesome, and varnishing presented difficulties. He had never worked larger sizes than whole-plate, fearing the slight curvature of the film with long-focus large-aperture portrait lenses might lead to trouble, for here exact coincidence of the sensitive surface and the focussing screen was of great im-

portance. He had also found that if the films were retouched by an artificial light, which gave perceptible heat, they cockled badly if not quite dry. Mr. Hibbert pointed out that if the special contrivances sold for use with the film were employed—somewhat expensive, by the way—manipulations were as simple as with glass plates. Mr. Berry said he had not used them.

The ever-cheerful Mr. Keifer apprehended an immediate declaration of war between the U.S.A. and this country, with the battle-cry "Films *versus* Plates!" Mr. Sellors failed to understand what all the hullabaloo was about. Messrs. Kodak had a perfect right to give up making dry-plates if they so chose, and photographers had an equal right to use what they preferred. Personally, he should continue in the dear old senile way. He agreed with Mr. Berry that the films were easily stored, a direct incentive to professionals to carry a larger stock of old negatives than would be the case with the far more bulky glass plates. When the fire insurance companies tumbled to the fact that thousands of celluloid negatives might be on the shelves, they would certainly have something to say. Mr. Salt endorsed the favourable opinions expressed about the portrait film, and had an equally good word for the "commercial" brand. He had been much interested in Mr. Hibbert's opening remarks. If the facts were as stated, it seemed that a good many unsuspecting souls were having their legs badly pulled. Others also spoke; some to the point. The debate closed at a somewhat late hour, the chairman, Mr. F. C. Reynolds, proposing a hearty vote of thanks to all who had not contributed to it.

News and Notes.

KALOSAT LENSES.—A prospectus of these quartz soft-focus lenses of the Hanovia Chemical and Manufacturing Co., Newark, N.J., comes to us from Ad. Harz, Weggiss, Switzerland, sole agent for the lenses in Europe.

CITY GUILDS MEDAL.—The silver medal offered in the final examination in photography held by the City and Guilds of London Institute, in May last, has been awarded to Mr. Philip Brain, a member of the Royal Photographic Society and a student in the photographic school of the Regent Street Polytechnic.

STOLEN KODAK.—An Autographic Kodak, No. 5,593, Special No. 1, fitted with Bausch Kodak *f*/6.3 anastigmat in Velosto shutter and contained in a velvet-lined leather case, was stolen from an omnibus in London last week. Any dealer to whom the camera may be offered is asked to communicate with Captain Donald, 21, Rotherwick Road, London, N.W.11.

AIR BRUSH CONTROLLED BY SLOPE.—An American scientific journal states that an air brush that atomises its liquid contents in the usual manner by means of compressed air, has a special feature of control that depends entirely upon the manner in which the brush is held. The intensity of the spray is regulated by inclining the brush, more or less, according to the pressure required. The greater the angle of inclination the more will the colour be divided. The spray is stopped by simply restoring the brush to its normal position.

PHOTOGRAPHS TO PROVE PROPER PACKING.—A machinery-manufacturing concern in Massachusetts has found a new use for photography. Before putting on the cover of a box the contents are photographed to show that they are securely and properly packed. One of the prints is kept by the shipper, while the other is forwarded to the consignee. In the event of damage in transit, both the shipper and the customer have proof that it was not due to negligence in packing. The consignee's print is valuable, also, as a guide in unpacking complicated machinery.

THE BEST LONDON VIEWS.—During a correspondence in the London newspapers last week, in which the most pictorial scenes to be found in London were discussed, the "Daily Graphic" published some little known views taken in the Parks. These landscapes must have come as a pleasant surprise even to those who claim to know London well; one of the views taken in Kensington Gardens near by Lancaster Gate was most picturesque, reminding one of Versailles. Publishers of picture postcards will no doubt benefit by the correspondence and the publication of the pictures.

ALDIS SOFT-FOCUS ATTACHMENT.—Messrs. Aldis Bros., Sarehole Road, Sparkhill, Birmingham, offer to send for stamps sufficient to cover postage a booklet containing an actual photograph showing the soft-focus effect obtained by the diffusion device which can be fitted to the larger lenses of the *f*/4.5 Series I. at the extra cost of 22s. over the price of the lens in ordinary iris mount. The attachment is of considerable value in portraiture, and has the further advantage of giving pleasantly diffused landscape negatives whilst using a lens which is of the light and compact type convenient for outdoor work.

FOUR HUNDRED PORTRAITS OF WOULD-BE BRIDES.—Matrimonial agencies and beauty shows have their opponents, but one must admit that they bring grist to the photographer's mill. Last week's newspapers told of a man in far away Vancouver who wrote to the Mayor of Brighton asking him to find him a wife. The letter to the Mayor was published in the Press, and four hundred letters from would-be brides were sent to Brighton, and the letters, with all the enclosed photographs ("some of them very pretty girls," says the Mayor) are to be sent to Vancouver, where the lonely young man will be for some time busily engaged in reading the letters and examining the many photographs.

COSTLY PROMISES.—So few photographers keep their promises to send snapshots, that it is quite refreshing to hear of one who has. A writer in the "Star" says:—"Photography is certainly a delightful hobby, but don't let it run away with you. This year on my holiday I took snaps of everything and everybody, and thought what a delightful lot of little pictures I should be able to paste in my holiday memory book kept for that purpose. But, alack and alas! everyone 'snapped' wants a print, and not having the time to develop or even print my own films, I find myself faced with a stupendous bill and the trouble of sending the snaps away to the various people who figure therein. Verily I shall think before I snap another year!"

DYE-PRINTING PAPER.—A recent German patent, No. 337,173, of the Badische Anilin Company, describes the preparation of a sensitive printing paper by means of the compounds obtained by precipitating certain acid dyes with aromatic paradiamino componnds. According to the specification, the coating mixture is made by mixing together 100 parts of 30 per cent. blanc fixe paste (barium sulphate) and 10 parts calcined soda, with 100 parts of water. To this is added a solution of 20 parts eosine A (free from salt) in 2,000 parts of water, and 880 parts of 2 per cent. benzidine hydrochloride added. A solution of 40 parts manganese nitrate in 40 parts of water is added to the mixture, which is coated on to glass or paper by means of a binding medium, such as gelatine or albumen. After exposure to light the image is fixed with borax or sodium phosphate or barium hydrate. Bluish red prints are obtained, which may be changed to a red chalk colour by means of a weak solution of calorine.

Commercial & Legal Intelligence.

NEW COMPANIES.

ART PRODUCTS, LTD.—This private company was registered on September 6, with a capital of £1,000 in £1 shares (500 "A" and 500 "B" ord.). Objects: To carry on the business of manufacturers or retail dealers in art reproductions, picture frames, prints, photogravures and engravings, photographic and cinematographic goods, etc. The first directors are: D. B. Buckland, 14, Aeroville, Colindale Avenue, Hendon, N.W.; H. J. Buckland, The Gables, Wantage Road, Lee. S.E., art dealer; S. A. Hart, 23a, Holford Square, W.C. electro plater; Samuel Reinish, 134, Bedford Street, E., sculptor. Secretary: D. B. Buckland. Registered office: 43, Clerkenwell Road, E.C.

FILMS VERSUS PLATES.

To the Editors.

Gentlemen,—It seems to me that the policy of Messrs. Kodak of giving up the manufacture of dry plates in favour of flat films is their own private affair and need not trouble photographers very much. They ought to know better than we possibly can whether their new venture will pay them. But the place where the films are made does seem to be some concern of ours, for I fancy many of us would prefer to buy British goods if we can, price and quality being equal, so that I hope the flat film will be eventually made at Harrow, and that if it is not, those who wish can use other flat films "made in England."

The advantages of glass plates, or celluloid films, as the support of the negative image, will no doubt be a theme for discussion for a long time. Both have their good and bad points. On the whole, I am inclined to think the balance of advantage is with the films, but they have certain disadvantages. None that I have used are as rapid as the quickest plates, and in winter for children we have often been obliged to use dry plates. This disadvantage can be overcome no doubt.

Then there is the great difficulty of holding films rigid and flat during exposure. This is not a great difficulty in sizes up to half-plate, but above that size it is a serious disadvantage, and so far I have seen nothing on the market that would hold a 12 x 10, for instance. This again may be overcome in time.

Several of the difficulties mentioned by your correspondents have not troubled me, and I have been using the films for quite two years; we have found no difficulty in retouching if a black card with a hole in it is laid on the film while in the desk. This is an old arrangement we have used for a good many years when retouching a large group negative; it is an excellent device for preventing eyestrain. At first it is true retouchers complained of the film, but now they prefer them to a glass negative; they like the slight spring of the film.

When wet, the films need a little more care to prevent scratching, but a good dose of alum as soon as possible after fixing saves many defects, and also helps to hasten drying in damp weather. I think the alum prevents a good deal of damage to both back and front in the way of scratches and finger marks, and I think also a well-hardened film resists damp and wear better than one not hardened. I have not been troubled with scratches after the surface is dry, nor with damp, but I can imagine, if placed in an enlarging lantern with a condenser, they might suffer from the heat of the lantern, especially in winter, unless the film was quite free from damp.

This points to one of the disadvantages of the film, namely, the difficulty of protecting the surface with a good varnish; so far, I have found nothing quite satisfactory. Dipping in water-varnish made with borax and shellac, so as to protect both sides, proved a failure, as in a month or two the shellac turned white and opaque in patches. Gold size thinned with turpentine was not a success.

The power to work on back and front of the negative is a great advantage, and also to print from either side; but if it is necessary to use matt varnish the film must be attached to glass. Another advantage is the possibility of cutting negatives up to make a composite; the block makers find this very useful, I believe.

We do not find any difficulty in fastening them down when vignetting; a narrow strip of surgical rubber plaster will hold them firmly, and it can be peeled off without making any mark. Their lightness and unbreakableness (what a word) is another gain in storage and in sending by post. On the whole then, I think I should be sorry to have to give them up, but the proposed new regulations for the storage of celluloid, as set forth on pp. 540, 541 of your issue of September 9, if carried out, will put the users of films in a very difficult position. We are told the "stocks of celluloid shall be kept in a suitable place outside the workrooms plainly marked 'celluloid store.' *Stocks exceeding one hundredweight shall only be kept in a chamber of fire-resisting materials, in which no open light or fire shall be allowed, and which shall not be used for any other purpose than the storage of celluloid.*"

A comparatively small business would soon accumulate a hundredweight of film negatives, but how many such establishments could afford to set up a fireproof room devoted entirely to the storage of negatives?

Even now the storage of a small quantity of film negatives may invalidate an insurance policy. These new regulations if they come into force, and there seems no reason to doubt that they may, will make many professional photographers hesitate before giving up glass plates in favour of films, and those who are using films will have to consider, very seriously, whether they will be able to continue doing so.—Yours truly.

HAROLD BAKER.

Birmingham, September 10.

To the Editors.

Gentlemen,—Noticing your letter signed Mr. Andrew C. Glover, I would like to point out that I have been a constant user of the film since its advent on the market, using not one grosa but grosses. I cannot agree with Mr. Glover when he states that the film is a "nuisance to retouch." On the contrary, it is a pleasure to do so in comparison to a plate, and owing to the fineness of the grain of the film there is less modelling to be done as compared with plates. In respect to scratches and picking up dirt, this can only be caused by careless working (which, alas, applies to plates). I am simply writing this letter as a fair criticism of Mr. Glover's letter.—Yours faithfully, ALEX. S. WARD.

Boston Studios, 38, Newington Butts, S.E.11.
September 12.

To the Editors.

Gentlemen,—I have read with interest the letters in the "B.J." re Kodak film. I write as an enthusiastic user of Eastman Portrait Films, which I have used over a year, and find infinitely superior to glass plates as regards a delightful rendering of half-tones, loss of halation, portability and saving of storage space, but the one serious drawback is their inflammability. I have not yet decided the safest method of storage; also I begin to wonder how one is to get rid of "back numbers." Will the dustman reject them; if so, what is to become of them?—Yours truly,

(MISS) VIOLET K. BLAIKLOCK.

18, Elsworthy Rd., South Hampstead, N.W.3.
September 12.

To the Editors.

Gentlemen,—It would be interesting to learn what justification exists for the implication conveyed in Mr. Mallinson's letter that films are slower than plates, so much so, indeed, that he expresses pity for the photographer who has to use them in dull weather. I see no reason why an emulsion should be slower on a film than on a plate, and, in my own experience, I have not found it so. Moreover, I know of a large, high-class establishment with a specialty for child portraiture where films have ousted plates for some time past.

Perhaps because my experience with plates has been so much larger than with films, I have not found the manipulation so easy with the films, but the freedom from halation more than compensates for this. The evil of halation is not confined to weakening or fogging of adjacent dark shadows, but shows itself also in light drapery, and even on the face, where delicate half-tones are filled up, or obscured and all sparkle destroyed, by light reflected from the back of the plate.

Irradiation, as differentiated from halation, may exist in a film, as in a plate; but in a plate, unless thoroughly well backed, you may have the two evils instead of the one.—Yours faithfully,

Hampstead, W. E. DEBENHAM.
September 12.

THE KODAK MANUFACTURING POLICY.

To the Editors.

Gentlemen,—Why are your contributors up against progress? Surely a firm like Kodak, Ltd., would not discontinue plate manufacture if their portrait films were not giving results far superior to those obtainable on glass plates. Are not the points raised trivial? They are easy to retouch, and both sides are usable for this process. I have no trouble with the retouching, as films lie flat under four small clips which are attached to the desk. Why be troubled with damp if each film is bagged properly? And as to dirt attaching, whose fault is this? Has your correspondent tried benzine for cleaning? Why clean at all, if proper care has been taken during developing, etc.? As to lighting in the studio, can your correspondents obtain negatives, giving correct renderings of detail under all conditions, on glass plates? I doubt it. In conclusion, I may mention I do not tank films, nor do I use clips, etc.; it is quite easy to develop two dozen portrait films in a 12 × 10 dish at one time, and obtain negatives entirely free from scratches. Anyhow, films are "it" all the time, and a boon to all artistic workers.—Yours faithfully,

E. E. CARTER.

Cottage Studio, Romford, September 9.

To the Editors.

Gentlemen,—Personally, I always feel grateful to the Kodak Co. for all their pioneer work for the profession, and I will say this for their advertising matter: Never once have I found them making a statement that was not supported by scientific facts.

I have used the Eastman portrait film for nearly two years, with the greatest satisfaction. I prefer film to glass, because, in my hands, it is easier to do the best work on it, and the cost in cash and *time* is less all the way through.

So far, the faults found with film appear to be almost childish. The correspondent who scratches his films and then allows the dust to get in should learn how not to scratch them. The man who, by "careful" lighting, never gets halation on glass plates is deluding himself.

I prefer to knife or pencil a film, and have found no difficulty in making many hundreds of negatives free from all flaws. I honestly advise all photographers to take up film. Just a little care in adapting one's method of working is all that is necessary, remembering that nothing is perfect in this world, whether it is made of glass, celluloid, or gelatine.

I well remember an old wet-plate man, who, when I made him a negative on a dry plate, fetched his focussing glass to show me the "grain." Was he old-fashioned?—Yours faithfully,

PAUL COE.

Eastgate Street, Gloucester, September 8.

SYSTEMATIC BROMIDE PRINTING.

To the Editors.

Gentlemen,—I am very much obliged to Mr. Harold Baker and Mr. Ainger Hall for their remarks concerning my paper. With the former I am in disagreement in reference to his suggestion of adopting "a standard period for the total time of development," together with a suggested minimum of three minutes. It is impossible to adopt a fixed time of development, because of the influence of temperature, developer variations, and paper peculiarities as between different makes of paper and different batches of the same make. I have had a specimen of Kodak bromide paper which was fully developed with amidol in 1 minute at 65 deg. F., and which toned to a cold sepia. A specimen of Criterion bromide paper developed in amidol of the same strength at 45 deg. F. took 14 minutes to reach the *same* degree of development and tone subsequently to a very similar sepia. It is because of this extreme variation in the total time of development required under varying conditions that I have advocated factorial development as the only satisfactory substitute for either inspection or pure time methods. It is as unsound to adopt a fixed time of development for bromide paper as it is in the case of plates. I can tell Mr. Baker what would be the colour of the prints (when toned) whose measurements were given in Table II., "B.J.," September 2, p. 519. Print E would have been yellow, F warm sepia, G cool sepia, and H very cold sepia. The following factors, amongst others, influence the colour of the print upon toning:—(a) The type of negative (b) the make of bromide paper, (c) the batch of bromide paper (d) the type of bleacher, (e) the degree of development. Factors (b) and (c) admit of no control on the part of the photographer he has to take what the manufacturer gives him. Factors (a) (d), and (e) are under fairly satisfactory control. Factor (e) is best controlled by developing factorially. A short development (low factor) helps to yield a warm sepia. A long development (high factor) helps to yield a cold sepia upon toning. The low factor for amidol (Kodak formula) is 10, and the high factor about 20. The former factor requires double the exposure of the latter in order to yield a print of the same depth. It is sufficient to express the *degree* of development, and let the exposure look after itself. With the high degree of development, the exposure must of necessity be short, or else the print would be black all over, or, at any rate, too dark; and similarly with a short development time, the exposure must of necessity be full, or else the print will be too light. I prefer to describe the ultimate sepia tone as dependent upon the degree of development, and not upon the amount of exposure, since a description of the degree of development is also a very precise description of the amount of exposure for any stipulated depth of print (see rule 2, "B.J.," September 2, p. 520, col. ii). In my experience, the only way to ensure a repetition of the same shade of sepia in prints made upon the same paper from the same negative is to develop each print to exactly the same Watkins factor. The choice of a fixed total time of development cannot accomplish this. If in this latter statement I am wrong, then it follows that the amount of exposure and the degree of development have neither of them anything to do with the final tone of sepia. By common consent they do influence the final tone.

Mr. Hall's trial exposure strip of 5, 7, 10, 15, 25, and 40 seconds is a very wide one. If perchance the 5 seconds exposure were the correct one, then the time of first appearance of the image would be that of the 40 seconds exposure, or eight times normal. Such a wide trial strip should be regarded as a guide to another trial strip rather than a guide to the final print. In my own practice I make a trial strip upon which three exposures are included, one about half what I guess should be about right, another coinciding with my guess, and the third double the guessed exposure. In such a range of exposures (1—3) there is very little difference between the time of appearance of the highest and lowest exposures on the trial strip. The prints quoted in Table II., already referred to, illustrate this. Let us assume that the exposures given to prints F, G, and H were upon one trial strip, namely, 30, 15, and 10 seconds respectively, and let us assume that 15 seconds was about right. The time of first appearance would be that of the 30-second exposure = print F = 6 seconds (Table II.). To be a correct guide to the development of the 15-second exposure it should have been 8 seconds, as in print G (Table II.). With a Watkins factor of 12, this is an error of 24 seconds in a total development time of 96 seconds, or about 25 per cent.—very different to Mr. Hall's suggested "latitude of several hundreds per cent. in estimating the time of development." To be a reasonably good guide to the exposure for the final print, a trial strip must be fairly near the mark, and must not include a very gross over-exposure. If it proves, upon development to the chosen Watkins factor, to be badly out at the over-exposure end, then obviously it must simply serve as a guide to another trial strip.

I had hoped, gentlemen, that your challenge of my statement that within certain limits the product of the exposure given and the time of development required to produce a print of the same depth and appearance is a constant, would have produced some comment. I claim it to be true, and I believe that the first hint of its truth appeared in the parallel curves yielded by bromide paper when the exposures are plotted against the reflection densities, attention to which was called by Messrs. Mees, Nutting, and Jones in 1915. If during development the inertia of the paper shows regression and the paper curves maintain the same slope, then obviously exposure and development can, within limits, take the place of one another. And it happens to be a practical fact that they can do so in a regular manner, so that their product for a succession of prints of the same depth is a constant. That rule bridges the gap between the expert and the beginner, and it can be communicated from the former to the latter in a precise and definite manner. I
